LIST OF PLATES.

OBJECTS AND RULES

OF

THE ASSOCIATION.

OBJECTS.

The Association contemplates no interference with the ground occupied by other institutions. Its objects are:—To give a stronger impulse and a more systematic direction to scientific inquiry,—to promote the intercourse of those who cultivate Science in different parts of the British Empire, with one another and with foreign philosophers,—to obtain a more general attention to the objects of Science, and a removal of any disadvantages of a public kind which impede its progress.

RULES.

Admission of Members and Associates.

All persons who have attended the first Meeting shall be entitled to become Members of the Association, upon subscribing an obligation to conform to its Rules.

The Fellows and Members of Chartered Literary and Philosophical Societies publishing Transactions, in the British Empire, shall be entitled, in like manner, to become Members of the Association.

The Officers and Members of the Councils, or Managing Committees, of Philosophical Institutions shall be entitled, in like manner, to become Members of the Association.

All Members of a Philosophical Institution recommended by its Council or Managing Committee shall be entitled, in like manner, to become Members of the Association.

Persons not belonging to such Institutions shall be elected by the General Committee or Council, to become Life Members of the Association, Annual Subscribers, or Associates for the year, subject to the approval of a General Meeting.

Compositions, Subscriptions, and Privileges.

Life Members shall pay, on admission, the sum of Ten Pounds. They shall receive *gratuitously* the Reports of the Association which may be published after the date of such payment. They are eligible to all the offices of the Association.

Annual Subscribers shall pay, on admission, the sum of Two Pounds, and in each following year the sum of One Pound. They shall receive *gratuitously* the Reports of the Association for the year of their admission and for the years in which they continue to pay *without intermission* their Annual Subscription. By omitting to pay this subscription in any particular year, Members of this class (Annual Subscribers) *lose for that and*

all future years the privilege of receiving the volumes of the Association *gratis:* but they may resume their Membership and other privileges at any subsequent Meeting of the Association, paying on each such occasion the sum of One Pound. They are eligible to all the Offices of the Association.

ASSOCIATES for the year shall pay on admission the sum of One Pound. They shall not receive *gratuitously* the Reports of the Association, nor be eligible to serve on Committees, or to hold any office.

The Association consists of the following classes:—

1. Life Members admitted from 1831 to 1845 inclusive, who have paid on admission Five Pounds as a composition.
2. Life Members who in 1846, or in subsequent years, have paid on admission Ten Pounds as a composition.
3. Annual Members admitted from 1831 to 1839 inclusive, subject to the payment of One Pound annually. [May resume their Membership after intermission of Annual Payment.]
4. Annual Members admitted in any year since 1839, subject to the payment of Two Pounds for the first year, and One Pound in each following year. [May resume their Membership after intermission of Annual Payment.]
5. Associates for the year, subject to the payment of One Pound.
6. Corresponding Members nominated by the Council.

And the Members and Associates will be entitled to receive the annual volume of Reports, *gratis*, or to *purchase* it at reduced (or Members') price, according to the following specification, viz.:—

1. *Gratis.*—Old Life Members who have paid Five Pounds as a composition for Annual Payments, and previous to 1845 a further sum of Two Pounds as a Book Subscription, or, since 1845, a further sum of Five Pounds.

   New Life Members who have paid Ten Pounds as a composition.

   Annual Members *who have not intermitted* their Annual Subscription.
2. *At reduced or Members' Prices*, viz. two-thirds of the Publication Price.—Old Life Members who have paid Five Pounds as a composition for Annual Payments, but no further sum as a Book Subscription.

   Annual Members who have intermitted their Annual Subscription.

   Associates for the year. [Privilege confined to the volume for that year only.]
3. Members may purchase (for the purpose of completing their sets) any of the volumes of the Reports of the Association up to 1874, *of which more than* 15 *copies remain*, at 2*s*. 6*d*. per volume.[1]

Application to be made at the Office of the Association, 22 Albemarle Street, London, W.

Volumes not claimed within two years of the date of publication can only be issued by direction of the Council.

Subscriptions shall be received by the Treasurer or Secretaries.

[1] A few complete sets, 1831 to 1874, are on sale, £10 the set.

Meetings.

The Association shall meet annually, for one week, or longer. The place of each Meeting shall be appointed by the General Committee two years in advance; and the arrangements for it shall be entrusted to the Officers of the Association.

General Committee.

The General Committee shall sit during the week of the Meeting, or longer, to transact the business of the Association. It shall consist of the following persons:—

CLASS A. PERMANENT MEMBERS.

1. Members of the Council, Presidents of the Association, and Presidents of Sections for the present and preceding years, with Authors of Reports in the Transactions of the Association.

2. Members who by the publication of Works or Papers have furthered the advancement of those subjects which are taken into consideration at the Sectional Meetings of the Association. *With a view of submitting new claims under this Rule to the decision of the Council, they must be sent to the Secretary at least one month before the Meeting of the Association. The decision of the Council on the claims of any Member of the Association to be placed on the list of the General Committee to be final.*

CLASS B. TEMPORARY MEMBERS.[1]

1. Delegates nominated by the Corresponding Societies under the conditions hereinafter explained. *Claims under this Rule to be sent to the Secretary before the opening of the Meeting.*

2. Office-bearers for the time being, or delegates, altogether not exceeding three, from Scientific Institutions established in the place of Meeting. *Claims under this Rule to be approved by the Local Secretaries before the opening of the Meeting.*

3. Foreigners and other individuals whose assistance is desired, and who are specially nominated in writing, for the Meeting of the year, by the President and General Secretaries.

4. Vice-Presidents and Secretaries of Sections.

Organizing Sectional Committees.[2]

The Presidents, Vice-Presidents, and Secretaries of the several Sections are nominated by the Council, and have power to act until their names are submitted to the General Committee for election.

From the time of their nomination they constitute Organizing Committees for the purpose of obtaining information upon the Memoirs and Reports likely to be submitted to the Sections,[3] and of preparing Reports thereon, and on the order in which it is desirable that they should be read, to be presented to the Committees of the Sections at their first

[1] Revised by the General Committee, 1884.

[2] Passed by the General Committee, Edinburgh, 1871.

[3] *Notice to Contributors of Memoirs.*—Authors are reminded that, under an arrangement dating from 1871, the acceptance of Memoirs, and the days on which they are to be read, are now as far as possible determined by Organizing Committees for the several Sections *before the beginning of the Meeting.* It has therefore become necessary, in order to give an opportunity to the Committees of doing justice to the several Communications, that each Author should prepare an Abstract of his Memoir, of a length suitable for insertion in the published Transactions of the Association, and that he should send it, together with the original Memoir, by book-post, on or

meeting. The Sectional Presidents of former years are *ex officio* members of the Organizing Sectional Committees.[1]

An Organizing Committee may also hold such preliminary meetings as the President of the Committee thinks expedient, but shall, under any circumstances, meet on the first Wednesday of the Annual Meeting, at 11 A.M., to nominate the first members of the Sectional Committee, if they shall consider it expedient to do so, and to settle the terms of their report to the General Committee, after which their functions as an Organizing Committee shall cease.[2]

Constitution of the Sectional Committees.[3]

On the first day of the Annual Meeting, the President, Vice-Presidents, and Secretaries of each Section having been appointed by the General Committee, these Officers, and those previous Presidents and Vice-Presidents of the Section who may desire to attend, are to meet, at 2 P.M., in their Committee Rooms, and enlarge the Sectional Committees by selecting individuals from among the Members (not Associates) present at the Meeting whose assistance they may particularly desire. The Sectional Committees thus constituted shall have power to add to their number from day to day.

The List thus formed is to be entered daily in the Sectional Minute-Book, and a copy forwarded without delay to the Printer, who is charged with publishing the same before 8 A.M. on the next day in the Journal of the Sectional Proceedings.

Business of the Sectional Committees.

Committee Meetings are to be held on the Wednesday at 2 P.M., on the following Thursday, Friday, Saturday,[4] Monday, and Tuesday, from 10 to 11 A.M., punctually, for the objects stated in the Rules of the Association, and specified below.

The business is to be conducted in the following manner :—

1. The President shall call on the Secretary to read the minutes of the previous Meeting of the Committee.
2. No paper shall be read until it has been formally accepted by the Committee of the Section, and entered on the minutes accordingly.
3. Papers which have been reported on unfavourably by the Organizing Committees shall not be brought before the Sectional Committees.[5]

At the first meeting, one of the Secretaries will read the Minutes of last year's proceedings, as recorded in the Minute-Book, and the Synopsis

before........................., addressed thus—'General Secretaries, British Association, 22 Albemarle Street, London, W. For Section ....' If it should be inconvenient to the Author that his paper should be read on any particular days, he is requested to send information thereof to the Secretaries in a separate note. Authors who send in their MSS. three complete weeks before the Meeting, and whose papers are accepted, will be furnished, before the Meeting, with printed copies of their Reports and Abstracts. No Report, Paper, or Abstract can be inserted in the Annual Volume unless it is handed either to the Recorder of the Section or to the Secretary, *before the conclusion of the Meeting.*

[1] Added by the General Committee, Sheffield, 1879.

[2] Revised by the General Committee, Swansea, 1880.

[3] Passed by the General Committee, Edinburgh, 1871.

[4] The meeting on Saturday was made optional by the General Committee at Southport, 1883.

[5] These rules were adopted by the General Committee, Plymouth, 1877.

of Recommendations adopted at the last Meeting of the Association and printed in the last volume of the Transactions. He will next proceed to read the Report of the Organizing Committee.[1] The list of Communications to be read on Thursday shall be then arranged, and the general distribution of business throughout the week shall be provisionally appointed. At the close of the Committee Meeting the Secretaries shall forward to the Printer a List of the Papers appointed to be read. The Printer is charged with publishing the same before 8 A.M. on Thursday in the Journal.

On the second day of the Annual Meeting, and the following days, the Secretaries are to correct, on a copy of the Journal, the list of papers which have been read on that day, to add to it a list of those appointed to be read on the next day, and to send this copy of the Journal as early in the day as possible to the Printer, who is charged with printing the same before 8 A.M. next morning in the Journal. It is necessary that one of the Secretaries of each Section (generally the Recorder) should call at the Printing Office and revise the proof each evening.

Minutes of the proceedings of every Committee are to be entered daily in the Minute-Book, which should be confirmed at the next meeting of the Committee.

Lists of the Reports and Memoirs read in the Sections are to be entered in the Minute-Book daily, which, with *all Memoirs and Copies or Abstracts of Memoirs furnished by Authors, are to be forwarded, at the close of the Sectional Meetings*, to the Secretary.

The Vice-Presidents and Secretaries of Sections become *ex officio* temporary Members of the General Committee (*vide* p. xxix), and will receive, on application to the Treasurer in the Reception Room, Tickets entitling them to attend its Meetings.

The Committees will take into consideration any suggestions which may be offered by their Members for the advancement of Science. They are specially requested to review the recommendations adopted at preceding Meetings, as published in the volumes of the Association and the communications made to the Sections at this Meeting, for the purposes of selecting definite points of research to which individual or combined exertion may be usefully directed, and branches of knowledge on the state and progress of which Reports are wanted; to name individuals or Committees for the execution of such Reports or researches; and to state whether, and to what degree, these objects may be usefully advanced by the appropriation of the funds of the Association, by application to Government, Philosophical Institutions, or Local Authorities.

In case of appointment of Committees for special objects of Science, it is expedient that *all Members of the Committee should be named, and one of them appointed to act as Secretary, for insuring attention to business.*

Committees have power to add to their number persons whose assistance they may require.

The recommendations adopted by the Committees of Sections are to be registered in the Forms furnished to their Secretaries, and one Copy of each is to be forwarded, without delay, to the Secretary for presentation to the Committee of Recommendations. *Unless this be done, the Recommendations cannot receive the sanction of the Association.*

N.B.—Recommendations which may originate in any one of the Sections must *first be sanctioned by the Committee of that Section* before they

[1] This and the following sentence were added by the General Committee, 1871.

can be referred to the Committee of Recommendations or confirmed by the General Committee.

The Committees of the Sections shall ascertain whether a Report has been made by every Committee appointed at the previous Meeting to whom a sum of money has been granted, and shall report to the Committee of Recommendations in every case where no such Report has been received.[1]

Notices regarding Grants of Money.

Committees and individuals, to whom grants of money have been entrusted by the Association for the prosecution of particular researches in science, are required to present to each following Meeting of the Association a Report of the progress which has been made; and the Individual or the Member first named of a Committee to whom a money grant has been made must (previously to the next Meeting of the Association) forward to the General Secretaries or Treasurer a statement of the sums which have been expended, and the balance which remains disposable on each grant.

Grants of money sanctioned at any one Meeting of the Association expire *a week before* the opening of the ensuing Meeting; nor is the Treasurer authorized, after that date, to allow any claims on account of such grants, unless they be renewed in the original or a modified form by the General Committee.

No Committee shall raise money in the name or under the auspices of the British Association without special permission from the General Committee to do so; and no money so raised shall be expended except in accordance with the rules of the Association.

In each Committee, the Member first named is the only person entitled to call on the Treasurer, Professor A. W. Williamson, University College, London, W.C., for such portion of the sums granted as may from time to time be required.

In grants of money to Committees, the Association does not contemplate the payment of personal expenses to the members.

In all cases where additional grants of money are made for the continuation of Researches at the cost of the Association, the sum named is deemed to include, as a part of the amount, whatever balance may remain unpaid on the former grant for the same object.

All Instruments, Papers, Drawings, and other property of the Association are to be deposited at the Office of the Association, 22 Albemarle Street, Piccadilly, London, W., when not employed in carrying on scientific inquiries for the Association.

Business of the Sections.

The Meeting Room of each Section is opened for conversation from 10 to 11 daily. *The Section Rooms and approaches thereto can be used for no notices, exhibitions, or other purposes than those of the Association.*

At 11 precisely the Chair will be taken,[2] and the reading of communications, in the order previously made public, commenced. At 3 P.M. the Sections will close.

Sections may, by the desire of the Committees, divide themselves into Departments, as often as the number and nature of the communications delivered in may render such divisions desirable.

[1] Passed by the General Committee at Sheffield, 1879.

[2] The meeting on Saturday may begin, if desired by the Committee, at any time not earlier than 10 or later than 11. Passed by the General Committee at Southport, 1883.

A Report presented to the Association, and read to the Section which originally called for it, may be read in another Section, at the request of the Officers of that Section, with the consent of the Author.

Duties of the Doorkeepers.

1.—To remain constantly at the Doors of the Rooms to which they are appointed during the whole time for which they are engaged.
2.—To require of every person desirous of entering the Rooms the exhibition of a Member's, Associate's, or Lady's Ticket, or Reporter's Ticket, signed by the Treasurer, or a Special Ticket signed by the Secretary.
3.—Persons unprovided with any of these Tickets can only be admitted to any particular Room by order of the Secretary in that Room.

No person is exempt from these Rules, except those Officers of the Association whose names are printed in the programme, p. 1.

Duties of the Messengers.

To remain constantly at the Rooms to which they are appointed during the whole time for which they are engaged, except when employed on messages by one of the Officers directing these Rooms.

Committee of Recommendations.

The General Committee shall appoint at each Meeting a Committee, which shall receive and consider the Recommendations of the Sectional Committees, and report to the General Committee the measures which they would advise to be adopted for the advancement of Science.

All Recommendations of Grants of Money, Requests for Special Researches, and Reports on Scientific Subjects shall be submitted to the Committee of Recommendations, and not taken into consideration by the General Committee unless previously recommended by the Committee of Recommendations.

Corresponding Societies.[1]

(1.) Any Society is eligible to be placed on the List of Corresponding Societies of the Association which undertakes local scientific investigations, and publishes notices of the results.

(2.) Applications may be made by any Society to be placed on the List of Corresponding Societies. Application must be addressed to the Secretary on or before the 1st of June preceding the Annual Meeting at which it is intended they should be considered, and must be accompanied by specimens of the publications of the results of the local scientific investigations recently undertaken by the Society.

(3.) A Corresponding Societies Committee shall be annually nominated by the Council and appointed by the General Committee for the purpose of considering these applications, as well as for that of keeping themselves generally informed of the annual work of the Corresponding Societies, and of superintending the preparation of a list of the papers published by them. This Committee shall make an annual report to the General Committee, and shall suggest such additions or changes in the List of Corresponding Societies as they may think desirable.

(4.) Every Corresponding Society shall return each year, on or before the 1st of June, to the Secretary of the Association, a schedule,

[1] Passed by the General Committee, 1884.

properly filled up, which will be issued by the Secretary of the Association, and which will contain a request for such particulars with regard to the Society as may be required for the information of the Corresponding Societies Committee.

(5.) There shall be inserted in the Annual Report of the Association a list, in an abbreviated form, of the papers published by the Corresponding Societies during the past twelve months which contain the results of the local scientific work conducted by them; those papers only being included which refer to subjects coming under the cognizance of one or other of the various Sections of the Association.

(6.) A Corresponding Society shall have the right to nominate any one of its members, who is also a Member of the Association, as its delegate to the Annual Meeting of the Association, who shall be for the time a Member of the General Committee.

Conference of Delegates of Corresponding Societies.

(7.) The Delegates of the various Corresponding Societies shall constitute a Conference, of which the Chairman, Vice-Chairmen, and Secretaries shall be annually nominated by the Council, and appointed by the General Committee, and of which the members of the Corresponding Societies Committee shall be *ex officio* members.

(8.) The Conference of Delegates shall be summoned by the Secretaries to hold one or more meetings during each Annual Meeting of the Association, and shall be empowered to invite any Member or Associate to take part in the meetings.

(9.) The Secretaries of each Section shall be instructed to transmit to the Secretaries of the Conference of Delegates copies of any recommendations forwarded by the Presidents of Sections to the Committee of Recommendations bearing upon matters in which the co-operation of Corresponding Societies is desired; and the Secretaries of the Conference of Delegates shall invite the authors of these recommendations to attend the meetings of the Conference and give verbal explanations of their objects and of the precise way in which they would desire to have them carried into effect.

(10.) It will be the duty of the Delegates to make themselves familiar with the purport of the several recommendations brought before the Conference, in order that they and others who take part in the meetings may be able to bring those recommendations clearly and favourably before their respective Societies. The Conference may also discuss propositions bearing on the promotion of more systematic observation and plans of operation, and of greater uniformity in the mode of publishing results.

Local Committees.

Local Committees shall be formed by the Officers of the Association to assist in making arrangements for the Meetings.

Local Committees shall have the power of adding to their numbers those Members of the Association whose assistance they may desire.

Officers.

A President, two or more Vice-Presidents, one or more Secretaries, and a Treasurer shall be annually appointed by the General Committee.

Council.

In the intervals of the Meetings, the affairs of the Association shall be managed by a Council appointed by the General Committee. The Council may also assemble for the despatch of business during the week of the Meeting.

Papers and Communications.

The Author of any paper or communication shall be at liberty to reserve his right of property therein.

Accounts.

The Accounts of the Association shall be audited annually, by Auditors appointed by the General Committee.

Table showing the Places and Times of Meeting of the British Association, with Presidents, Vice-Presidents, and Local Secretaries, from its Commencement.

Hingston, Esq., M.D., D.C.L., L.R.C.S.E. Thomas Sterry Hunt, Esq., M.A., D.Sc., LL.D., F.R.S.	S. E. Dawson, Esq. R. A. Ramsay, Esq. S. Rivard, Esq. S. C. Stevenson, Esq. Thos. White, Esq., M.P.
The RIGHT HON. SIR LYON PLAYFAIR, K.C.B., M.P., Ph.D., LL.D., F.R.S. L. & E., F.C.S. ABERDEEN, September 9, 1885.	His Grace the Duke of Richmond and Gordon, K.G., D.C.L., Chancellor of the University of Aberdeen The Right Hon. the Earl of Aberdeen, LL.D., Lord-Lieutenant of Aberdeenshire The Right Hon. the Earl of Crawford and Balcarres, M.A., LL.D., F.R.S., F.R.A.S. James Matthews, Esq., Lord Provost of the City of Aberdeen Professor Sir William Thomson, M.A., LL.D., F.R.S. L. & E., F.R.A.S. Alexander Bain, Esq., M.A., LL.D., Rector of the University of Aberdeen The Very Rev. Principal Pirie, D.D., Vice-Chancellor of the University of Aberdeen Professor W. H. Flower, LL.D., F.R.S., F.L.S., Pres. Z.S., F.G.S.,	J. W. Crombie, Esq., M.A. Angus Fraser, Esq., M.A., M.D., F.C.S. Professor G. Pirie, M.A.

Presidents and Secretaries of the Sections of the Association.

Date and Place	Presidents	Secretaries

MATHEMATICAL AND PHYSICAL SCIENCES.

COMMITTEE OF SCIENCES, I.—MATHEMATICS AND GENERAL PHYSICS.

1832. Oxford......	Davies Gilbert, D.C.L., F.R.S.	Rev. H. Coddington.
1833. Cambridge	Sir D. Brewster, F.R.S.	Prof. Forbes.
1834. Edinburgh	Rev. W. Whewell, F.R.S.	Prof. Forbes, Prof. Lloyd.

SECTION A.—MATHEMATICS AND PHYSICS.

1835. Dublin......	Rev. Dr. Robinson	Prof. Sir W. R. Hamilton, Prof. Wheatstone.
1836. Bristol......	Rev. William Whewell, F.R.S.	Prof. Forbes, W. S. Harris, F. W. Jerrard.
1837. Liverpool...	Sir D. Brewster, F.R.S.	W. S. Harris, Rev. Prof. Powell, Prof. Stevelly.
1838. Newcastle	Sir J. F. W. Herschel, Bart., F.R.S.	Rev. Prof. Chevallier, Major Sabine, Prof. Stevelly.
1839. Birmingham	Rev. Prof. Whewell, F.R.S....	J. D. Chance, W. Snow Harris, Prof. Stevelly.
1840. Glasgow ...	Prof. Forbes, F.R.S............	Rev. Dr. Forbes, Prof. Stevelly, Arch. Smith.
1841. Plymouth	Rev. Prof. Lloyd, F.R.S.	Prof. Stevelly.
1842. Manchester	Very Rev. G. Peacock, D.D., F.R.S.	Prof. M'Culloch, Prof. Stevelly, Rev. W. Scoresby.
1843. Cork.........	Prof. M'Culloch, M.R.I.A. ...	J. Nott, Prof. Stevelly.
1844. York.........	The Earl of Rosse, F.R.S. ...	Rev. Wm. Hey, Prof. Stevelly.
1845. Cambridge	The Very Rev. the Dean of Ely.	Rev. H. Goodwin, Prof. Stevelly, G. G. Stokes.
1846. Southampton.	Sir John F. W. Herschel, Bart., F.R.S.	John Drew, Dr. Stevelly, G. G. Stokes.
1847. Oxford......	Rev. Prof. Powell, M.A., F.R.S.	Rev. H. Price, Prof. Stevelly, G. G. Stokes.
1848. Swansea ...	Lord Wrottesley, F.R.S.	Dr. Stevelly, G. G. Stokes.
1849. Birmingham	William Hopkins, F.R.S.......	Prof. Stevelly, G. G. Stokes, W. Ridout Wills.
1850. Edinburgh	Prof. J. D. Forbes, F.R.S., Sec. R.S.E.	W. J. Macquorn Rankine, Prof. Smyth, Prof. Stevelly, Prof. G. G. Stokes.
1851. Ipswich ...	Rev. W. Whewell, D.D., F.R.S.	S. Jackson, W. J. Macquorn Rankine, Prof. Stevelly, Prof. G. G. Stokes.
1852. Belfast......	Prof. W. Thomson, M.A., F.R.S. L. & E.	Prof. Dixon, W. J. Macquorn Rankine, Prof. Stevelly, J. Tyndall.
1853. Hull.........	The Very Rev. the Dean of Ely, F.R.S.	B. Blaydes Haworth, J. D. Sollitt, Prof. Stevelly, J. Welsh.
1854. Liverpool...	Prof. G. G. Stokes, M.A., Sec. R.S.	J. Hartnup, H. G. Puckle, Prof. Stevelly, J. Tyndall, J. Welsh.
1855. Glasgow ...	Rev. Prof. Kelland, M.A., F.R.S. L. & E.	Rev. Dr. Forbes, Prof. D. Gray, Prof. Tyndall.
1856. Cheltenham	Rev. R. Walker, M.A., F.R.S.	C. Brooke, Rev. T. A. Southwood, Prof. Stevelly, Rev. J. C. Turnbull.
1857. Dublin......	Rev. T. R. Robinson, D.D., F.R.S., M.R.I.A.	Prof. Curtis, Prof. Hennessy, P. A. Ninnis, W. J. Macquorn Rankine, Prof. Stevelly.
1858. Leeds	Rev. W. Whewell, D.D., V.P.R.S.	Rev. S. Earnshaw, J. P. Hennessy, Prof. Stevelly, H. J. S. Smith, Prof. Tyndall.

Date and Place	Presidents	Secretaries
1859. Aberdeen...	The Earl of Rosse, M.A., K.P., F.R.S.	J. P. Hennessy, Prof. Maxwell, H. J. S. Smith, Prof. Stevelly.
1860. Oxford......	Rev. B. Price, M.A., F.R.S....	Rev. G. C. Bell, Rev. T. Rennison, Prof. Stevelly.
1861. Manchester	G. B. Airy, M.A., D.C.L., F.R.S.	Prof. R. B. Clifton, Prof. H. J. S. Smith, Prof. Stevelly.
1862. Cambridge	Prof. G. G. Stokes, M.A., F.R.S.	Prof. R. B. Clifton, Prof. H. J. S. Smith, Prof. Stevelly.
1863. Newcastle	Prof. W. J. Macquorn Rankine, C.E., F.R.S.	Rev. N. Ferrers, Prof. Fuller, F. Jenkin, Prof. Stevelly, Rev. C. T. Whitley.
1864. Bath.........	Prof. Cayley, M.A., F.R.S., F.R.A.S.	Prof. Fuller, F. Jenkin, Rev. G. Buckle, Prof. Stevelly.
1865. Birmingham	W. Spottiswoode, M.A., F.R.S., F.R.A.S.	Rev. T. N. Hutchinson, F. Jenkin, G. S. Mathews, Prof. H. J. S. Smith, J. M. Wilson.
1866. Nottingham	Prof. Wheatstone, D.C.L., F.R.S.	Fleeming Jenkin, Prof. H. J. S. Smith, Rev. S. N. Swann.
1867. Dundee ...	Prof. Sir W. Thomson, D.C.L., F.R.S.	Rev. G. Buckle, Prof. G. C. Foster, Prof. Fuller, Prof. Swan.
1868. Norwich ...	Prof. J. Tyndall, LL.D., F.R.S.	Prof. G. C. Foster, Rev. R. Harley, R. B. Hayward.
1869. Exeter......	Prof. J. J. Sylvester, LL.D., F.R.S.	Prof. G. C. Foster, R. B. Hayward, W. K. Clifford.
1870. Liverpool...	J. Clerk Maxwell, M.A., LL.D., F.R.S.	Prof. W. G. Adams, W. K. Clifford, Prof. G. C. Foster, Rev. W. Allen Whitworth.
1871. Edinburgh	Prof. P. G. Tait, F.R.S.E. ...	Prof. W. G. Adams, J. T. Bottomley, Prof. W. K. Clifford, Prof. J. D. Everett, Rev. R. Harley.
1872. Brighton...	W. De La Rue, D.C.L., F.R.S.	Prof. W. K. Clifford, J. W. L. Glaisher, Prof. A. S. Herschel, G. F. Rodwell.
1873. Bradford...	Prof. H. J. S. Smith, F.R.S.	Prof. W. K. Clifford, Prof. Forbes, J. W. L. Glaisher, Prof. A. S. Herschel.
1874. Belfast......	Rev. Prof. J. H. Jellett, M.A., M.R.I.A.	J. W. L. Glaisher, Prof. Herschel, Randal Nixon, J. Perry, G. F. Rodwell.
1875. Bristol......	Prof. Balfour Stewart, M.A., LL.D., F.R.S.	Prof. W. F. Barrett, J. W. L. Glaisher, C. T. Hudson, G. F. Rodwell.
1876. Glasgow ...	Prof. Sir W. Thomson, M.A., D.C.L., F.R.S.	Prof. W. F. Barrett, J. T. Bottomley, Prof. G. Forbes, J. W. L. Glaisher, T. Muir.
1877. Plymouth...	Prof. G. C. Foster, B.A., F.R.S., Pres. Physical Soc.	Prof. W. F. Barrett, J. T. Bottomley, J. W. L. Glaisher, F. G. Landon.
1878. Dublin......	Rev. Prof. Salmon, D.D., D.C.L., F.R.S.	Prof. J. Casey, G. F. Fitzgerald, J. W. L. Glaisher, Dr. O. J. Lodge.
1879. Sheffield ...	George Johnstone Stoney, M.A., F.R.S.	A. H. Allen, J. W. L. Glaisher, Dr. O. J. Lodge, D. MacAlister.
1880. Swansea ...	Prof. W. Grylls Adams, M.A., F.R.S.	W. E. Ayrton, J. W. L. Glaisher, Dr. O. J. Lodge, D. MacAlister.
1881. York.........	Prof. Sir W. Thomson, M.A., LL.D., D.C.L., F.R.S.	Prof. W. E. Ayrton, Prof. O. J. Lodge, D. MacAlister, Rev. W. Routh.
1882. Southampton.	Rt. Hon. Prof. Lord Rayleigh, M.A., F.R.S.	W. M. Hicks, Prof. O. J. Lodge, D. MacAlister, Rev. G. Richardson.
1883. Southport	Prof. O. Henrici, Ph.D., F.R.S.,	W. M. Hicks, Prof. O. J. Lodge, D. MacAlister, Prof. R. C. Rowe.
1884. Montreal ...	Prof. Sir W. Thomson, M.A., LL.D., D.C.L., F.R.S	C. Carpmael, W. M. Hicks, Prof. A. Johnson, Prof. O. J. Lodge, Dr. D. MacAlister.
1885. Aberdeen...	Prof. G. Chrystal, M.A., F.R.S.E.	R. E. Baynes, R. T. Glazebrook, Prof. W. M. Hicks, Prof. W. Ingram.

CHEMICAL SCIENCE.

COMMITTEE OF SCIENCES, II.—CHEMISTRY, MINERALOGY.

Date and Place	Presidents	Secretaries
1832. Oxford......	John Dalton, D.C.L., F.R.S.	James F. W. Johnston.
1833. Cambridge	John Dalton, D.C.L., F.R.S.	Prof. Miller.
1834. Edinburgh	Dr. Hope.........................	Mr. Johnston, Dr Christison.

SECTION B.—CHEMISTRY AND MINERALOGY.

1835. Dublin......	Dr. T. Thomson, F.R.S.	Dr. Apjohn, Prof. Johnston.
1836. Bristol......	Rev. Prof. Cumming	Dr. Apjohn, Dr. C. Henry, W. Herapath.
1837. Liverpool...	Michael Faraday, F.R.S.......	Prof. Johnston, Prof. Miller, Dr. Reynolds.
1838. Newcastle	Rev. William Whewell, F.R.S.	Prof. Miller, H. L. Pattinson, Thomas Richardson.
1839. Birmingham	Prof. T. Graham, F.R.S.	Dr. Golding Bird, Dr. J. B. Melson.
1840. Glasgow ...	Dr. Thomas Thomson, F.R.S.	Dr. R. D. Thomson, Dr. T. Clark, Dr. L. Playfair.
1841. Plymouth...	Dr. Daubeny, F.R.S.	J. Prideaux, Robert Hunt, W. M. Tweedy.
1842. Manchester	John Dalton, D.C.L., F.R.S.	Dr. L. Playfair, R. Hunt, J. Graham.
1843. Cork.........	Prof. Apjohn, M.R.I.A.........	R. Hunt, Dr. Sweeny.
1844. York.........	Prof. T. Graham, F.R.S.	Dr. L. Playfair, E. Solly, T. H. Barker.
1845. Cambridge	Rev. Prof. Cumming	R. Hunt, J. P. Joule, Prof. Miller, E. Solly.
1846. Southampton	Michael Faraday, D.C.L., F.R.S.	Dr. Miller, R. Hunt, W. Randall.
1847. Oxford......	Rev. W. V. Harcourt, M.A., F.R.S.	B. C. Brodie, R. Hunt, Prof. Solly.
1848. Swansea ...	Richard Phillips, F.R.S.	T. H. Henry, R. Hunt, T. Williams.
1849. Birmingham	John Percy, M.D., F.R.S.......	R. Hunt, G. Shaw.
1850. Edinburgh	Dr. Christison, V.P.R.S.E.	Dr. Anderson, R. Hunt, Dr. Wilson.
1851. Ipswich ...	Prof. Thomas Graham, F.R.S.	T. J. Pearsall, W. S. Ward.
1852. Belfast......	Thomas Andrews, M.D., F.R.S.	Dr. Gladstone, Prof. Hodges, Prof. Ronalds.
1853. Hull	Prof. J. F. W. Johnston, M.A., F.R.S.	H. S. Blundell, Prof. R. Hunt, T. J. Pearsall.
1854. Liverpool	Prof. W. A. Miller, M.D., F.R.S.	Dr. Edwards, Dr. Gladstone, Dr. Price.
1855. Glasgow ...	Dr. Lyon Playfair, C.B., F.R.S.	Prof. Frankland, Dr. H. E. Roscoe.
1856. Cheltenham	Prof. B. C. Brodie, F.R.S. ...	J. Horsley, P. J. Worsley, Prof. Voelcker.
1857. Dublin......	Prof. Apjohn, M.D., F.R.S., M.R.I.A.	Dr. Davy, Dr. Gladstone, Prof. Sullivan.
1858. Leeds	Sir J. F. W. Herschel, Bart., D.C.L.	Dr. Gladstone, W. Odling, R. Reynolds.
1859. Aberdeen...	Dr. Lyon Playfair, C.B., F.R.S.	J. S. Brazier, Dr. Gladstone, G. D. Liveing, Dr. Odling.
1860. Oxford......	Prof. B. C. Brodie, F.R.S......	A. Vernon Harcourt, G. D. Liveing, A. B. Northcote.
1861. Manchester	Prof. W. A. Miller, M.D., F.R.S.	A. Vernon Harcourt, G. D. Liveing.
1862. Cambridge	Prof. W. A. Miller, M.D., F.R.S.	H. W. Elphinstone, W. Odling, Prof. Roscoe.
1863. Newcastle	Dr. Alex. W. Williamson, F.R.S.	Prof. Liveing, H. L. Pattinson, J. C. Stevenson.
1864. Bath.........	W. Odling, M.B., F.R.S., F.C.S.	A. V. Harcourt, Prof. Liveing, R. Biggs.
1865. Birmingham	Prof. W. A. Miller, M.D., V.P.R.S.	A. V. Harcourt, H. Adkins, Prof. Wanklyn, A. Winkler Wills.

Date and Place	Presidents	Secretaries
1866. Nottingham	H. Bence Jones, M.D., F.R.S.	J. H. Atherton, Prof. Liveing, W. J. Russell, J. White.
1867. Dundee ...	Prof. T. Anderson, M.D., F.R.S.E.	A. Crum Brown, Prof. G. D. Liveing, W. J. Russell.
1868. Norwich ...	Prof. E. Frankland, F.R.S., F.C.S.	Dr. A. Crum Brown, Dr. W. J. Russell, F. Sutton.
1869. Exeter	Dr. H. Debus, F.R.S., F.C.S.	Prof. A. Crum Brown, Dr. W. J. Russell, Dr. Atkinson.
1870. Liverpool...	Prof. H. E. Roscoe, B.A., F.R.S., F.C.S.	Prof. A. Crum Brown, A. E. Fletcher, Dr. W. J. Russell.
1871. Edinburgh	Prof. T. Andrews, M.D., F.R.S.	J. T. Buchanan, W. N. Hartley, T. E. Thorpe.
1872. Brighton ...	Dr. J. H. Gladstone, F.R.S....	Dr. Mills, W. Chandler Roberts, Dr. W. J. Russell, Dr. T. Wood.
1873. Bradford ...	Prof. W. J. Russell, F.R.S....	Dr. Armstrong, Dr. Mills, W. Chandler Roberts, Dr. Thorpe.
1874. Belfast......	Prof. A. Crum Brown, M.D., F.R.S.E., F.C.S.	Dr. T. Cranstoun Charles, W. Chandler Roberts, Prof. Thorpe.
1875. Bristol	A. G. Vernon Harcourt, M.A., F.R.S., F.C.S.	Dr. H. E. Armstrong, W. Chandler Roberts, W. A. Tilden.
1876. Glasgow ...	W. H. Perkin, F.R.S.	W. Dittmar, W. Chandler Roberts, J. M. Thomson, W. A. Tilden.
1877. Plymouth...	F. A. Abel, F.R.S., F.C.S. ...	Dr. Oxland, W. Chandler Roberts, J. M. Thomson.
1878. Dublin	Prof. Maxwell Simpson, M.D., F.R.S., F.C.S.	W. Chandler Roberts, J. M. Thomson, Dr. C. R. Tichborne, T. Wills.
1879. Sheffield ...	Prof. Dewar, M.A., F.R.S.	H. S. Bell, W. Chandler Roberts, J. M. Thomson.
1880. Swansea ...	Joseph Henry Gilbert, Ph.D., F.R.S.	H. B. Dixon, Dr. W. R. Eaton Hodgkinson, P. Phillips Bedson, J. M. Thomson.
1881. York.........	Prof. A. W. Williamson, Ph.D., F.R.S.	P. Phillips Bedson, H. B. Dixon, T. Gough.
1882. Southampton.	Prof. G. D. Liveing, M.A., F.R.S.	P. Phillips Bedson, H. B. Dixon, J. L. Notter.
1883. Southport	Dr. J. H. Gladstone, F.R.S...	Prof. P. Phillips Bedson, H. B. Dixon, H. Forster Morley.
1884. Montreal ...	Prof. Sir H. E. Roscoe, Ph.D., LL.D., F.R.S.	Prof. P. Phillips Bedson, H. B. Dixon, T. McFarlane, Prof. W. H. Pike.
1885. Aberdeen ...	Prof. H. E. Armstrong, Ph.D., F.R.S., Sec. C.S.	Prof. P. Phillips Bedson, H. B. Dixon, H. Forster Morley, Dr. W. J. Simpson.

GEOLOGICAL (AND, UNTIL 1851, GEOGRAPHICAL) SCIENCE.

COMMITTEE OF SCIENCES, III.—GEOLOGY AND GEOGRAPHY.

1832. Oxford	R. I. Murchison, F.R.S.	John Taylor.
1833. Cambridge.	G. B. Greenough, F.R.S.	W. Lonsdale, John Phillips.
1834. Edinburgh.	Prof. Jameson	Prof. Phillips, T. Jameson Torrie, Rev. J. Yates.

SECTION C.—GEOLOGY AND GEOGRAPHY.

1835. Dublin	R. J. Griffith	Captain Portlock, T. J. Torrie.
1836. Bristol	Rev. Dr. Buckland, F.R.S.—*Geography*, R. I. Murchison, F.R.S.	William Sanders, S. Stutchbury, T. J. Torrie.
1837. Liverpool...	Rev. Prof. Sedgwick, F.R.S.—*Geography*, G. B. Greenough, F.R.S.	Captain Portlock, R. Hunter.—*Geography*, Captain H. M. Denham, R.N.

Date and Place	Presidents	Secretaries
1838. Newcastle..	C. Lyell, F.R.S., V.P.G.S.—*Geography*, Lord Prudhope.	W. C. Trevelyan, Capt. Portlock.—*Geography*, Capt. Washington.
1839. Birmingham	Rev. Dr. Buckland, F.R.S.—*Geography*, G.B.Greenough, F.R.S.	George Lloyd, M.D., H. E. Strickland, Charles Darwin.
1840. Glasgow ...	Charles Lyell, F.R.S.—*Geography*, G. B. Greenough, F.R.S.	W. J. Hamilton, D. Milne, Hugh Murray, H. E. Strickland, John Scoular, M.D.
1841. Plymouth...	H. T. De la Beche, F.R.S. ...	W. J. Hamilton, Edward Moore, M.D., R. Hutton.
1842. Manchester	R. I. Murchison, F.R.S.	E. W. Binney, R. Hutton, Dr. R. Lloyd, H. E. Strickland.
1843. Cork.........	Richard E. Griffith, F.R.S., M.R.I.A.	Francis M. Jennings, H. E. Strickland.
1844. York.........	Henry Warburton, M.P., Pres. Geol. Soc.	Prof. Ansted, E. H. Bunbury.
1845. Cambridge.	Rev. Prof. Sedgwick, M.A., F.R.S.	Rev. J. C. Cumming, A. C. Ramsay, Rev. W. Thorp.
1846. Southampton.	Leonard Horner, F.R.S.—*Geography*, G. B. Greenough, F.R.S.	Robert A. Austen, Dr. J. H. Norton, Prof. Oldham.—*Geography*, Dr. C. T. Beke.
1847. Oxford......	Very Rev. Dr. Buckland, F.R.S.	Prof. Ansted, Prof. Oldham, A. C. Ramsay, J. Ruskin.
1848. Swansea ...	Sir H. T. De la Beche, C.B., F.R.S.	Starling Benson, Prof. Oldham, Prof. Ramsay.
1849. Birmingham	Sir Charles Lyell, F.R.S., F.G.S.	J. Beete Jukes, Prof. Oldham, Prof. A. C. Ramsay.
1850. Edinburgh[1]	Sir Roderick I. Murchison, F.R.S.	A. Keith Johnston, Hugh Miller, Prof. Nicol.

SECTION C (*continued*).—GEOLOGY.

1851. Ipswich ...	William Hopkins, M.A., F.R.S.	C. J. F. Bunbury, G. W. Ormerod, Searles Wood.
1852. Belfast......	Lieut.-Col. Portlock, R.E., F.R.S.	James Bryce, James MacAdam, Prof. M'Coy, Prof. Nicol.
1853. Hull	Prof. Sedgwick, F.R.S.........	Prof. Harkness, William Lawton.
1854. Liverpool..	Prof. Edward Forbes, F.R.S.	John Cunningham, Prof. Harkness, G. W. Ormerod, J. W. Woodall.
1855. Glasgow ...	Sir R. I. Murchison, F.R.S....	James Bryce, Prof. Harkness, Prof. Nicol.
1856. Cheltenham	Prof. A. C. Ramsay, F.R.S....	Rev. P. B. Brodie, Rev. R. Hepworth, Edward Hull, J. Scougall, T. Wright.
1857. Dublin......	The Lord Talbot de Malahide	Prof. Harkness, Gilbert Sanders, Robert H. Scott.
1858. Leeds	William Hopkins, M.A., LL.D., F.R.S.	Prof. Nicol, H. C. Sorby, E. W. Shaw.
1859. Aberdeen...	Sir Charles Lyell, LL.D., D.C.L., F.R.S.	Prof. Harkness, Rev. J. Longmuir, H. C. Sorby.
1860. Oxford......	Rev. Prof. Sedgwick, LL.D., F.R.S., F.G.S.	Prof. Harkness, Edward Hull, Capt. D. C. L. Woodall.
1861. Manchester	Sir R. I. Murchison, D.C.L., LL.D., F.R.S.	Prof. Harkness, Edward Hull, T. Rupert Jones, G. W. Ormerod.
1862. Cambridge	J. Beete Jukes, M.A., F.R.S.	Lucas Barrett, Prof. T. Rupert Jones, H. C. Sorby.

[1] At a meeting of the General Committee held in 1850, it was resolved 'That the subject of Geography be separated from Geology and combined with Ethnology, to constitute a separate Section, under the title of the "Geographical and Ethnological Section,"' for Presidents and Secretaries of which see page lii.

Date and Place	Presidents	Secretaries
1863. Newcastle	Prof. Warington W. Smyth, F.R.S., F.G.S.	E. F. Boyd, John Daglish, H. C. Sorby, Thomas Sopwith.
1864. Bath.........	Prof. J. Phillips, LL.D., F.R.S., F.G.S.	W. B. Dawkins, J. Johnston, H. C. Sorby, W. Pengelly.
1865. Birmingham	Sir R. I. Murchison, Bart., K.C.B.	Rev. P. B. Brodie, J. Jones, Rev. E. Myers, H. C. Sorby, W. Pengelly.
1866. Nottingham	Prof. A. C. Ramsay, LL.D., F.R.S.	R. Etheridge, W. Pengelly, T. Wilson, G. H. Wright.
1867. Dundee ...	Archibald Geikie, F.R.S., F.G.S.	Edward Hull, W. Pengelly, Henry Woodward.
1868. Norwich ...	R. A. C. Godwin-Austen, F.R.S., F.G.S.	Rev. O. Fisher, Rev. J. Gunn, W. Pengelly, Rev. H. H. Winwood.
1869. Exeter	Prof. R. Harkness, F.R.S., F.G.S.	W. Pengelly, W. Boyd Dawkins, Rev. H. H. Winwood.
1870. Liverpool...	Sir Philip de M. Grey Egerton, Bart., M.P., F.R.S.	W. Pengelly, Rev. H. H. Winwood, W. Boyd Dawkins, G. H. Morton.
1871. Edinburgh	Prof. A. Geikie, F.R.S., F.G.S.	R. Etheridge, J. Geikie, T. McKenny Hughes, L. C. Miall.
1872. Brighton...	R. A. C. Godwin-Austen, F.R.S., F.G.S.	L. C. Miall, George Scott, William Topley, Henry Woodward.
1873. Bradford ...	Prof. J. Phillips, D.C.L., F.R.S., F.G.S.	L. C. Miall, R. H. Tiddeman, W. Topley.
1874. Belfast......	Prof. Hull, M.A., F.R.S., F.G.S.	F. Drew, L. C. Miall, R. G. Symes, R. H. Tiddeman.
1875. Bristol	Dr. Thomas Wright, F.R.S.E., F.G.S.	L. C. Miall, E. B. Tawney, W. Topley.
1876. Glasgow ..	Prof. John Young, M.D.	J. Armstrong, F. W. Rudler, W. Topley.
1877. Plymouth...	W. Pengelly, F.R.S...........	Dr. Le Neve Foster, R. H. Tiddeman, W. Topley.
1878. Dublin......	John Evans, D.C.L., F.R.S., F.S.A., F.G.S.	E. T. Hardman, Prof. J. O'Reilly, R. H. Tiddeman.
1879. Sheffield ...	Prof. P. Martin Duncan, M.B., F.R.S., F.G.S.	W. Topley, G. Blake Walker.
1880. Swansea ...	H. C. Sorby, LL.D., F.R.S., F.G.S.	W. Topley, W. Whitaker.
1881. York.........	A. C. Ramsay, LL.D., F.R.S., F.G.S.	J. E. Clark, W. Keeping, W. Topley, W. Whitaker.
1882. Southampton.	R. Etheridge, F.R.S., F.G.S.	T. W. Shore, W. Topley, E. Westlake, W. Whitaker.
1883. Southport	Prof. W. C. Williamson, LL.D., F.R.S.	R. Betley, C. E. De Rance, W. Topley, W. Whitaker.
1884. Montreal ...	W. T. Blanford, F.R.S., Sec. G.S.	F. Adams, Prof. E. W. Claypole, W. Topley, W. Whitaker.
1885. Aberdeen ...	Prof. J. W. Judd, F.R.S., Sec. G.S.	C. E. De Rance, J. Horne, J. J. H. Teall, W. Topley.

BIOLOGICAL SCIENCES.

COMMITTEE OF SCIENCES, IV.—ZOOLOGY, BOTANY, PHYSIOLOGY, ANATOMY.

1832. Oxford......	Rev. P. B. Duncan, F.G.S. ...	Rev. Prof. J. S. Henslow.
1833. Cambridge[1]	Rev. W. L. P. Garnons, F.L.S.	C. C. Babington, D. Don.
1834. Edinburgh.	Prof. Graham.....................	W. Yarrell, Prof. Burnett.

[1] At this Meeting Physiology and Anatomy were made a separate Committee, for Presidents and Secretaries of which see p. li.

SECTION D.—ZOOLOGY AND BOTANY.

Date and Place	Presidents	Secretaries
1835. Dublin......	Dr. Allman........................	J. Curtis, Dr. Litton.
1836. Bristol......	Rev. Prof. Henslow	J. Curtis, Prof. Don, Dr. Riley, S. Rootsey.
1837. Liverpool...	W. S. MacLeay.................	C. C. Babington, Rev. L. Jenyns, W. Swainson.
1838. Newcastle	Sir W. Jardine, Bart.	J. E. Gray, Prof. Jones, R. Owen, Dr. Richardson.
1839. Birmingham	Prof. Owen, F.R.S.	E. Forbes, W. Ick, R. Patterson.
1840. Glasgow ...	Sir W. J. Hooker, LL.D.......	Prof. W. Couper, E. Forbes, R. Patterson.
1841. Plymouth...	John Richardson, M.D., F.R.S.	J. Couch, Dr. Lankester, R. Patterson.
1842. Manchester	Hon. and Very Rev. W. Herbert, LL.D., F.L.S.	Dr. Lankester, R. Patterson, J. A. Turner.
1843. Cork.........	William Thompson, F.L.S....	G. J. Allman, Dr. Lankester, R. Patterson.
1844. York.........	Very Rev. the Dean of Manchester.	Prof. Allman, H. Goodsir, Dr. King, Dr. Lankester.
1845. Cambridge	Rev. Prof. Henslow, F.L.S....	Dr. Lankester, T. V. Wollaston.
1846. Southampton.	Sir J. Richardson, M.D., F.R.S.	Dr. Lankester, T. V. Wollaston, H. Wooldridge.
1847. Oxford......	H. E. Strickland, M.A., F.R.S.	Dr. Lankester, Dr. Melville, T. V. Wollaston.

SECTION D (*continued*).—ZOOLOGY AND BOTANY, INCLUDING PHYSIOLOGY.

[For the Presidents and Secretaries of the Anatomical and Physiological Subsections and the temporary Section E of Anatomy and Medicine, see p. li.]

1848. Swansea ...	L. W. Dillwyn, F.R.S.........	Dr. R. Wilbraham Falconer, A. Henfrey, Dr. Lankester.
1849. Birmingham	William Spence, F.R.S.	Dr. Lankester, Dr. Russell.
1850. Edinburgh	Prof. Goodsir, F.R.S. L. & E.	Prof. J. H. Bennett, M.D., Dr. Lankester, Dr. Douglas Maclagan.
1851. Ipswich ...	Rev. Prof. Henslow, M.A., F.R.S.	Prof. Allman, F. W. Johnston, Dr. E. Lankester.
1852. Belfast......	W. Ogilby	Dr. Dickie, George C. Hyndman, Dr. Edwin Lankester.
1853. Hull.........	C. C. Babington, M.A., F.R.S.	Robert Harrison, Dr. E. Lankester.
1854. Liverpool...	Prof. Balfour, M.D., F.R.S....	Isaac Byerley, Dr. E. Lankester.
1855. Glasgow ...	Rev. Dr. Fleeming, F.R.S.E.	William Keddie, Dr. Lankester.
1856. Cheltenham	Thomas Bell, F.R.S., Pres.L.S.	Dr. J. Abercrombie, Prof. Buckman, Dr. Lankester.
1857. Dublin......	Prof. W. H. Harvey, M.D., F.R.S.	Prof. J. R. Kinahan, Dr. E. Lankester, Robert Patterson, Dr. W. E. Steele.
1858. Leeds	C. C. Babington, M.A., F.R.S.	Henry Denny, Dr. Heaton, Dr. E. Lankester, Dr. E. Perceval Wright.
1859. Aberdeen...	Sir W. Jardine, Bart., F.R.S.E.	Prof. Dickie, M.D., Dr. E. Lankester, Dr. Ogilvy.
1860. Oxford......	Rev. Prof. Henslow, F.L.S....	W. S. Church, Dr. E. Lankester, P. L. Sclater, Dr. E. Perceval Wright.
1861. Manchester	Prof. C. C. Babington, F.R.S.	Dr. T. Alcock, Dr. E. Lankester, Dr. P. L. Sclater, Dr. E. P. Wright.
1862. Cambridge	Prof. Huxley, F.R.S.	Alfred Newton, Dr. E. P. Wright.
1863. Newcastle	Prof. Balfour, M.D., F.R.S....	Dr. E. Charlton, A. Newton, Rev. H. B. Tristram, Dr. E. P. Wright.
1864. Bath.........	Dr. John E. Gray, F.R.S. ...	H. B. Brady, C. E. Broom, H. T. Stainton, Dr. E. P. Wright.
1865. Birmingham	T. Thomson, M.D., F.R.S. ...	Dr. J. Anthony, Rev. C. Clarke, Rev. H. B. Tristram, Dr. E. P. Wright.

SECTION D (*continued*).—BIOLOGY.[1]

Date and Place	Presidents	Secretaries
1866. Nottingham	Prof. Huxley, LL.D., F.R.S. —*Physiological Dep.*, Prof. Humphry, M.D., F.R.S.—*Anthropological Dep.*, Alf. R. Wallace, F.R.G.S.	Dr. J. Beddard, W. Felkin, Rev. H. B. Tristram, W. Turner, E. B. Tylor, Dr. E. P. Wright.
1867. Dundee ...	Prof. Sharpey, M.D., Sec. R.S. —*Dep. of Zool. and Bot.*, George Busk, M.D., F.R.S.	C. Spence Bate, Dr. S. Cobbold, Dr. M. Foster, H. T. Stainton, Rev. H. B. Tristram, Prof. W. Turner.
1868. Norwich ...	Rev. M. J. Berkeley, F.L.S. —*Dep. of Physiology*, W. H. Flower, F.R.S.	Dr. T. S. Cobbold, G. W. Firth, Dr. M. Foster, Prof. Lawson, H. T. Stainton, Rev. Dr. H. B. Tristram, Dr. E. P. Wright.
1869. Exeter	George Busk, F.R.S., F.L.S. —*Dep. of Bot. and Zool.*, C. Spence Bate, F.R.S.—*Dep. of Ethno.*, E. B. Tylor.	Dr. T. S. Cobbold, Prof. M. Foster, E. Ray Lankester, Prof. Lawson, H. T Stainton, Rev. H. B. Tristram.
1870. Liverpool...	Prof. G. Rolleston, M.A., M.D., F.R.S., F.L.S.—*Dep. of Anat. and Physiol.*, Prof. M. Foster, M.D., F.L.S.—*Dep. of Ethno.*, J. Evans, F.R.S.	Dr. T. S. Cobbold, Sebastian Evans, Prof. Lawson, Thos. J. Moore, H. T. Stainton, Rev. H. B. Tristram, C. Staniland Wake, E. Ray Lankester.
1871. Edinburgh	Prof. Allen Thomson, M.D., F.R.S.—*Dep. of Bot. and Zool.*, Prof. Wyville Thomson, F.R.S.—*Dep. of Anthropol.*, Prof. W. Turner, M.D.	Dr. T. R. Fraser, Dr. Arthur Gamgee, E. Ray Lankester, Prof. Lawson, H. T. Stainton, C. Staniland Wake, Dr. W. Rutherford, Dr. Kelburne King.
1872. Brighton ...	Sir J. Lubbock, Bart., F.R.S.—*Dep. of Anat. and Physiol.*, Dr. Burdon Sanderson, F.R.S.—*Dep. of Anthropol.*, Col. A. Lane Fox, F.G.S.	Prof. Thiselton-Dyer, H. T. Stainton, Prof. Lawson, F. W. Rudler, J. H. Lamprey, Dr. Gamgee, E. Ray Lankester, Dr. Pye-Smith.
1873. Bradford ...	Prof. Allman, F.R.S.—*Dep. of Anat. and Physiol.*, Prof. Rutherford, M.D.—*Dep. of Anthropol.*, Dr. Beddoe, F.R.S.	Prof. Thiselton-Dyer, Prof. Lawson, R. M'Lachlan, Dr. Pye-Smith, E. Ray Lankester, F. W. Rudler, J. H. Lamprey.
1874. Belfast	Prof. Redfern, M.D.—*Dep. of Zool. and Bot.*, Dr. Hooker, C.B., Pres. R.S.—*Dep. of Anthrop.*, Sir W. R. Wilde, M.D.	W. T. Thiselton-Dyer, R. O. Cunningham, Dr. J. J. Charles, Dr. P. H. Pye-Smith, J. J. Murphy, F. W. Rudler.
1875. Bristol	P. L. Sclater, F.R.S.—*Dep. of Anat. and Physiol.*, Prof. Cleland, M.D., F.R.S.—*Dep. of Anthropol.*, Prof. Rolleston, M.D., F.R.S.	E. R. Alston, Dr. McKendrick, Prof. W. R. M'Nab, Dr. Martyn, F. W. Rudler, Dr. P. H. Pye-Smith, Dr. W. Spencer.
1876. Glasgow ...	A. Russel Wallace, F.R.G.S., F.L.S.—*Dep. of Zool. and Bot.*, Prof. A. Newton, M.A., F.R.S.—*Dep. of Anat. and Physiol.*, Dr. J. G. McKendrick, F.R.S.E.	E. R. Alston, Hyde Clarke, Dr. Knox, Prof. W. R. M'Nab, Dr. Muirhead, Prof. Morrison Watson.
1877. Plymouth...	J. Gwyn Jeffreys, LL.D., F.R.S., F.L.S.—*Dep. of Anat. and Physiol.*, Prof. Macalister, M.D.—*Dep. of Anthropol.*, Francis Galton, M.A., F.R.S.	E. R. Alston, F. Brent, Dr. D. J Cunningham, Dr. C. A. Hingston, Prof. W. R. M'Nab, J. B. Rowe, F. W. Rudler.

[1] At a meeting of the General Committee in 1865, it was resolved:—'That the title of Section D be changed to Biology;' and 'That for the word "Subsection," in the rules for conducting the business of the Sections, the word "Department" be substituted.'

Date and Place	Presidents	Secretaries
1878. Dublin	Prof. W. H. Flower, F.R.S.—*Dep. of Anthropol.*, Prof. Huxley, Sec. R.S.—*Dep. of Anat. and Physiol.*, R. McDonnell, M.D., F.R.S.	Dr. R. J. Harvey, Dr. T. Hayden, Prof. W. R. M'Nab, Prof. J. M. Purser, J. B. Rowe, F. W. Rudler.
1879. Sheffield ...	Prof. St. George Mivart, F.R.S.—*Dep. of Anthropol.*, E. B. Tylor, D.C.L., F.R.S. —*Dep. of Anat. and Physiol.*, Dr. Pye-Smith.	Arthur Jackson, Prof. W. R. M'Nab, J. B. Rowe, F. W. Rudler, Prof. Schäfer.
1880. Swansea ...	A. C. L. Günther, M.D., F.R.S. —*Dep. of Anat. and Physiol.*, F. M. Balfour, M.A., F.R.S.—*Dep. of Anthropol.*, F. W. Rudler, F.G.S.	G. W. Bloxam, John Priestley, Howard Saunders, Adam Sedgwick.
1881. York.........	Richard Owen, C.B., M.D., F.R.S.—*Dep. of Anthropol.*, Prof. W. H. Flower, LL.D., F.R.S.—*Dep. of Anat. and Physiol.*, Prof. J. S. Burdon Sanderson, M.D., F.R.S.	G. W. Bloxam, W. A. Forbes, Rev. W. C. Hey, Prof. W. R. M'Nab, W. North, John Priestley, Howard Saunders, H. E. Spencer.
1882. Southampton.	Prof. A. Gamgee, M.D., F.R.S. —*Dep. of Zool. and Bot.*, Prof. M. A. Lawson, M.A., F.L.S.—*Dep. of Anthropol.*, Prof. W. Boyd Dawkins, M.A., F.R.S.	G. W. Bloxam, W. Heape, J. B. Nias, Howard Saunders, A. Sedgwick, T. W. Shore, jun.
1883. Southport [1]	Prof. E. Ray Lankester, M.A., F.R.S.—*Dep. of Anthropol.*, W. Pengelly, F.R.S.	G. W. Bloxam, Dr. G. J. Haslam, W. Heape, W. Hurst, Prof. A. M. Marshall, Howard Saunders, Dr. G. A. Woods.
1884. Montreal [2]...	Prof. H. N. Moseley, M.A., F.R.S.	Prof. W. Osler, Howard Saunders, A. Sedgwick, Prof. R. R. Wright.
1885. Aberdeen ...	Prof. W. C. McIntosh, M.D., LL.D., F.R.S. L. & E.	W. Heape, J. McGregor-Robertson, J. Duncan Matthews, Howard Saunders, H. Marshall Ward.

ANATOMICAL AND PHYSIOLOGICAL SCIENCES.

COMMITTEE OF SCIENCES, V.—ANATOMY AND PHYSIOLOGY.

1833. Cambridge	Dr. Haviland	Dr. Bond, Mr. Paget.
1834. Edinburgh	Dr. Abercrombie	Dr. Roget, Dr. William Thomson.

SECTION E (UNTIL 1847).—ANATOMY AND MEDICINE.

1835. Dublin	Dr. Pritchard......................	Dr. Harrison, Dr. Hart.
1836. Bristol	Dr. Roget, F.R.S.	Dr. Symonds.
1837. Liverpool...	Prof. W. Clark, M.D.	Dr. J. Carson, jun., James Long, Dr. J. R. W. Vose.
1838. Newcastle	T. E. Headlam, M.D.	T. M. Greenhow, Dr. J. R. W. Vose.
1839. Birmingham	John Yelloly, M.D., F.R.S....	Dr. G. O. Rees, F. Ryland.
1840. Glasgow ...	James Watson, M.D.	Dr. J. Brown, Prof. Couper, Prof. Reid.
1841. Plymouth...	P. M. Roget, M.D., Sec. R.S.	Dr. J. Butter, J. Fuge, Dr. R. S Sargent.

[1] By direction of the General Committee at Southampton (1882) the Departments of Zoology and Botany and of Anatomy and Physiology were amalgamated.

[2] By authority of the General Committee, Anthropology was made a separate Section, for Presidents and Secretaries of which see p. lvii.

SECTION E.—PHYSIOLOGY.

Date and Place	Presidents	Secretaries
1842. Manchester	Edward Holme, M.D., F.L.S.	Dr. Chaytor, Dr. R. S. Sargent.
1843. Cork	Sir James Pitcairn, M.D. ...	Dr. John Popham, Dr. R. S. Sargent.
1844 York	J. C. Pritchard, M.D.	I. Erichsen, Dr. R. S. Sargent.
1845. Cambridge	Prof. J. Haviland, M.D.	Dr. R. S. Sargent, Dr. Webster.
1846. Southampton.	Prof. Owen, M.D., F.R.S. ...	C. P. Keele, Dr. Laycock, Dr. Sargent.
1847. Oxford[1] ...	Prof. Ogle, M.D., F.R.S.	Dr. Thomas K. Chambers, W. P. Ormerod.

PHYSIOLOGICAL SUBSECTIONS OF SECTION D.

1850. Edinburgh	Prof. Bennett, M.D., F.R.S.E.	
1855. Glasgow ...	Prof. Allen Thomson, F.R.S.	Prof. J. H. Corbett, Dr. J. Struthers.
1857. Dublin......	Prof. R. Harrison, M.D.	Dr. R. D. Lyons, Prof. Redfern.
1858. Leeds	Sir Benjamin Brodie, Bart., F.R.S.	C. G. Wheelhouse.
1859. Aberdeen...	Prof. Sharpey, M.D., Sec.R.S.	Prof. Bennett, Prof. Redfern.
1860. Oxford......	Prof. G. Rolleston, M.D., F.L.S.	Dr. R. M'Donnell, Dr. Edward Smith.
1861. Manchester	Dr. John Davy, F.R.S.L.& E.	Dr. W. Roberts, Dr. Edward Smith.
1862. Cambridge	G. E. Paget, M.D...............	G. F. Helm, Dr. Edward Smith.
1863. Newcastle	Prof. Rolleston, M.D., F.R.S.	Dr. D. Embleton, Dr. W. Turner.
1864. Bath.........	Dr. Edward Smith, LL.D., F.R.S.	J. S. Bartrum, Dr. W. Turner.
1865. Birmingham.[2]	Prof. Acland, M.D., LL.D., F.R.S.	Dr. A. Fleming, Dr. P. Heslop, Oliver Pembleton, Dr. W. Turner.

GEOGRAPHICAL AND ETHNOLOGICAL SCIENCES.

[For Presidents and Secretaries for Geography previous to 1851, see Section C, p. xlvi.]

ETHNOLOGICAL SUBSECTIONS OF SECTION D.

1846. Southampton	Dr. Pritchard.....................	Dr. King.
1847. Oxford	Prof. H. H. Wilson, M.A. ...	Prof. Buckley.
1848. Swansea ...	....	G. Grant Francis.
1849. Birmingham	....	Dr. R. G. Latham.
1850. Edinburgh	Vice-Admiral Sir A. Malcolm	Daniel Wilson.

SECTION E.—GEOGRAPHY AND ETHNOLOGY.

1851. Ipswich ...	Sir R. I. Murchison, F.R.S., Pres. R.G.S.	R. Cull, Rev. J. W. Donaldson, Dr. Norton Shaw.
1852. Belfast......	Col. Chesney, R.A., D.C.L., F.R.S.	R. Cull, R. MacAdam, Dr. Norton Shaw.
1853. Hull	R. G. Latham, M.D., F.R.S.	R. Cull, Rev. H. W. Kemp, Dr. Norton Shaw.
1854. Liverpool...	Sir R. I. Murchison, D.C.L., F.R.S.	Richard Cull, Rev. H. Higgins, Dr. Ihne, Dr. Norton Shaw.
1855. Glasgow ...	Sir J. Richardson, M.D., F.R.S.	Dr. W. G. Blackie, R. Cull, Dr. Norton Shaw.
1856. Cheltenham	Col. Sir H. C. Rawlinson, K.C.B.	R. Cull, F. D. Hartland, W. H. Rumsey, Dr. Norton Shaw.
1857. Dublin......	Rev. Dr. J. Henthorn Todd, Pres. R.I.A.	R. Cull, S. Ferguson, Dr. R. R. Madden, Dr. Norton Shaw.

[1] By direction of the General Committee at Oxford, Sections D and E were incorporated under the name of 'Section D—Zoology and Botany, including Physiology' (see p. xlix). The Section being then vacant was assigned in 1851 to Geography.

[2] *Vide* note on page l.

Date and Place	Presidents	Secretaries
1858. Leeds	Sir R. I. Murchison, G.C.St.S., F.R.S.	R. Cull, Francis Galton, P. O'Callaghan, Dr. Norton Shaw, Thomas Wright.
1859. Aberdeen...	Rear-Admiral Sir James Clerk Ross, D.C.L., F.R.S.	Richard Cull, Prof. Geddes, Dr. Norton Shaw.
1860. Oxford	Sir R. I. Murchison, D.C.L., F.R.S.	Capt. Burrows, Dr. J. Hunt, Dr. C. Lemprière, Dr. Norton Shaw.
1861. Manchester	John Crawfurd, F.R.S..........	Dr. J. Hunt, J. Kingsley, Dr. Norton Shaw, W. Spottiswoode.
1862. Cambridge	Francis Galton, F.R.S..........	J. W. Clarke, Rev. J. Glover, Dr. Hunt, Dr. Norton Shaw, T. Wright.
1863. Newcastle	Sir R. I. Murchison, K.C.B., F.R.S.	C. Carter Blake, Hume Greenfield, C. R. Markham, R. S. Watson.
1864. Bath.........	Sir R. I. Murchison, K.C.B., F.R.S.	H. W. Bates, C. R. Markham, Capt. R. M. Murchison, T. Wright.
1865. Birmingham	Major-General Sir H. Rawlinson, M.P., K.C.B., F.R.S.	H. W. Bates, S. Evans, G. Jabet, C. R. Markham, Thomas Wright.
1866. Nottingham	Sir Charles Nicholson, Bart., LL.D.	H. W. Bates, Rev. E. T. Cusins, R. H. Major, Clements R. Markham, D. W. Nash, T. Wright.
1867. Dundee ...	Sir Samuel Baker, F.R.G.S.	H. W. Bates, Cyril Graham, Clements R. Markham, S. J. Mackie, R. Sturrock.
1868. Norwich ...	Capt. G. H. Richards, R.N., F.R.S.	T. Baines, H. W. Bates, Clements R. Markham, T. Wright.

SECTION E (*continued*).—GEOGRAPHY.

Date and Place	Presidents	Secretaries
1869. Exeter	Sir Bartle Frere, K.C.B., LL.D., F.R.G.S.	H. W. Bates, Clements R. Markham, J. H. Thomas.
1870. Liverpool...	Sir R. I. Murchison, Bt., K.C.B., LL.D., D.C.L., F.R.S., F.G.S.	H. W. Bates, David Buxton, Albert J. Mott, Clements R. Markham.
1871. Edinburgh	Colonel Yule, C.B., F.R.G.S.	Clements R. Markham, A. Buchan, J. H. Thomas, A. Keith Johnston.
1872. Brighton ...	Francis Galton, F.R.S..........	H. W. Bates, A. Keith Johnston, Rev. J. Newton, J. H. Thomas.
1873. Bradford ...	Sir Rutherford Alcock, K.C.B.	H. W. Bates, A. Keith Johnston, Clements R. Markham.
1874. Belfast......	Major Wilson, R.E., F.R.S., F.R.G.S.	E. G. Ravenstein, E. C. Rye, J. H. Thomas.
1875. Bristol	Lieut.-General Strachey, R.E., C.S.I., F.R.S., F.R.G.S., F.L.S., F.G.S.	H. W. Bates, E. C. Rye, F. F. Tuckett.
1876. Glasgow ...	Capt. Evans, C.B., F.R.S.......	H. W. Bates, E. C. Rye, R. Oliphant Wood.
1877. Plymouth...	Adm. Sir E. Ommanney, C.B., F.R.S., F.R.G.S., F.R.A.S.	H. W. Bates, F. E. Fox, E. C. Rye.
1878. Dublin......	Prof. Sir C. Wyville Thomson, LL.D., F.R.S.L.&E.	John Coles, E. C. Rye.
1879. Sheffield ...	Clements R. Markham, C.B., F.R.S., Sec. R.G.S.	H. W. Bates, C. E. D. Black, E. C. Rye.
1880. Swansea ...	Lieut.-Gen. Sir J. H. Lefroy, C.B., K.C.M.G., R.A., F.R.S., F.R.G.S.	H. W. Bates, E. C. Rye.
1881. York.........	Sir J. D. Hooker, K.C.S.I., C.B., F.R.S.	J. W. Barry, H. W. Bates.
1882. Southampton.	Sir R. Temple, Bart., G.C.S.I., F.R.G.S.	E. G. Ravenstein, E. C. Rye.

Date and Place	Presidents	Secretaries
1883. Southport	Lieut.-Col. H. H. Godwin-Austen, F.R.S.	John Coles, E. G. Ravenstein, E. C. Rye.
1884. Montreal ...	Gen. Sir J. H. Lefroy, C.B., K.C.M.G., F.R.S., V.P.R.G.S.	Rev. Abbé Laflamme, J. S. O'Halloran, E. G. Ravenstein, J. F. Torrance
1885. Aberdeen...	Gen. J. T. Walker, C.B., R.E., LL.D., F.R.S.	J. S. Keltie, J. S. O'Halloran, E. G. Ravenstein, Rev. G. A. Smith.

STATISTICAL SCIENCE.

COMMITTEE OF SCIENCES, VI.—STATISTICS.

1833. Cambridge	Prof. Babbage, F.R.S.	J. E. Drinkwater.
1834. Edinburgh	Sir Charles Lemon, Bart.......	Dr. Cleland, C. Hope Maclean.

SECTION F.—STATISTICS.

1835. Dublin	Charles Babbage, F.R.S.	W. Greg, Prof. Longfield.
1836. Bristol	Sir Chas. Lemon, Bart., F.R.S.	Rev. J. E. Bromby, C. B. Fripp, James Heywood.
1837. Liverpool...	Rt. Hon. Lord Sandon	W. R. Greg, W. Langton, Dr. W. C. Tayler.
1838. Newcastle	Colonel Sykes, F.R.S.	W. Cargill, J. Heywood, W. R. Wood.
1839. Birmingham	Henry Hallam, F.R.S.	F. Clarke, R. W. Rawson, Dr. W. C. Tayler.
1840. Glasgow ...	Rt. Hon. Lord Sandon, M.P., F.R.S.	C. R. Baird, Prof. Ramsay, R. W. Rawson.
1841 Plymouth...	Lieut.-Col. Sykes, F.R.S.......	Rev. Dr. Byrth, Rev. R. Luney, R. W. Rawson.
1842. Manchester	G. W. Wood, M.P., F.L.S. ...	Rev. R. Luney, G. W. Ormerod, Dr. W. C. Tayler.
1843. Cork	Sir C. Lemon, Bart., M.P. ...	Dr. D. Bullen, Dr. W. Cooke Tayler.
1844. York.........	Lieut.-Col. Sykes, F.R.S., F.L.S.	J. Fletcher, J. Heywood, Dr. Laycock.
1845. Cambridge	Rt. Hon. the Earl Fitzwilliam	J. Fletcher, Dr. W. Cooke Tayler.
1846. Southampton.	G. R. Porter, F.R.S.	J. Fletcher, F. G. P. Neison, Dr. W. C. Tayler, Rev. T. L. Shapcott.
1847. Oxford	Travers Twiss, D.C.L., F.R.S.	Rev. W. H. Cox, J. J. Danson, F. G. P. Neison.
1848. Swansea ...	J. H. Vivian, M.P., F.R.S. ...	J. Fletcher, Capt. R. Shortrede.
1849. Birmingham	Rt. Hon. Lord Lyttelton......	Dr. Finch, Prof. Hancock, F. G. P. Neison.
1850. Edinburgh	Very Rev. Dr. John Lee, V.P.R.S.E.	Prof. Hancock, J. Fletcher, Dr. J. Stark.
1851. Ipswich ...	Sir John P. Boileau, Bart. ...	J. Fletcher, Prof. Hancock.
1852. Belfast......	His Grace the Archbishop of Dublin.	Prof. Hancock, Prof. Ingram, James MacAdam, jun.
1853. Hull	James Heywood, M.P., F.R.S.	Edward Cheshire, W. Newmarch.
1854. Liverpool...	Thomas Tooke, F.R.S.	E. Cheshire, J. T. Danson, Dr. W. H. Duncan, W. Newmarch.
1855. Glasgow ...	R. Monckton Milnes, M.P. ...	J. A. Campbell, E. Cheshire, W. Newmarch, Prof. R. H. Walsh.

SECTION F (*continued*).—ECONOMIC SCIENCE AND STATISTICS.

1856. Cheltenham	Rt. Hon. Lord Stanley, M.P.	Rev. C. H. Bromby, E. Cheshire, Dr W. N. Hancock, W. Newmarch, W. M. Tartt.
1857. Dublin	His Grace the Archbishop of Dublin, M.R.I.A.	Prof. Cairns, Dr. H. D. Hutton, W. Newmarch.

Date and Place	Presidents	Secretaries
1858. Leeds	Edward Baines	T. B. Baines, Prof. Cairns, S. Brown, Capt. Fishbourne, Dr. J. Strang.
1859. Aberdeen...	Col. Sykes, M.P., F.R.S.	Prof. Cairns, Edmund Macrory, A. M. Smith, Dr. John Strang.
1860. Oxford......	Nassau W. Senior, M.A.	Edmund Macrory, W. Newmarch, Rev. Prof. J. E. T. Rogers.
1861. Manchester	William Newmarch, F.R.S....	David Chadwick, Prof. R. C. Christie, E. Macrory, Rev. Prof. J. E. T. Rogers.
1862. Cambridge	Edwin Chadwick, C.B.	H. D. Macleod, Edmund Macrory.
1863. Newcastle .	William Tite, M.P., F.R.S. ...	T. Doubleday, Edmund Macrory Frederick Purdy, James Potts.
1864. Bath	William Farr, M.D., D.C.L., F.R.S.	E. Macrory, E. T. Payne, F. Purdy.
1865. Birmingham	Rt. Hon. Lord Stanley, LL.D., M.P.	G. J. D. Goodman, G. J. Johnston, E. Macrory.
1866. Nottingham	Prof. J. E. T. Rogers............	R. Birkin, jun., Prof. Leone Levi, E. Macrory.
1867. Dundee	M. E. Grant Duff, M.P.	Prof. Leone Levi, E. Macrory, A. J. Warden.
1868. Norwich	Samuel Brown, Pres. Instit. Actuaries.	Rev. W. C. Davie, Prof. Leone Levi.
1869. Exeter	Rt. Hon. Sir Stafford H. Northcote, Bart., C.B., M.P.	Edmund Macrory, Frederick Purdy, Charles T. D. Acland.
1870. Liverpool...	Prof. W. Stanley Jevons, M.A.	Chas. R. Dudley Baxter, E. Macrory, J. Miles Moss.
1871. Edinburgh	Rt. Hon. Lord Neaves	J. G. Fitch, James Meikle.
1872. Brighton ...	Prof. Henry Fawcett, M.P. ...	J. G. Fitch, Barclay Phillips.
1873. Bradford ...	Rt. Hon. W. E. Forster, M.P.	J. G. Fitch, Swire Smith.
1874. Belfast......	Lord O'Hagan	Prof. Donnell, Frank P. Fellows, Hans MacMordie.
1875. Bristol	James Heywood, M.A., F.R.S., Pres.S.S.	F. P. Fellows, T. G. P. Hallett, E. Macrory.
1876. Glasgow ...	Sir George Campbell, K.C.S.I., M.P.	A. M'Neel Caird, T. G. P. Hallett, Dr. W. Neilson Hancock, Dr. W. Jack.
1877. Plymouth...	Rt. Hon. the Earl Fortescue	W. F. Collier, P. Hallett, J. T. Pim.
1878. Dublin	Prof. J. K. Ingram, LL.D., M.R.I.A.	W. J. Hancock, C. Molloy, J. T. Pim.
1879. Sheffield ...	G. Shaw Lefevre, M.P., Pres. S.S.	Prof. Adamson, R. E. Leader, C. Molloy.
1880. Swansea ...	G. W. Hastings, M.P.	N. A. Humphreys, C. Molloy.
1881. York.........	Rt. Hon. M. E. Grant-Duff, M.A., F.R.S.	C. Molloy, W. W. Morrell, J. F. Moss.
1882. Southampton.	Rt. Hon. G. Sclater-Booth, M.P., F.R.S.	G. Baden-Powell, Prof. H. S. Foxwell, A. Milnes, C. Molloy.
1883. Southport	R. H. Inglis Palgrave, F.R.S.	Rev. W. Cunningham, Prof. H. S. Foxwell, J. N. Keynes, C. Molloy.
1884. Montreal ...	Sir Richard Temple, Bart., G.C.S.I., C.I.E., F.R.G.S.	Prof. H. S. Foxwell, J. S. McLennan, Prof. J. Watson.
1885. Aberdeen...	Prof. H. Sidgwick, LL.D., Litt.D.	Rev. W. Cunningham, Prof. H. S. Foxwell, C. McCombie, J. F. Moss.

MECHANICAL SCIENCE.

SECTION G.—MECHANICAL SCIENCE.

1836. Bristol......	Davies Gilbert, D.C.L., F.R.S.	T. G. Bunt, G. T. Clark, W. West.
1837. Liverpool...	Rev. Dr. Robinson	Charles Vignoles, Thomas Webster.
1838. Newcastle	Charles Babbage, F.R.S.	R. Hawthorn, C. Vignoles, T. Webster.

Date and Place	Presidents	Secretaries
1839. Birmingham	Prof. Willis, F.R.S., and Robt. Stephenson.	W. Carpmael, William Hawkes, T. Webster.
1840. Glasgow	Sir John Robinson	J. Scott Russell, J. Thomson, J. Tod, C. Vignoles.
1841. Plymouth	John Taylor, F.R.S.	Henry Chatfield, Thomas Webster.
1842. Manchester	Rev. Prof. Willis, F.R.S.	J. F. Bateman, J. Scott Russell, J. Thomson, Charles Vignoles.
1843. Cork	Prof. J. Macneill, M.R.I.A. ...	James Thomson, Robert Mallet.
1844. York	John Taylor, F.R.S.	Charles Vignoles, Thomas Webster.
1845. Cambridge	George Rennie, F.R.S..........	Rev. W. T. Kingsley.
1846. Southampton.	Rev. Prof. Willis, M.A., F.R.S.	William Betts, jun., Charles Manby.
1847. Oxford	Rev. Prof. Walker, M.A., F.R.S.	J. Glynn, R. A. Le Mesurier.
1848. Swansea ...	Rev. Prof. Walker, M.A., F.R.S.	R. A. Le Mesurier, W. P. Struvé.
1849. Birmingham	Robert Stephenson, M.P., F.R.S.	Charles Manby, W. P. Marshall.
1850. Edinburgh	Rev. R. Robinson	Dr. Lees, David Stephenson.
1851. Ipswich	William Cubitt, F.R.S..........	John Head, Charles Manby.
1852. Belfast	John Walker, C.E., LL.D., F.R.S.	John F. Bateman, C. B Hancock, Charles Manby, James Thomson.
1853. Hull	William Fairbairn, C.E., F.R.S.	James Oldham, J. Thomson, W. Sykes Ward.
1854. Liverpool...	John Scott Russell, F.R.S. ...	John Grantham, J. Oldham, J. Thomson.
1855. Glasgow ...	W. J. Macquorn Rankine, C.E., F.R.S.	L. Hill, jun., William Ramsay, J. Thomson.
1856. Cheltenham	George Rennie, F.R.S.	C. Atherton, B. Jones, jun., H. M. Jeffery.
1857. Dublin......	Rt. Hon. the Earl of Rosse, F.R.S.	Prof. Downing, W.T. Doyne, A. Tate, James Thomson, Henry Wright.
1858. Leeds	William Fairbairn, F.R.S. ...	J. C. Dennis, J. Dixon, H. Wright.
1859. Aberdeen...	Rev. Prof. Willis, M.A., F.R.S.	R. Abernethy, P. Le Neve Foster, H. Wright.
1860. Oxford	Prof. W. J. Macquorn Rankine, LL.D., F.R.S.	P. Le Neve Foster, Rev. F. Harrison, Henry Wright.
1861. Manchester	J. F. Bateman, C.E., F.R.S....	P. Le Neve Foster, John Robinson, H. Wright.
1862. Cambridge	Wm. Fairbairn, LL.D., F.R.S.	W. M. Fawcett, P. Le Neve Foster.
1863. Newcastle	Rev. Prof. Willis, M.A., F.R.S.	P. Le Neve Foster, P. Westmacott, J. F. Spencer.
1864. Bath	J. Hawkshaw, F.R.S.	P. Le Neve Foster, Robert Pitt.
1865. Birmingham	Sir W. G. Armstrong, LL.D., F.R.S.	P. Le Neve Foster, Henry Lea, W. P. Marshall, Walter May.
1866. Nottingham	Thomas Hawksley, V.P.Inst. C.E., F.G.S.	P. Le Neve Foster, J. F. Iselin, M. O. Tarbotton.
1867. Dundee......	Prof. W. J. Macquorn Rankine, LL.D., F.R.S.	P. Le Neve Foster, John P. Smith, W. W. Urquhart.
1868. Norwich ...	G. P. Bidder, C.E., F.R.G.S.	P. Le Neve Foster, J. F. Iselin, C. Manby, W. Smith.
1869. Exeter	C. W. Siemens, F.R.S.........	P. Le Neve Foster, H. Bauerman.
1870. Liverpool...	Chas. B. Vignoles, C.E., F.R.S.	H. Bauerman, P. Le Neve Foster, T. King, J. N. Shoolbred.
1871. Edinburgh	Prof. Fleeming Jenkin, F.R.S.	H. Bauerman, Alexander Leslie, J. P. Smith.
1872. Brighton ...	F. J. Bramwell, C.E.	H. M. Brunel, P. Le Neve Foster, J. G. Gamble, J. N. Shoolbred.
1873. Bradford ...	W. H. Barlow, F.R.S.	Crawford Barlow, H. Bauerman, E. H. Carbutt, J. C. Hawkshaw, J. N. Shoolbred.
1874. Belfast	Prof. James Thomson, LL.D., C.E., F.R.S.E.	A. T. Atchison, J. N. Shoolbred, John Smyth, jun.

Date and Place	Presidents	Secretaries
1875. Bristol	W. Froude, C.E., M.A., F.R.S.	W. R. Browne, H. M. Brunel, J. G. Gamble, J. N. Shoolbred.
1876. Glasgow ...	C. W. Merrifield, F.R.S.	W. Bottomley, jun., W. J. Millar, J. N. Shoolbred, J. P. Smith.
1877. Plymouth...	Edward Woods, C.E.	A. T. Atchison, Dr. Merrifield, J. N. Shoolbred.
1878. Dublin	Edward Easton, C.E.	A. T. Atchison, R. G. Symes, H. T. Wood.
1879. Sheffield ...	J. Robinson, Pres. Inst. Mech. Eng.	A. T. Atchison, Emerson Bainbridge, H. T. Wood.
1880. Swansea ...	James Abernethy, V.P. Inst. C.E., F.R.S.E.	A. T. Atchison, H. T. Wood.
1881. York.........	Sir W. G. Armstrong, C.B., LL.D., D.C.L., F.R.S.	A. T. Atchison, J. F. Stephenson, H. T. Wood.
1882. Southampton.	John Fowler, C.E., F.G.S. ...	A. T. Atchison, F. Churton, H. T. Wood.
1883. Southport	James Brunlees, F.R.S.E., Pres.Inst.C.E.	A. T. Atchison, E. Rigg, H. T. Wood.
1884. Montreal ...	Sir F. J. Bramwell, F.R.S., V.P.Inst.C.E.	A. T. Atchison, W. B. Dawson, J. Kennedy, H. T. Wood.
1885. Aberdeen...	B. Baker, M.Inst.C.E.	A. T. Atchison, F. G. Ogilvie, E. Rigg, J. N. Shoolbred.

ANTHROPOLOGICAL SCIENCE.

SECTION H.—ANTHROPOLOGY.

1884. Montreal ...	E. B. Tylor, D.C.L., F.R.S. ...	G. W. Bloxam, W. Hurst.
1885. Aberdeen...	Francis Galton, M.A., F.R.S.	G. W. Bloxam, Dr. J. G. Garson, W. Hurst, Dr. A. Macgregor.

LIST OF EVENING LECTURES.

Date and Place	Lecturer	Subject of Discourse
1842. Manchester	Charles Vignoles, F.R.S......	The Principles and Construction of Atmospheric Railways.
	Sir M. I. Brunel	The Thames Tunnel.
	R. I. Murchison..................	The Geology of Russia.
1843. Cork	Prof. Owen, M.D., F.R.S.......	The Dinornis of New Zealand.
	Prof. E. Forbes, F.R.S..........	The Distribution of Animal Life in the Ægean Sea.
	Dr. Robinson......................	The Earl of Rosse's Telescope.
1844. York	Charles Lyell, F.R.S.	Geology of North America.
	Dr. Falconer, F.R.S.............	The Gigantic Tortoise of the Siwalik Hills in India.
1845. Cambridge	G.B.Airy,F.R.S.,Astron.Royal	Progress of Terrestrial Magnetism.
	R. I. Murchison, F.R.S.	Geology of Russia.
1846. Southampton.	Prof. Owen, M.D., F.R.S. ...	Fossil Mammalia of the British Isles.
	Charles Lyell, F.R.S.	Valley and Delta of the Mississippi.
	W. R. Grove, F.R.S.............	Properties of the Explosive substance discovered by Dr. Schönbein; also some Researches of his own on the Decomposition of Water by Heat.
1847. Oxford......	Rev. Prof. B. Powell, F.R.S.	Shooting Stars.
	Prof. M. Faraday, F.R.S.......	Magnetic and Diamagnetic Phenomena.
	Hugh E. Strickland, F.G.S....	The Dodo (*Didus ineptus*).

Date and Place	Lecturer	Subject of Discourse
1848. Swansea ...	John Percy, M.D., F.R.S.......	Metallurgical Operations of Swansea and its neighbourhood.
	W. Carpenter, M.D., F.R.S....	Recent Microscopical Discoveries.
1849. Birmingham	Dr. Faraday, F.R.S.	Mr. Gassiot's Battery.
	Rev. Prof. Willis, M.A., F.R.S.	Transit of different Weights with varying velocities on Railways.
1850. Edinburgh	Prof. J. H. Bennett, M.D., F.R.S.E.	Passage of the Blood through the minute vessels of Animals in connexion with Nutrition.
	Dr. Mantell, F.R.S.	Extinct Birds of New Zealand.
1851. Ipswich ...	Prof. R. Owen, M.D., F.R.S.	Distinction between Plants and Animals, and their changes of Form.
	G.B. Airy, F.R.S., Astron. Royal	Total Solar Eclipse of July 28, 1851.
1852. Belfast......	Prof. G. G. Stokes, D.C.L., F.R.S.	Recent discoveries in the properties of Light.
	Colonel Portlock, R.E., F.R.S.	Recent discovery of Rock-salt at Carrickfergus, and geological and practical considerations connected with it.
1853. Hull	Prof. J. Phillips, LL.D., F.R.S., F.G.S.	Some peculiar Phenomena in the Geology and Physical Geography of Yorkshire.
	Robert Hunt, F.R.S.............	The present state of Photography.
1854. Liverpool...	Prof. R. Owen, M.D., F.R.S.	Anthropomorphous Apes.
	Col. E. Sabine, V.P.R.S.	Progress of researches in Terrestrial Magnetism.
1855. Glasgow ...	Dr. W. B. Carpenter, F.R.S.	Characters of Species.
	Lieut.-Col. H. Rawlinson ...	Assyrian and Babylonian Antiquities and Ethnology.
1856. Cheltenham	Col. Sir H. Rawlinson	Recent Discoveries in Assyria and Babylonia, with the results of Cuneiform research up to the present time.
	W. R. Grove, F.R.S............	Correlation of Physical Forces.
1857. Dublin......	Prof. W. Thomson, F.R.S. ...	The Atlantic Telegraph.
	Rev. Dr. Livingstone, D.C.L.	Recent Discoveries in Africa.
1858. Leeds	Prof. J. Phillips, LL.D., F.R.S.	The Ironstones of Yorkshire.
	Prof. R. Owen, M.D., F.R.S.	The Fossil Mammalia of Australia.
1859. Aberdeen...	Sir R. I. Murchison, D.C.L....	Geology of the Northern Highlands.
	Rev. Dr. Robinson, F.R.S. ...	Electrical Discharges in highly rarefied Media.
1860. Oxford......	Rev. Prof. Walker, F.R.S. ...	Physical Constitution of the Sun.
	Captain Sherard Osborn, R.N.	Arctic Discovery.
1861. Manchester	Prof. W. A. Miller, M.A., F.R.S.	Spectrum Analysis.
	G.B. Airy, F.R.S., Astron. Royal	The late Eclipse of the Sun.
1862. Cambridge	Prof. Tyndall, LL.D., F.R.S.	The Forms and Action of Water.
	Prof. Odling, F.R.S............	Organic Chemistry.
1863. Newcastle	Prof. Williamson, F.R.S.......	The Chemistry of the Galvanic Battery considered in relation to Dynamics.
	James Glaisher, F.R.S.........	The Balloon Ascents made for the British Association.
1864. Bath.........	Prof. Roscoe, F.R.S............	The Chemical Action of Light.
	Dr. Livingstone, F.R.S.	Recent Travels in Africa.
1865. Birmingham	J. Beete Jukes, F.R.S..........	Probabilities as to the position and extent of the Coal-measures beneath the red rocks of the Midland Counties.
1866. Nottingham	William Huggins, F.R.S. ...	The results of Spectrum Analysis applied to Heavenly Bodies.
	Dr. J. D. Hooker, F.R.S.......	Insular Floras.

Date and Place	Lecturer	Subject of Discourse
1867. Dundee......	Archibald Geikie, F.R.S.......	The Geological Origin of the present Scenery of Scotland.
	Alexander Herschel, F.R.A.S.	The present state of knowledge regarding Meteors and Meteorites.
1868. Norwich ...	J. Fergusson, F.R.S............	Archæology of the early Buddhist Monuments.
	Dr. W. Odling, F.R.S.	Reverse Chemical Actions.
1869. Exeter	Prof. J. Phillips, LL.D., F.R.S.	Vesuvius.
	J. Norman Lockyer, F.R.S....	The Physical Constitution of the Stars and Nebulæ.
1870. Liverpool...	Prof. J. Tyndall, LL.D., F.R.S.	The Scientific Use of the Imagination.
	Prof. W. J. Macquorn Rankine, LL.D., F.R.S.	Stream-lines and Waves, in connection with Naval Architecture.
1871. Edinburgh	F. A. Abel, F.R.S...............	Some recent investigations and applications of Explosive Agents.
	E. B. Tylor, F.R.S.	The Relation of Primitive to Modern Civilization.
1872. Brighton ...	Prof. P. Martin Duncan, M.B., F.R.S.	Insect Metamorphosis.
	Prof. W. K. Clifford	The Aims and Instruments of Scientific Thought.
1873. Bradford ...	Prof. W. C. Williamson, F.R.S.	Coal and Coal Plants.
	Prof. Clerk Maxwell, F.R.S.	Molecules.
1874. Belfast	Sir John Lubbock, Bart., M.P., F.R.S.	Common Wild Flowers considered in relation to Insects.
	Prof. Huxley, F.R.S.	The Hypothesis that Animals are Automata, and its History.
1875. Bristol	W. Spottiswoode, LL.D., F.R.S.	The Colours of Polarized Light.
	F. J. Bramwell, F.R.S..........	Railway Safety Appliances.
1876. Glasgow ...	Prof. Tait, F.R.S.E.	Force.
	Sir Wyville Thomson, F.R.S.	The *Challenger* Expedition.
1877. Plymouth...	W. Warington Smyth, M.A., F.R.S.	The Physical Phenomena connected with the Mines of Cornwall and Devon.
	Prof. Odling, F.R.S............	The new Element, Gallium.
1878. Dublin	G. J. Romanes, F.L.S.	Animal Intelligence.
	Prof. Dewar, F.R.S.	Dissociation, or Modern Ideas of Chemical Action.
1879. Sheffield ...	W. Crookes, F.R.S.	Radiant Matter.
	Prof. E. Ray Lankester, F.R.S.	Degeneration.
1880. Swansea ...	Prof. W. Boyd Dawkins, F.R.S.	Primeval Man.
	Francis Galton, F.R.S..........	Mental Imagery.
1881. York.........	Prof. Huxley, Sec. R.S.	The Rise and Progress of Palæontology.
	W. Spottiswoode, Pres. R.S.	The Electric Discharge, its Forms and its Functions.
1882. Southampton.	Prof. Sir Wm. Thomson, F.R.S.	Tides.
	Prof. H. N. Moseley, F.R.S.	Pelagic Life.
1883. Southport	Prof. R. S. Ball, F.R.S.	Recent Researches on the Distance of the Sun.
	Prof. J. G. McKendrick, F.R.S.E.	Galvani and Animal Electricity.
1884. Montreal...	Prof. O. J. Lodge, D.Sc.	Dust.
	Rev. W. H. Dallinger, F.R.S.	The Modern Microscope in Researches on the Least and Lowest Forms of Life.
1885. Aberdeen...	Prof. W. G. Adams, F.R.S. ...	The Electric Light and Atmospheric Absorption.
	John Murray, F.R.S.E..........	The Great Ocean Basins.

LECTURES TO THE OPERATIVE CLASSES.

Date and Place	Lecturer	Subject of Discourse
1867. Dundee......	Prof. J. Tyndall, LL.D., F.R.S.	Matter and Force.
1868. Norwich ...	Prof. Huxley, LL.D., F.R.S.	A Piece of Chalk.
1869. Exeter	Prof. Miller, M.D., F.R.S. ...	Experimental illustrations of the modes of detecting the Composition of the Sun and other Heavenly Bodies by the Spectrum.
1870. Liverpool...	Sir John Lubbock, Bart., M.P., F.R.S.	Savages.
1872. Brighton ...	W. Spottiswoode, LL.D., F.R.S.	Sunshine, Sea, and Sky.
1873. Bradford ...	C. W. Siemens, D.C.L., F.R.S.	Fuel.
1874. Belfast	Prof. Odling, F.R.S............	The Discovery of Oxygen.
1875. Bristol	Dr. W. B. Carpenter, F.R.S.	A Piece of Limestone.
1876. Glasgow ...	Commander Cameron, C.B., R.N.	A Journey through Africa.
1877. Plymouth...	W. H. Preece.....................	Telegraphy and the Telephone.
1879. Sheffield ...	W. E. Ayrton	Electricity as a Motive Power.
1880. Swansea ...	H. Seebohm, F.Z.S.	The North-East Passage.
1881. York	Prof. Osborne Reynolds, F.R.S.	Raindrops, Hailstones, and Snowflakes.
1882. Southampton.	John Evans, D.C.L. Treas. R.S.	Unwritten History, and how to read it.
1883. Southport	Sir F. J. Bramwell, F.R.S. ...	Talking by Electricity—Telephones.
1884. Montreal ...	Prof. R. S. Ball, F.R.S.........	Comets.
1885. Aberdeen...	H. B. Dixon, M.A.	The Nature of Explosions.

OFFICERS OF SECTIONAL COMMITTEES PRESENT AT THE ABERDEEN MEETING.

SECTION A.—MATHEMATICAL AND PHYSICAL SCIENCE.

President.—Professor G. Chrystal, M.A., F.R.S.E.

Vice-Presidents.—Professor C. Niven, F.R.S.; Lord Rayleigh, F.R.S.; Professor A. Schuster, F.R.S.; Professor G. G. Stokes, Sec.R.S.; Professor Sir W. Thomson, F.R.S.

Secretaries—R. E. Baynes, M.A.; R. T. Glazebrook, F.R.S.; Professor W. M. Hicks, F.R.S. (*Recorder*); Professor W. Ingram, M.A.

SECTION B.—CHEMICAL SCIENCE.

President.—Professor H. E. Armstrong, Ph.D., F.R.S., Sec.C.S.

Vice-Presidents.—Professor Brazier, F.C.S.; Professor A. Crum Brown, F.R.S.; Professor Hartley, F.R.S.; Professor H. McLeod, F.R.S.; Professor W. A. Tilden, F.R.S.

Secretaries.—Professor P. Phillips Bedson, D.Sc. (*Recorder*); H. B. Dixon, M.A.; H. Forster Morley, D.Sc.; W. J. Simpson, M.D.

SECTION C.—GEOLOGY.

President.—Professor J. W. Judd, F.R.S., Sec.G.S.

Vice-Presidents.—John Evans, Treas.R.S.; Rev. George Gordon, LL.D.; T. F. Jamieson, LL.D.; Rev. J. M. Joass, LL.D.; Professor O. C. Marsh, M.A.; Professor W. C. Williamson, F.R.S.

Secretaries.—C. E. De Rance, F.G.S.; J. Horne, F.R.S.E.; J. J. H. Teall, F.G.S.; W. Topley, F.G.S. (*Recorder*).

SECTION D.—BIOLOGY.

President.—Professor W. C. McIntosh, M.D., LL.D., F.R.S. L. and E., F.L.S.

Vice-Presidents.—Professor C. C. Babington, F.R.S.; Professor I. Bayley Balfour, F.R.S.; Professor Cleland, F.R.S.; Sir John Lubbock, Bart., F.R.S.; Professor J. S. Burdon Sanderson, F.R.S.; Professor W. Stirling, F.R.S.E.; Professor Trail, F.L.S.

Secretaries.—W. Heape; J. McGregor-Robertson, M.B.; J. Duncan Matthews, F.R.S.E.; Howard Saunders, F.L.S. (*Recorder*); H. Marshall Ward, M.A.

SECTION E.—GEOGRAPHY.

President.—General J. T. Walker, C.B., R.E., LL.D., F.R.S.

Vice-Presidents.—Professor James Donaldson, F.R.S.E.; Admiral Sir E. Ommanney, C.B., F.R.S.; Lieut.-Colonel R. L. Playfair; Dr. John Rae, F.R.S.

Secretaries.—J. S. Keltie; J. S. O'Halloran, F.R.G.S.; E. G. Ravenstein, F.R.G.S. (*Recorder*); Rev. G. A. Smith, M.A.

SECTION F.—ECONOMIC SCIENCE AND STATISTICS.

President.—Professor Henry Sidgwick, LL.D., Litt.D.

Vice-Presidents.—Professor Adamson, LL.D.; Dr. Alexander Bain; Major P. G. Craigie; Sir Richard Temple, Bart., G.C.S.I.

Secretaries.—Rev. W. Cunningham, B.D.; Professor H. S. Foxwell, M.A. (*Recorder*); C. McCombie; J. F. Moss.

SECTION G.—MECHANICAL SCIENCE.

President.—Benjamin Baker, M.Inst.C.E.

Vice-Presidents.—W. H. Barlow, F.R.S.; Sir James N. Douglass; Professor James Thomson, F.R.S.; Professor W. C. Unwin.

Secretaries.—A. T. Atchison, M.A.; F. G. Ogilvie, M.A., B.Sc.; E. Rigg, M.A. (*Recorder*); J. N. Shoolbred, B.A.

SECTION H.—ANTHROPOLOGY.

President.—Francis Galton, M.A., F.R.S., President of the Anthropological Institute.

Vice-Presidents.—Dr. Alexander Bain; Professor D. J. Cunningham, M.D.; Professor Flower, F.R.S.; W. Pengelly, F.R.S.; Professor Struthers, M.D.; Professor W. Turner, F.R.S.

Secretaries.—G. W. Bloxam, F.L.S. (*Recorder*); J. G. Garson, M.D.; Walter Hurst, B.Sc.; A. McGregor, M.D.

THE GENERAL TREASURER'S ACCOUNT (not including receipts at the Aberdeen Meeting).

REPORT OF THE COUNCIL.

Report of the Council for the year 1884–85, *presented to the General Committee at Aberdeen, on Wednesday, September* 9, 1885.

The Council have received reports during the past year from the General Treasurer, and his accounts for the year will be laid before the General Committee this day.

Since the Meeting at Montreal, the following have been elected Corresponding Members of the Association:—

Bowditch, Prof. H. P.
Brush, Prof. G. J.
Gibbs, Prof. J. Willard.
Gibbs, Prof. Wolcott.
Greely, Lieut. A. W.
Jackson, Prof. C. Loring.
Kikuchi, Prof. Dairoku.
Michelson, A. A.
Newcomb, Prof. Simon.
Powell, Major J. W.
Ray, Captain P. H.
Thurston, Prof. R. H.

The Council have nominated Professor Struthers, M.D., LL.D., to be a Vice-President at the Meeting at Aberdeen.

Soon after the commencement of the present year, Professor Bonney, the Secretary, informed the Council that a considerable increase in the endowment of his Professorship at University College would demand that in future a larger share of his time should be devoted to teaching. As unfortunately the state of his health for some months past had pointed to the need of diminishing rather than increasing his work, he regretted that he would be unable to offer himself for re-election at the present Meeting. The Council received this announcement with very great regret. Professor Bonney not only brought to the office of Secretary a leading scientific position, but also combined with this advantage great energy, zeal, and discretion. It was largely due to his powers of organisation and tact that the exceptional and grave difficulties which attended the holding of last year's Meeting at Montreal were surmounted, and it was brought to a successful issue. The Council have nominated Mr. A. T. Atchison, M.A., who for some years past has rendered most efficient assistance as one of the Secretaries of Section G, to the office of Secretary, vacated by Professor Bonney.

During the present year the Council have considered the stipend paid to Mr. Stewardson, the Clerk of the Association, and the amount assigned to the General Treasurer to enable him to obtain such assistance as may be requisite. Mr. Stewardson was engaged in the year 1873 at a salary of 120*l.*, which was subsequently augmented to 130*l.* The Council now recommend that for the present year it be raised to 135*l.*, and be subsequently increased (subject to the usual conditions) by a sum of 5*l.* at the end of each three years till a maximum of 160*l.* be reached; also that the yearly sum assigned to the General Treasurer be increased from 50*l.* to 60*l.*

On meeting again in Great Britain, the Council venture to express to the General Committee their belief that the anticipations of a successful meeting, expressed in the Report presented at Montreal, have been fully justified by the results, and once more give utterance to the gratitude, which must be felt by all who visited Canada, for the liberal hospitality and cordial reception which welcomed them there. It will be long before this visit is forgotten, or the stimulus, which its exceptional circumstances gave to the energy and life of the Association, ceases to be felt. Towards the close of that Meeting the happy idea occurred to several members of the Association that it would be an appropriate memorial of the visit of the British Association to found a Medal at McGill University, to be given annually for proficiency in Applied Science. The idea, once started, was warmly espoused, and a subscription list was opened, with Lord Rayleigh, the President, as Treasurer, and Messrs. W. Topley and H. T. Wood as Secretaries. The result has been that a sum of about 500*l.* will be transmitted to the authorities of the McGill University for investment. This will enable them to offer, as an annual prize, a Gold Medal and a sum of money. The first award has already been made. The Council, acting under the powers conferred upon them by the General Committee on Nov. 11, 1884, have instructed Mr. Wyon to prepare, at the cost of the Association, a suitable die for the Medal.

The Council, in virtue of the powers conferred upon them by the General Committee at Montreal, in regard to the report concerning Corresponding Societies, have formed the Corresponding Societies' Committee. The Report of the Committee will be presented, and a conference of Delegates, appointed under the new rules, will be held during the present meeting.

The following resolutions were referred by the General Committee to the Council for consideration and action, if desirable:—

'That the Council of the Association be requested to communicate with the Government of the Dominion of Canada in order (1) to call the attention of the Government to the absence of trustworthy information concerning the tides of the Gulf of St. Lawrence and the adjoining Atlantic coast, and to the dangers which thence arise to the navigation; (2) To urge upon the Government the importance of obtaining accurate and systematic tidal observations, and of tabulating and reducing the results by the scientific methods elaborated by Committees of the Association; and (3) to suggest the immediate establishment of a sufficient series of observing stations on the coast of the Dominion.'

A memorial in accordance with the above resolution was adopted by the Council and forwarded to the Government of the Dominion of Canada. To this a reply was received from the Canadian Minister of Marine, expressing regret that the Dominion Government were unable at the present time to undertake a special survey of the tides and currents in the Gulf of St. Lawrence. The Council, however, are not without hope that the proposed observations may be regarded as deferred rather than as refused.

'That the Council memorialise the Canadian Government as to the urgent necessity of encouraging investigation and publication of reports with respect to the physical characters, languages, social, industrial, and artistic condition of the native tribes of the Dominion.'

A memorial in accordance with the above was also adopted by the Council and forwarded to the Government of the Dominion of Canada.

The receipt of this was acknowledged, and the Council were informed that it would be duly considered by the Dominion Government.

'That the attention of the Council be drawn to the advisability of communicating with the Admiralty for the purpose of urging on them the importance of the employment of the Harmonic Analysis in the Reduction of Admiralty Tidal Observations.'

The above recommendation was duly considered, but the Council, while fully conscious of the importance of the subject, deemed the time inopportune for pressing the matter on the attention of the Admiralty.

'That the Council be requested to examine the feasibility of instituting a scheme for promoting an International Scientific Congress, to meet at intervals in different countries, and to report thereon to the General Committee at the next meeting of the Association.'

This most important question has been very fully considered by the Council during the past year. The importance of such a Congress can hardly be doubted; at the same time there are many serious difficulties in devising a practical scheme, and many considerations to be taken into account, before it would be prudent to undertake so great a departure from the ordinary procedure of the Association, as would be involved by such schemes as have seemed most feasible. The following is a brief history of what has been done: At the conclusion of the Montreal Meeting a Committee of the Council (of which Mr. Vernon Harcourt, the General Secretary, was a member) took the opportunity of being present at the meeting of the American Association at Philadelphia to confer with some members of the Committee in America, from whom the latest and most definite proposal of an International Scientific Association has emanated. After returning to England, a letter was received by Mr. Vernon Harcourt from Dr. S. C. Minot, Secretary to the above Committee, which was laid before a Committee of the Council. As a result of their consideration of this letter, the Secretary entered into an informal correspondence with Dr. C. S. Minot. The intent of this correspondence was to bring about an exchange of views and a discussion of certain difficulties which presented themselves at first sight, and as it, in effect, contains the outline of a scheme, the Council (with Dr. Minot's permission) have resolved to place it, together with extracts from his letter to Mr. Vernon Harcourt, in the hands of the General Committee. Copies of it are accordingly distributed with this Report. The Council, in the next place, deemed it desirable to ascertain what support the proposal of a joint meeting of the British Association and of the International Scientific Association, in the suggested rudimentary form, would meet with from the more important scientific societies in London; for, without their favourable countenance and the permission to use the rooms of such as were conveniently situated, the project would necessarily be abortive. A circular was accordingly addressed to a number of the London scientific societies, with the result that out of 29 societies which sent answers, three expressed their inability, in consequence of formal difficulties, to reply at present; two were opposed to the scheme; five were favourable; and the rest were not hostile. It should, however, be remarked, that while a willingness to lend rooms was very generally shown, any approbation of the scheme was expressed in very guarded terms, and amounted, in the majority of cases, to little more than a non-expression of disapproval. In these circumstances the Council invite the General Committee to take the matter into

their consideration during the Aberdeen Meeting, and suggest that the second meeting of the General Committee would be the most convenient opportunity for a discussion.

One vacancy in the Council has been caused by the lamented death of Dr. Gwyn Jeffreys; another by the resignation of Prof. Prestwich; it follows, therefore, that in accordance with the rule, three other members will retire. The retiring members will be:—

Sir F. J. Evans. Prof. W. G. Adams.
The Right Hon. G. Sclater-Booth.

The Council recommend the re-election of the other ordinary Members of Council, with the addition of the gentlemen whose names are distinguished by an asterisk in the following list:—

Abney, Capt. W. de W., F.R.S.
Ball, Prof. R. S., F.R.S.
Bateman, J. F. La Trobe, Esq., F.R.S.
*Blanford, W. T., Esq., F.R.S.
Bramwell, Sir F. J., F.R.S.
*Crookes, W., Esq., F.R.S.
Dawkins, Prof. W. Boyd, F.R.S.
De La Rue, Dr. Warren, F.R.S.
Dewar, Prof. J., F.R.S.
Flower, Prof. W. H., F.R.S.
Gladstone, Dr. J. H., F.R.S.
Glaisher, J. W. L., Esq., F.R.S.
Godwin-Austen, Lieut.-Col. H. H., F.R.S.
Hawkshaw, J. Clarke, Esq., F.G.S.
Henrici, Prof. O., F.R.S.
Hughes, Prof. T. McK., F.G.S.
*Martin, J. B., Esq., F.S.S.
*M'Leod, Prof. H., F.R.S.
Moseley, Prof. H. N., F.R.S.
Ommanney, Admiral Sir E., C.B., F.R.S.
Pengelly, W., Esq., F.R.S.
Perkin, Dr. W. H., F.R.S.
Sorby, Dr. H. C., F.R.S.
Temple, Sir R., Bart., G.C.S.I.
*Thiselton-Dyer, W. T., Esq., C.M.G., F.R.S.

Recommendations adopted by the General Committee at the Aberdeen Meeting in September 1885.

[When Committees are appointed, the Member first named is regarded as the Secretary, except there is a specific nomination.]

Involving Grants of Money.

That Professor G. Carey Foster, Sir William Thomson, Professor Ayrton, Professor J. Perry, Professor W. G. Adams, Lord Rayleigh, Dr. O. J. Lodge, Dr. John Hopkinson, Dr. A. Muirhead, Mr. W. H. Preece, Mr. Herbert Taylor, Professor Everett, Professor Schuster, Dr. J. A. Fleming, Professor G. F. Fitzgerald, Mr. R. T. Glazebrook, Professor Chrystal, Mr. H. Tomlinson, Professor W. Garnett, Professor J. J. Thomson, and Mr. W. N. Shaw be reappointed a Committee for the purpose of constructing and issuing practical Standards for use in Electrical Measurements; that Mr. Glazebrook be the Secretary, and that the sum of 40*l.* be placed at their disposal for the purpose.

That Professor Balfour Stewart, Professor Schuster, Professor Stokes, Mr. G. Johnstone Stoney, Professor Sir H. E. Roscoe, Captain Abney, and Mr. G. J. Symons be reappointed a Committee for the purpose of considering the best methods of recording the direct intensity of Solar Radiation; that Professor Balfour Stewart be the Secretary, and that the unexpended sum of 20*l.* be placed at their disposal for the purpose.

That Professor Balfour Stewart (Secretary), Mr. Knox Laughton, Mr. G. J. Symons, and Mr. R. H. Scott be reappointed a Committee, with power to add to their number, for the purpose of co-operating with Mr. E. J. Lowe in his project of establishing a Meteorological Observatory near Chepstow on a permanent and scientific basis, and that the unexpended sum of 25*l.* be again placed at their disposal for the purpose.

That Professor G. H. Darwin, Sir W. Thomson, and Major Baird be a Committee for the purpose of preparing instructions for the practical work of Tidal Observation; that Professor Darwin be the Secretary, and that the sum of 50*l.* be placed at their disposal for the purpose.

That Professors Balfour Stewart and Sir W. Thomson, Sir J. H. Lefroy, Sir Frederick Evans, Professor G. H. Darwin, Professor G. Chrystal, Professor S. J. Perry, Mr. C. H. Carpmael, Professor Schuster, Mr. G. M. Whipple, and Captain Creake be reappointed a Committee for the purpose of considering the best means of comparing and reducing Magnetic Observations; that Professor Balfour Stewart be the Secretary, and that the sum of 40*l.* be placed at their disposal for the purpose.

That Professor G. Forbes, Captain Abney, Dr. J. Hopkinson, Professor W. G. Adams, Professor G. C. Foster, Lord Rayleigh, Mr. Preece, Professor Schuster, Professor Dewar, Mr. A. Vernon Harcourt, Professor Ayrton, and Sir James Douglass be reappointed a Committee for the purpose of reporting on Standards of Light; that Professor G. Forbes be the Secretary, and that the sum of 20*l.* be placed at their disposal for the purpose.

That Professor Crum Brown, Mr. Milne-Home, Mr. John Murray, and Mr. Buchan be reappointed a Committee for the purpose of co-operating with the Scottish Meteorological Society in making meteorological observations on Ben Nevis; that Professor Crum Brown be the Secretary, and that the sum of 100*l.* be placed at their disposal for the purpose.

That Professors Armstrong, Lodge, and Sir William Thomson, Lord Rayleigh, Professors Schuster, Poynting, J. J. Thomson, Fitzgerald, Crum Brown, Ramsay, Frankland, Tilden, and Hartley, Captain Abney, Messrs. W. N. Shaw, H. B. Dixon, J. T. Bottomley, W. Crookes, and Shelford Bidwell, and Dr. Fleming be a Committee for the purpose of considering the subject of Electrolysis in its Physical and Chemical bearings; that Professor Armstrong be the Chemical Secretary and Professor Lodge the Physical Secretary, and that the sum of 20*l.* be placed at their disposal for the purpose.

That Professors McLeod and Ramsay and Mr. W. A. Shenstone be a Committee for the further investigation of the Influence of the Silent Discharge of Electricity on Oxygen and other gases; that Mr. W. A. Shenstone be the Secretary, and that the sum of 20*l.* be placed at their disposal for the purpose.

That Professors Williamson, Dewar, Frankland, Crum Brown, Odling, and Armstrong, Drs. Hugo Müller, A. G. Vernon Harcourt, F. R. Japp, and H. Forster Morley, and Messrs. C. E. Groves, J. Millar Thomson, V. H. Veley, and H. B. Dixon be reappointed a Committee for the purpose of drawing up a statement of the varieties of Chemical Names which have come into use, for indicating the causes which have led to their adoption, and for considering what can be done to bring about some convergence of the views on Chemical Nomenclature obtaining among English and foreign chemists; that Mr. H. B. Dixon be the Secretary, and that the sum of 5*l.* be placed at their disposal for the purpose.

That Mr. W. T. Blanford, Professor J. W. Judd, and Messrs. W. Carruthers, H. Woodward, and J. S. Gardner be reappointed a Committee for the purpose of reporting on the Fossil Plants of the Tertiary and Secondary Beds of the United Kingdom; that Mr. J. S. Gardner be the Secretary, and that the sum of 20*l.* be placed at their disposal for the purpose.

That Professor T. McK. Hughes, Dr. H. Hicks, Dr. H. Woodward, and Messrs. E. B. Luxmoore, P. Pennant, and Edwin Morgan be a Committee for the purpose of exploring the Caves of North Wales; that Dr. H. Hicks be the Secretary, and that the sum of 25*l.* be placed at their disposal for the purpose.

That Mr. R. Etheridge, Mr. T. Gray, and Professor John Milne be reappointed a Committee for the purpose of investigating the Volcanic Phenomena of Japan; that Professor John Milne be the Secretary, and that the sum of 50*l.* be placed at their disposal for the purpose.

That Messrs. R. B. Grantham, C. E. De Rance, J. B. Redman, W. Topley, W. Whitaker, and J. W. Woodall, Major-General Sir A. Clarke, Admiral Sir E. Ommanney, Sir J. N. Douglass, Captain Sir F. J. O. Evans, Captain J. Parsons, Captain W. J. L. Wharton, Professor J. Prestwich, and Messrs. E. Easton, J. S. Valentine, and L. F. Vernon Harcourt be reappointed a Committee for the purpose of inquiring into the Rate of Erosion of the Sea-coasts of England and Wales, and the Influence of the Artificial Abstraction of Shingle or other Material in that

Action; that Messrs. De Rance and Topley be the Secretaries, and that the sum of 20*l.* be placed at their disposal for the purpose.

That Messrs. H. Bauerman, F. W. Rudler, J. J. H. Teall, and H. J. Johnston-Lavis be reappointed a Committee for the purpose of investigating the Volcanic Phenomena of Vesuvius and its neighbourhood; that Mr. H. J. Johnston-Lavis be the Secretary, and that the sum of 30*l.* be placed at their disposal for the purpose.

That Dr. J. Evans, Professor W. J. Sollas, Dr. G. J. Hinde, and Messrs. W. Carruthers, R. B. Newton, J. J. H. Teall, F. W. Rudler, W. Topley, W. Whitaker, and E. Wethered be a Committee for the purpose of carrying on the Geological Record; that Mr. W. Topley be the Secretary, and that the sum of 100*l.* be placed at their disposal for the purpose.

That Mr. R. Etheridge, Dr. H. Woodward, and Professor T. R. Jones be reappointed a Committee for the purpose of reporting on the Fossil Phyllopoda of the Palæozoic Rocks; that Professor T. R. Jones be the Secretary, and that the sum of 15*l.* be placed at their disposal for the purpose.

That Mr. Stainton, Sir John Lubbock, and Mr. McLachlan be a Committee for the purpose of continuing a Record of Zoological Literature; that Mr. Stainton be the Secretary, and that the sum of 100*l.* be placed at their disposal for the purpose.

That Mr. John Murray, Professor Cossar Ewart, Professor Alleyne Nicholson, Professor McIntosh, Professor Young, Professor Struthers, and Professor McKendrick be reappointed a Committee for the purposes of a Marine Biological Station at Granton, Scotland; that Mr. John Murray be the Secretary, and that the sum of 75*l.* be placed at their disposal for the purpose.

That Professor Ray Lankester, Mr. P. L. Sclater, Professor M. Foster, Mr. A. Sedgwick, Professor A. M. Marshall, Professor A. C. Haddon, Professor Moseley, and Mr. Percy Sladen be reappointed a Committee for the purpose of arranging for the occasional occupation of a table at the Zoological Station at Naples; that Mr. Percy Sladen be the Secretary, and that the sum of 50*l.* be placed at their disposal for the purpose.

That Professor Cleland, Professor McKendrick, Professor Ewart, Professor Stirling, Professor Bower, Dr. Cleghorn, and Professor McIntosh be a Committee for the purpose of continuing the Researches on Food Fishes and Invertebrates at the Marine Laboratory, St. Andrews; that Professor McIntosh be the Secretary, and that the sum of 75*l.* be placed at their disposal for the purpose.

That Mr. J. Cordeaux, Mr. J. A. Harvie-Brown, Professor Newton, Mr. W. Eagle Clarke, Mr. R. M. Barrington, and Mr. A. G. More be appointed a Committee for the purpose of obtaining (with the consent of the Master and Elder Brethren of the Trinity House and the Commissioners of Northern and Irish Lights) observations on Migration at Lighthouses and Lightvessels, and of reporting on the same; that Mr. J. Cordeaux be the Secretary, and that the sum of 30*l.* be placed at their disposal for the purpose.

That Professor Cleland, Professor McKendrick, and Dr. McGregor-Robertson be a Committee for the purpose of investigating the Mechanism of the Secretion of Urine; that Dr. McGregor-Robertson be the Secretary, and that the sum of 10*l.* be placed at their disposal for the purpose.

That General J. T. Walker, Sir J. H. Lefroy, Lieut.-Colonel Godwin-

Austen, Mr. W. T. Blanford, Mr. Sclater, Mr. Carruthers, Mr. Thiselton-Dyer, Professor Struthers, Mr. G. W. Bloxam, Mr. H. W. Bates, Lord Alfred Churchill, Mr. F. Galton, Mr. J. S. O'Halloran, Mr. Coutts Trotter, and Professor Moseley be a Committee for the purpose of furthering the Exploration of New Guinea, by making a grant to Mr. Forbes for the purposes of his Expedition; that Mr. H. W. Bates be the Secretary, and that the sum of 150*l.* be placed at their disposal for the purpose.

That General J. T. Walker, Sir J. H. Lefroy, Sir William Thomson, Mr. Alexander Buchan, Mr. J. Y. Buchanan, Mr. John Murray, Dr. Rae, Mr. H. W. Bates, and Captain W. J. Dawson be a Committee for the purpose of organising a systematic investigation of the Depth of the permanently Frozen Soil in the Polar Regions, its geographical limits, and relation to the present Pole of greatest cold; that Mr. H. W. Bates be the Secretary, and that the sum of 5*l.* be placed at their disposal for the purpose.

That Professor Sidgwick, Professor Foxwell, the Rev. W. Cunningham, and Professor Munro be a Committee for the purpose of inquiring into the Regulation of Wages under the Sliding Scales; that Professor Munro be the Secretary, and that the sum of 10*l.* be placed at their disposal for the purpose.

That Mr. W. H. Barlow, Professor J. Thomson, Captain D. Galton, Mr. B. Baker, Professor W. C. Unwin, Professor A. B. W. Kennedy, Mr. C. Barlow, Mr. A. T. Atchison, and Professor H. S. Hele Shaw be a Committee for the purpose of obtaining information with reference to the Endurance of Metals under repeated and varying stresses, and the proper working stresses on Railway Bridges and other structures subject to varying loads; that Mr. A. T. Atchison be the Secretary, and that the sum of 10*l.* be placed at their disposal for the purpose.

That Dr. Garson, Mr. Pengelly, Mr. F. W. Rudler, and Mr. G. W. Bloxam be a Committee for the purpose of investigating the Prehistoric Race in the Greek Islands; that Mr. Bloxam be the Secretary, and that the sum of 20*l.* be placed at their disposal for the purpose.

That Dr. E. B. Tylor, Dr. G. M. Dawson, General Sir J. H. Lefroy, Dr. Daniel Wilson, Mr. R. G. Haliburton, and Mr. George W. Bloxam be reappointed a Committee for the purpose of investigating and publishing reports on the physical characters, languages, and industrial and social condition of the North-Western Tribes of the Dominion of Canada; that Mr. Bloxam be the Secretary, and that the sum of 50*l.* be placed at their disposal for the purpose.

That Mr. Francis Galton, Dr. Beddoe, Mr. Brabrook, Professor Cunningham, Professor Flower, Mr. J. Park Harrison, Professor A. Macalister, Dr. Muirhead, Mr. F. W. Rudler, Professor Thane, and Dr. Garson be reappointed a Committee for the purpose of defining the Racial Characteristics of the Inhabitants of the British Isles; that Dr. Garson be the Secretary, and that the sum of 10*l.* be placed at their disposal for the purpose.

Not involving Grants of Money.

That Mr. James N. Shoolbred and Sir William Thomson be reappointed a Committee for the purpose of reducing and tabulating the Tidal Observations in the English Channel made with the Dover tide-gauge,

and of connecting them with observations made on the French coast; and that Mr. Shoolbred be the Secretary.

That Professor Barrett, Professor Fitzgerald, and Professor Balfour Stewart be a Committee for the purpose of reporting on the Molecular Phenomena attending the Magnetisation of Iron; and that Professor Barrett be the Secretary.

That Professor G. H. Darwin and Professor J. C. Adams be reappointed a Committee for the Harmonic Analysis of Tidal Observations; and that Professor Darwin be the Secretary.

That Mr. John Murray, Professor Schuster, Sir William Thomson, Professor Sir H. E. Roscoe, Professor A. S. Herschel, Captain W. de W. Abney, Professor Bonney, Mr. R. H. Scott, and Dr. J. H. Gladstone be reappointed a Committee for the purpose of investigating the practicability of collecting and identifying Meteoric Dust, and of considering the question of undertaking regular observations in various localities; and that Mr. Murray be the Secretary.

That Professors A. Johnson, Macgregor, J. B. Cherriman, and H. J. Bovey and Mr. C. Carpmael be reappointed a Committee for the purpose of promoting Tidal Observations in Canada; and that Professor Johnson be the Secretary.

That Professor Sylvester, Professor Cayley, and Professor Salmon be reappointed a Committee for the purpose of calculating Tables of the Fundamental Invariants of Algebraic Forms; and that Professor Cayley be the Secretary.

That Professors Everett and Sir William Thomson, Mr. G. J. Symons, Sir A. C. Ramsay, Dr. A. Geikie, Mr. J. Glaisher, Mr. Pengelly, Professor Edward Hull, Professor Prestwich, Dr. C. Le Neve Foster, Professor A. S. Herschel, Professor G. A. Lebour, Mr. A. B. Wynne, Mr. Galloway, Mr. Joseph Dickinson, Mr. G. F. Deacon, Mr. E. Wethered, and Mr. A. Strahan be reappointed a Committee for the purpose of investigating the Rate of Increase of Underground Temperature downwards in various Localities of Dry Land and under Water; and that Professor Everett be the Secretary.

That Professor Cayley, Sir William Thomson, Mr. James Glaisher, and Mr. J. W. L. Glaisher (Secretary) be reappointed a Committee for the purpose of calculating certain tables in the Theory of Numbers connected with the divisors of a number.

That Professors Tilden and Ramsay and Dr. W. W. J. Nicol be a Committee for the purpose of investigating the subject of Vapour Pressures and Refractive Indices of Salt Solutions; and that Dr. W. W. J. Nicol be the Secretary.

That Professors Ramsay, Tilden, Marshall, and W. L. Goodwin be a Committee for the purpose of investigating certain Physical Constants of Solution, especially the expansion of saline solutions; and that Professor W. L. Goodwin be the Secretary.

That Professors W. A. Tilden and H. E. Armstrong be a Committee for the purpose of investigating Isomeric Naphthalene Derivatives; and that Professor H. E. Armstrong be the Secretary.

That Professor Sir H. E. Roscoe, Mr. Lockyer, Professors Dewar, Liveing, Schuster, W. N. Hartley, and Wolcott Gibbs, Captain Abney, and Dr. Marshall Watts be a Committee for the purpose of preparing a new series of Wave-length Tables of the Spectra of the Elements; and that Dr. Marshall Watts be the Secretary.

That Professors Dewar and A. W. Williamson, Dr. Marshall Watts, Captain Abney, Dr. Johnstone Stoney, Professors W. N. Hartley, McLeod, Carey Foster, A. K. Huntington, Emerson Reynolds, Reinold, and Liveing, Lord Rayleigh, Professor Schuster, and Professor W. Chandler Roberts be a Committee for the purpose of reporting upon the present state of our knowledge of Spectrum Analysis; and that Professor W. Chandler Roberts be the Secretary.

That Professor E. Hull, Dr. H. W. Crosskey, Captain Douglas Galton, Professor J. Prestwich, and Messrs. James Glaisher, E. B. Marten, G. H. Morton, James Parker, W. Pengelly, James Plant, I. Roberts, Fox Strangways, T. S. Stooke, G. J. Symons, W. Topley, Tylden-Wright, E. Wethered, W. Whitaker, and C. E. De Rance be reappointed a Committee for the purpose of investigating the Circulation of the Underground Waters in the Permeable Formations of England, and the Quality and Quantity of the Waters supplied to various towns and districts from these formations; and that Mr. De Rance be the Secretary.

That Professors J. Prestwich, W. Boyd Dawkins, T. McK. Hughes, and T. G. Bonney, Dr. H. W. Crosskey, and Messrs. C. E. De Rance, H. G. Fordham, J. E. Lee, D. Mackintosh, W. Pengelly, J. Plant, and R. H. Tiddeman be reappointed a Committee for the purpose of recording the position, height above the sea, lithological characters, size, and origin of the Erratic Blocks of England, Wales, and Ireland, reporting other matters of interest connected with the same, and taking measures for their preservation; and that Dr. Crosskey be the Secretary.

That Sir A. Taylor, Professor Bayley Balfour, Dr. Crombie Brown, Dr. Cleghorn, and Sir John Lubbock be a Committee for the purpose of considering whether the condition of our Forests and Woodlands might not be improved by the establishment of a Forest School.

That Sir Joseph D. Hooker, Sir George Nares, Mr. John Murray, General J. T. Walker, Admiral Sir Leopold McClintock, Dr. W. B. Carpenter, Mr. Clements Markham, and Admiral Sir Erasmus Ommanney, be a Committee for the purpose of drawing attention to the desirability of further research in the Antarctic Regions, nearly half a century having elapsed since the last exploration; and that Admiral Sir Erasmus Ommanney be the Secretary.

That General J. T. Walker, Sir J. H. Lefroy, Sir William Thomson, Mr. Alexander Buchan, Mr. J. Y. Buchanan, Mr. John Murray, Mr. Francis Galton, Mr. H. W. Bates, and Mr. E. G. Ravenstein, with power to add to their number, be a Committee for the purpose of taking into consideration the combination of the Ordnance and Admiralty Surveys, and the production of a batho-hypsographical map of the British Islands; and that Mr. E. G. Ravenstein be the Secretary.

That General J. T. Walker, Sir William Thomson, Sir J. H. Lefroy, General R. Strachey, Professor A. S. Herschel, Professor G. Chrystal, Professor C. Niven, Professor J. H. Poynting, and Professor A. Schuster be a Committee for the purpose of inviting designs for a good Differential Gravity Meter in supersession of the pendulum, whereby satisfactory results may be obtained, at each station of observation, in a few hours, instead of the many days over which it is necessary to extend pendulum observations; and that Professor J. H. Poynting be the Secretary.

That Dr. J. H. Gladstone, Professor Armstrong, Mr. William Shaen, Mr. Stephen Bourne, Miss Lydia Becker, Sir John Lubbock, Dr. H. W. Crosskey, Sir Richard Temple, Sir Henry E. Roscoe, Mr. James

Heywood, and Professor N. Story Maskelyne be reappointed a Committee for the purpose of continuing the inquiries relating to the teaching of Science in Elementary Schools; and that Dr. J. H. Gladstone be the Secretary.

That the Corresponding Societies Committee, consisting of Mr. F. Galton, Professor Williamson, Captain Douglas Galton, Professor Boyd Dawkins, Sir Rawson Rawson, Dr. Garson, Mr. J. Evans, Mr. J. Hopkinson, Mr. Whitaker, Mr. Symons, Professor Meldola (Secretary), and General Pitt-Rivers, be reappointed.

That Mr. Mollison be requested to report on the present state of our knowledge of the Mathematical Theory of Thermal Conduction.

That Mr. P. T. Main be requested to draw up a Report on our experimental knowledge of the Properties of Matter with respect to volume, pressure, temperature, and specific heat.

That Mr. Glazebrook be requested to continue his Report on Optics.

That Professor J. J. Thomson be requested to continue his Report on Electrical Theories.

Communications ordered to be printed in extenso *in the Annual Report of the Association.*

Mr. Meldrum's paper, 'A Tabular Statement of the dates at which, and the localities where Pumice or Volcanic Dust was seen in the Indian Ocean' (with one plate).

Professor O. J. Lodge's paper 'On Electrolysis,' opening the discussion on Electrolysis.

Mr. Harker's paper 'On Slaty Cleavage.'

That Mr. Whitaker be requested to enlarge his List of Works on the Geology of Staffordshire by the addition of lists on Warwickshire and Worcestershire, and that the same be printed in full in the Report.

Mr. Stephen Bourne's paper 'On the use of Index Numbers in the Investigation of Trade Statistics.'

Mr. W. H. Preece's paper 'On the Strength of Telegraph Poles.'

Mr. A. S. Biggart's paper 'On the Forth Bridge Works,' with the necessary plates.

Mr. J. N. Shoolbred's paper 'On the Electric Lighting of the Forth Bridge.'

Mr. C. Barlow's paper 'On the Tay Bridge,' with the necessary plates.

Resolutions referred to the Council for Consideration, and Action if desirable.

That the Council be requested to reconsider the proposal of holding a General International Congress, and to report to the General Committee thereon at the next Meeting of the Association.

That the Council be requested to consider the desirability of admitting ladies as Officers of the Association, or as Members of the General or Sectional Committees.

That the Council be requested to consider the advisability of rendering the special Reports of the Association more accessible to the scientific public by placing them on sale in separate form.

That the printed Reports on Special Subjects be offered for sale to

the general public at the time of the Meeting, or as soon afterwards as possible.

That the Council be requested to so modify the Rules of the Association as to permit of a Sectional Meeting being held at an earlier hour than eleven, and the Sectional Committee previously, due notice being given to the Section on the previous day.

That a memorial be presented to H.M. Government requesting them to enlarge the existing Agricultural Department of the Privy Council, with the view of concentrating all administrative functions relating to Agriculture in one fully-equipped Board and Department of Agriculture.

That the Council be requested to consider and take steps, if they think it desirable, to memorialise the Government to undertake the more systematic collection and annual publication of Statistics of Wages, and a periodical industrial census.

That a memorial be presented to H.M. Government in favour of the establishment of a National School of Forestry.

Synopsis of Grants of Money appropriated to Scientific Purposes by the General Committee at the Aberdeen Meeting in September 1885. The Names of the Members entitled to call on the General Treasurer for the respective Grants are prefixed.

Mathematics and Physics.

The Annual Meeting in 1886.

The Meeting at Birmingham will commence on Wednesday, September 1.

Place of Meeting in 1887.

The Annual Meeting of the Association will be held at Manchester.

General Statement of Sums which have been paid on account of Grants for Scientific Purposes.

General Meetings.

On Wednesday, September 9, at 8 P.M., in the Music Hall, the Right Hon. Lord Rayleigh, M.A., D.C.L., LL.D., F.R.S., F.R.A.S., F.R.G.S., resigned the office of President to the Right Hon. Sir Lyon Playfair, K.C.B., M.P., Ph.D., LL.D., F.R.S. L. & E., F.C.S., who took the Chair, and delivered an Address, for which see page 1.

On Thursday, September 10, at 8 P.M., a Soirée took place in the Art Gallery.

On Friday, September 11, at 8 P.M., in the Music Hall, Professor W. G. Adams, M.A., F.R.S., F.G.S., delivered a Discourse on 'The Electric Light and Atmospheric Absorption.'

On Monday, September 14, at 8.30 P.M., in the Music Hall, Mr. John Murray, F.R.S.E., delivered a Discourse on 'The Great Ocean Basins.'

On Tuesday, September 15, at 8 P.M., a Soirée took place in the Art Gallery.

On Wednesday, September 16, at 2.30 P.M., the concluding General Meeting took place in St. Katherine's Hall, when the Proceedings of the General Committee and the Grants of Money for Scientific purposes were explained to the Members.

The Meeting was then adjourned to Birmingham. [The Meeting is appointed to commence on Wednesday, September 1, 1886.]

PRESIDENT'S ADDRESS.

ADDRESS

BY

THE RIGHT HON. SIR LYON PLAYFAIR,

K.C.B., M.P., F.R.S.

PRESIDENT.

I. *Visit to Canada.*

Our meeting at Montreal was a notable event in the life of the British Association, and even marked a distinct epoch in the history of civilisation. It was by no mere accident that the constitution of the Association enabled it to embrace all parts of the British Empire. Science is truly catholic, and is bounded only by the universe. In relation to our vast empire, science, as well as literature and art, is the common possession of all its varying people. The United Kingdom is limited to 120,800 square miles, inhabited by 35 millions of people; but the empire as a whole has $8\frac{1}{2}$ millions of square miles, with a population of 305 millions. To federate such vast possessions and so teeming a population into a political unit is a work only to be accomplished by the labours and persistent efforts of perhaps several generations of statesmen. The federation of its science is a subject of less dimensions well within the range of experiment. No part of the British Empire was more suited than Canada to try whether her science could be federated with our science. Canada has lately federated distinct provinces, with conflicting interests arising from difference of races, nationalities, and religions. Political federation is not new in the history of the world, though it generally arises as a consequence of war. It was war that taught the Netherlands to federate in 1619. It was war which united the States in America; federated Switzerland, Germany, and Austria, and unified Italy. But Canada formed a great national life out of petty provincial existences in a time of profound peace. This evolution gave an immense impulse to her national resources. The Dominion still requires consolidation in its vast extent, and applied science is rapidly effecting it. Canada, with its great expanse of territory, nearly as large as the United States, is being knit

together by the iron bands of railways from the Gulf of St. Lawrence to the Pacific Ocean, so that the fertile lands of Ontario, Manitoba, Columbia, and the North-Western Territories will soon be available to the world. Still practical science has much to accomplish. England and France, with only one-fifth the fertile area of Canada, support 80 millions of people, while Canada has a population not exceeding 5 millions.

A less far-seeing people than the Canadians might have invited the applied science which they so much require. But they knew that without science there are no applications. They no doubt felt with Emerson—

> And what if Trade sow cities
> Like shells along the shore,
> And thatch with towns the prairie broad
> With railways ironed o'er;
> They are but sailing foam-bells
> Along Thought's causing stream,
> And take their shape and sun-colour
> From him that sends the dream.

So it was with a far-reaching foresight that the Canadian Government invited the British Association for the Advancement of Science to meet in Montreal. The inhabitants of Canada received us with open arms, and the science of the Dominion and that of the United Kingdom were welded. We found in Canada, as we had every reason to expect, men of manly and self-reliant character who loved not less than we did the old home from which they had come. Among them is the same healthiness of political and moral life, with the same love of truth which distinguishes the English people. Our great men are their great men; our Shakspeare, Milton, and Burns belong to them as much as to ourselves; our Newton, Dalton, Faraday, and Darwin are their men of science as much as they are ours. Thus a common possession and mutual sympathy made the meeting in Canada a successful effort to stimulate the progress of science, while it established, at the same time, the principle that all people of British origin—and I would fain include our cousins in the United States—possess a common interest in the intellectual glories of their race, and ought, in science at least, to constitute part and parcel of a common empire, whose heart may beat in the small islands of the Northern seas, but whose blood circulates in all her limbs, carrying warmth to them and bringing back vigour to us. Nothing can be more cheering to our Association than to know that many of the young communities of English-speaking people all over the globe—in India, China, Japan, the Straits, Ceylon, Australia, New Zealand, the Cape—have founded scientific societies in order to promote the growth of scientific research. No doubt science, which is only a form of truth, is one in all lands, but still its unity of purpose and fulfilment received an important practical expression by our visit to Canada. This community of science will be continued by the fact that we have invited Sir William Dawson, of Montreal, to be our next President at Birmingham.

II. *Science and the State.*

I cannot address you in Aberdeen without recollecting that when we last met in this city our President was a great prince. The just verdict of time is that, high as was his royal rank, he has a far nobler claim to our regard as a lover of humanity in its widest sense, and especially as a lover of those arts and sciences which do so much to adorn it. On September 14, 1859, I sat on this platform and listened to the eloquent address and wise counsel of the Prince Consort. At one time a member of his household, it was my privilege to co-operate with this illustrious prince in many questions relating to the advancement of science. I naturally, therefore, turned to his presidential address to see whether I might not now continue those counsels which he then gave with all the breadth and comprehensiveness of his masterly speeches. I found, as I expected, a text for my own discourse in some pregnant remarks which he made upon the relation of Science to the State. They are as follows:—'We may be justified in hoping . . . that the Legislature and the State will more and more recognise the claims of science to their attention, so that it may no longer require the begging-box, but speak to the State like a favoured child to its parent, sure of his paternal solicitude for its welfare; that the State will recognise in science one of its elements of strength and prosperity, to foster which the clearest dictates of self-interest demand.'

This opinion, in its broadest sense, means that the relations of science to the State should be made more intimate because the advance of science is needful to the public weal.

The importance of promoting science as a duty of statecraft was well enough known to the ancients, especially to the Greeks and Arabs, but it ceased to be recognised in the dark ages, and was lost to sight during the revival of letters in the fifteenth and sixteenth centuries. Germany and France, which are now in such active competition in promoting science, have only publicly acknowledged its national importance in recent times. Even in the last century, though France had its Lavoisier and Germany its Leibnitz, their Governments did not know the value of science. When the former was condemned to death in the Reign of Terror, a petition was presented to the rulers that his life might be spared for a few weeks in order that he might complete some important experiments, but the reply was, 'The Republic has no need of savants.' Earlier in the century the much-praised Frederick William of Prussia shouted with a loud voice, during a graduation ceremony in the University of Frankfort, 'An ounce of mother-wit is worth a ton of university wisdom.' Both France and Germany are now ashamed of these utterances of their rulers, and make energetic efforts to advance science with the aid of their national resources. More remarkable is it to see a young nation like the United States reserving large tracts of its national lands for the promotion of scientific education. In some respects this young country is in advance of all

together by the iron bands of railways from the Gulf of St. Lawrence to the Pacific Ocean, so that the fertile lands of Ontario, Manitoba, Columbia, and the North-Western Territories will soon be available to the world. Still practical science has much to accomplish. England and France, with only one-fifth the fertile area of Canada, support 80 millions of people, while Canada has a population not exceeding 5 millions.

A less far-seeing people than the Canadians might have invited the applied science which they so much require. But they knew that without science there are no applications. They no doubt felt with Emerson—

> And what if Trade sow cities
> Like shells along the shore,
> And thatch with towns the prairie broad
> With railways ironed o'er;
> They are but sailing foam-bells
> Along Thought's causing stream,
> And take their shape and sun-colour
> From him that sends the dream.

So it was with a far-reaching foresight that the Canadian Government invited the British Association for the Advancement of Science to meet in Montreal. The inhabitants of Canada received us with open arms, and the science of the Dominion and that of the United Kingdom were welded. We found in Canada, as we had every reason to expect, men of manly and self-reliant character who loved not less than we did the old home from which they had come. Among them is the same healthiness of political and moral life, with the same love of truth which distinguishes the English people. Our great men are their great men; our Shakspeare, Milton, and Burns belong to them as much as to ourselves; our Newton, Dalton, Faraday, and Darwin are their men of science as much as they are ours. Thus a common possession and mutual sympathy made the meeting in Canada a successful effort to stimulate the progress of science, while it established, at the same time, the principle that all people of British origin—and I would fain include our cousins in the United States—possess a common interest in the intellectual glories of their race, and ought, in science at least, to constitute part and parcel of a common empire, whose heart may beat in the small islands of the Northern seas, but whose blood circulates in all her limbs, carrying warmth to them and bringing back vigour to us. Nothing can be more cheering to our Association than to know that many of the young communities of English-speaking people all over the globe—in India, China, Japan, the Straits, Ceylon, Australia, New Zealand, the Cape—have founded scientific societies in order to promote the growth of scientific research. No doubt science, which is only a form of truth, is one in all lands, but still its unity of purpose and fulfilment received an important practical expression by our visit to Canada. This community of science will be continued by the fact that we have invited Sir William Dawson, of Montreal, to be our next President at Birmingham.

II. *Science and the State.*

I cannot address you in Aberdeen without recollecting that when we last met in this city our President was a great prince. The just verdict of time is that, high as was his royal rank, he has a far nobler claim to our regard as a lover of humanity in its widest sense, and especially as a lover of those arts and sciences which do so much to adorn it. On September 14, 1859, I sat on this platform and listened to the eloquent address and wise counsel of the Prince Consort. At one time a member of his household, it was my privilege to co-operate with this illustrious prince in many questions relating to the advancement of science. I naturally, therefore, turned to his presidential address to see whether I might not now continue those counsels which he then gave with all the breadth and comprehensiveness of his masterly speeches. I found, as I expected, a text for my own discourse in some pregnant remarks which he made upon the relation of Science to the State. They are as follows:—'We may be justified in hoping . . . that the Legislature and the State will more and more recognise the claims of science to their attention, so that it may no longer require the begging-box, but speak to the State like a favoured child to its parent, sure of his paternal solicitude for its welfare; that the State will recognise in science one of its elements of strength and prosperity, to foster which the clearest dictates of self-interest demand.'

This opinion, in its broadest sense, means that the relations of science to the State should be made more intimate because the advance of science is needful to the public weal.

The importance of promoting science as a duty of statecraft was well enough known to the ancients, especially to the Greeks and Arabs, but it ceased to be recognised in the dark ages, and was lost to sight during the revival of letters in the fifteenth and sixteenth centuries. Germany and France, which are now in such active competition in promoting science, have only publicly acknowledged its national importance in recent times. Even in the last century, though France had its Lavoisier and Germany its Leibnitz, their Governments did not know the value of science. When the former was condemned to death in the Reign of Terror, a petition was presented to the rulers that his life might be spared for a few weeks in order that he might complete some important experiments, but the reply was, 'The Republic has no need of savants.' Earlier in the century the much-praised Frederick William of Prussia shouted with a loud voice, during a graduation ceremony in the University of Frankfort, 'An ounce of mother-wit is worth a ton of university wisdom.' Both France and Germany are now ashamed of these utterances of their rulers, and make energetic efforts to advance science with the aid of their national resources. More remarkable is it to see a young nation like the United States reserving large tracts of its national lands for the promotion of scientific education. In some respects this young country is in advance of all

European nations in joining science to its administrative offices. Its scientific publications, like the great palæontological work embodying the researches of Professor Marsh and his associates in the Geological Survey, are an example to other Governments. The Minister of Agriculture is surrounded with a staff of botanists and chemists. The Home Secretary is aided by a special Scientific Commission to investigate the habits, migrations, and food of fishes, and the latter has at its disposal two specially-constructed steamers of large tonnage. The United States and Great Britain promote fisheries on distinct systems. In this country we are perpetually issuing expensive Commissions to visit the coasts in order to ascertain the experiences of fishermen. I have acted as Chairman of one of these Royal Commissions, and found that the fishermen, having only a knowledge of a small area, gave the most contradictory and unsatisfactory evidence. In America the questions are put to Nature, and not to fishermen. Exact and searching investigations are made into the life-history of the fishes, into the temperature of the sea in which they live and spawn, into the nature of their food, and into the habits of their natural enemies. For this purpose the Government give the co-operation of the navy, and provide the Commission with a special corps of skilled naturalists, some of whom go out with the steamships and others work in the biological laboratories at Wood's Holl, Massachusetts, or at Washington. The different universities send their best naturalists to aid in these investigations, which are under the direction of Mr. Baird, of the Smithsonian Institution. The annual cost of the Federal Commission is about 40,000*l.*, while the separate States spend about 20,000*l.* in local efforts. The practical results flowing from these scientific investigations have been important. The inland waters and rivers have been stocked with fish of the best and most suitable kinds. Even the great ocean which washes the coasts of the United States is beginning to be affected by the knowledge thus acquired, and a sensible result is already produced upon the most important of its fisheries. The United Kingdom largely depends upon its fisheries, but as yet our Government have scarcely realised the value of such scientific investigations as those pursued with success by the United States. Less systematically, but with great benefit to science, our own Government has used the surveying expeditions, and sometimes has equipped special expeditions to promote natural history and solar physics. Some of the latter, like the voyage of the 'Challenger,' have added largely to the store of knowledge; while the former, though not primarily intended for scientific research, have had an indirect result of infinite value by becoming training-schools for such investigators as Edward Forbes, Darwin, Hooker, Huxley, Wyville Thomson, and others.

In the United Kingdom we are just beginning to understand the wisdom of Washington's farewell address to his countrymen, when he said: 'Promote as an object of primary importance institutions for the general diffusion of knowledge. In proportion as the structure of a government

gives force to public opinion, it is essential that public opinion should be enlightened.' It was only in 1870 that our Parliament established a system of national primary education. Secondary education is chaotic, and remains unconnected with the State, while the higher education of the universities is only brought at distant intervals under the view of the State. All great countries except England have Ministers of Education, but this country has only Ministers who are the managers of primary schools. We are inferior even to smaller countries in the absence of organised State supervision of education. Greece, Portugal, Egypt, and Japan have distinct Ministers of Education, and so also among our Colonies have Victoria and New Zealand. Gradually England is gathering materials for the establishment of an efficient Education Minister. The Department of Science and Art is doing excellent work in diffusing a taste for elementary science among the working classes. There are now about 78,000 persons who annually come under the influence of its science classes, while a small number of about two hundred, many of them teachers, receive thorough instruction in science at the excellent school in South Kensington of which Professor Huxley is the Dean. I do not dwell on the work of this Government department, because my object is chiefly to point out how it is that science lags in its progress in the United Kingdom owing to the deficient interest taken in it by the middle and upper classes. The working classes are being roused from their indifference. They show this by their selection of scientific men as candidates at the next election. Among these are Professors Stuart, Roscoe, Maskelyne, and Rücker. It has its significance that such a humble representative of science as myself received invitations from working-class constituencies in more than a dozen of the leading manufacturing towns. In the next Parliament I do not doubt that a Minister of Education will be created as a nucleus round which the various educational materials may crystallise in a definite form.

III. *Science and Secondary Education.*

Various Royal Commissions have made inquiries and issued recommendations in regard to our public and endowed schools. The Commissions of 1861, 1864, 1868, and 1873 have expressed the strongest disapproval of the condition of our schools, and, so far as science is concerned, their state is much the same as when the Duke of Devonshire's Commission in 1873 reported in the following words:—'Considering the increasing importance of science to the material interests of the country, we cannot but regard its almost total exclusion from the training of the upper and middle classes as little less than a national misfortune.' No doubt there are exceptional cases and some brilliant examples of improvement since these words were written, but generally throughout the country teaching in science is a name rather than a reality. The Technical Commission which reported last year can only point to three schools in Great Britain in which science is fully and adequately taught.

While the Commission gives us the consolation that England is still in advance as an industrial nation, it warns us that foreign nations, which were not long ago far behind, are now making more rapid progress than this country, and will soon pass it in the race of competition unless we give increased attention to science in public education. A few of the large towns, notably Manchester, Bradford, Huddersfield, and Birmingham, are doing so. The working classes are now receiving better instruction in science than the middle classes. The competition of actual life asserts its own conditions, for the children of the latter find increasing difficulty in obtaining employment. The cause of this lies in the fact that the schools for the middle classes have not yet adapted themselves to the needs of modern life. It is true that many of the endowed schools have been put under new schemes, but as there is no public supervision or inspection of them, we have no knowledge as to whether they have prospered or slipped back. Many corporate schools have arisen, some of them, like Clifton, Cheltenham, and Marlborough Colleges, doing excellent educational work, though as regards all of them the public have no rights and cannot enforce guarantees for efficiency. A Return just issued, on the motion of Sir John Lubbock, shows a lamentable deficiency in science teaching in a great proportion of the endowed schools. While twelve to sixteen hours per week are devoted to classics, two to three hours are considered ample for science in a large proportion of the schools. In Scotland there are only six schools in the Return which give more than two hours to science weekly, while in many schools its teaching is wholly omitted. Every other part of the kingdom stands in a better position than Scotland in relation to the science of its endowed schools. The old traditions of education stick as firmly to schools as a limpet does to a rock; though I do the limpet injustice, for it does make excursions to seek pastures new. Are we to give up in despair because an exclusive system of classical education has resisted the assaults of such cultivated authors as Milton, Montaigne, Cowley, and Locke? There was once an enlightened Emperor of China, Chi Hwangti, who knew that his country was kept back by its exclusive devotion to the classics of Confucius and Mencius. He invited 500 of the teachers to bring their copies of these authors to Pekin, and after giving a great banquet in their honour, he buried alive the professors along with their manuscripts in a deep pit. But Confucius and Mencius still reign supreme. I advocate milder measures, and depend for their adoption on the force of public opinion. The needs of modern life will force schools to adapt themselves to a scientific age. Grammar-schools believe themselves to be immortal. Those curious immortals—the Struldbrugs—described by Swift, ultimately regretted their immortality, because they found themselves out of touch, sympathy, and fitness with the centuries in which they lived.

As there is no use clamouring for an instrument of more compass and power until we have made up our mind as to the tune, Professor Huxley, in

his evidence before a Parliamentary Committee in 1884, has given a time-table for grammar-schools. He demands that out of their forty hours for public and private study, ten should be given to modern languages and history, eight to arithmetic and mathematics, six to science, and two to geography, thus leaving fourteen hours to the dead languages. No time-table would, however, be suitable to all schools. The great public schools of England will continue to be the gymnasia for the upper classes, and should devote much of their time to classical and literary culture. Even now they introduce into their curriculum subjects unknown to them when the Royal Commission of 1868 reported, though they still accept science with timidity. Unfortunately, the other grammar-schools which educate the middle classes look to the higher public schools as a type to which they should conform, although their functions are so different. It is in the interest of the higher public schools that this difference should be recognised, so that, while they give an all-round education and expand their curriculum by a freer recognition of the value of science as an educational power in developing the faculties of the upper classes, the schools for the middle classes should adapt themselves to the needs of their existence, and not keep up a slavish imitation of schools with a different function.

The stock argument against the introduction of modern subjects into grammar-schools is that it is better to teach Latin and Greek thoroughly rather than various subjects less completely. But is it true that thoroughness in teaching dead languages is the result of an exclusive system? In 1868 the Royal Commission stated that even in the few great public schools thoroughness was only given to thirty per cent. of the scholars, at the sacrifice of seventy per cent. who got little benefit from the system. Since then the curriculum has been widened and the teaching has improved. I question the soundness of the principle that it is better to limit the attention of the pupils mainly to Latin and Greek, highly as I value their educational power to a certain order of minds. As in biology the bodily development of animals is from the general to the special, so is it in the mental development of man. In the school a boy should be aided to discover the class of knowledge that is best suited for his mental capacities, so that, in the upper forms of the school and in the university, knowledge may be specialised in order to cultivate the powers of the man to their fullest extent. Shakspeare's educational formula may not be altogether true, but it contains a broad basis of truth—

> No profit grows, where is no pleasure ta'en;—
> In brief, sir, study what you most affect.

The comparative failure of the modern side of school education arises from constituting it out of the boys who are looked upon as classical asses. Milton pointed out that in all schools there are boys to whom the dead languages are 'like thorns and thistles,' which form a poor nourishment even for asses. If teachers looked upon these classical asses as beings who might receive mental nurture according to their nature,

much higher results would follow the bifurcation of our schools. Saul went out to look for asses and he found a kingdom. Surely this fact is more encouraging than the example of Gideon, who 'took thorns of the wilderness and briars, and with these he *taught* the men of Succoth.'[1] The adaptation of public schools to a scientific age does not involve a contest as to whether science or classics shall prevail, for both are indispensable to true education. The real question is whether schools will undertake the duty of moulding the minds of boys according to their mental varieties. Classics, from their structural perfection and power of awakening dormant faculties, have claims to precedence in education, but they have none to a practical monopoly. It is by claiming the latter that teachers sacrifice mental receptivity to a Procrustean uniformity.

The universities are changing their traditions more rapidly than the schools. The *via antiqua* which leads to them is still broad, though a *via moderna*, with branching avenues, is also open to their honours and emoluments. Physical science, which was once neglected, is now encouraged at the universities. As to the seventy per cent. of boys who leave schools for life-work without going through the universities, are there no growing signs of discontent which must force a change? The Civil Service, the learned professions, as well as the army and navy, are now barred by examinations. Do the boys of our public schools easily leap over the bars, although some of them have lately been lowered so as to suit the schools? So difficult are these bars to scholars that crammers take them in hand before they attempt the leap; and this occurs in spite of the large value attached to the dead languages and the small value placed on modern subjects. Thus, in the Indian Civil Service examinations, 800 marks as a maximum are assigned to Latin, 600 to Greek, 500 to chemistry, and 300 to each of the other physical sciences. But if we take the average working of the system for the last four years, we find that while sixty-eight per cent. of the maximum were given to candidates in Greek and Latin, only forty-five per cent. were accorded to candidates in chemistry, and but thirty per cent. to the other physical sciences. Schools sending up boys for competition naturally shun subjects which are dealt with so hardly and so heavily handicapped by the State.

Passing from learned or public professions to commerce, how is it that in our great commercial centres, foreigners—German, Swiss, Dutch, and even Greeks—push aside our English youth and take the places of profit which belong to them by national inheritance? How is it that in our Colonies, like those in South Africa, German enterprise is pushing aside English incapacity? How is it that we find whole branches of manufactures, when they depend on scientific knowledge, passing away from this country, in which they originated, in order to engraft themselves abroad, although their decaying roots remain at home?[2] The answer to

[1] Judges viii. 16.

[2] See Dr. Perkins' address to the Soc. Chem. Industry. 'Nature,' Aug. 6, 1885, p. 333.

these questions is that our systems of education are still too narrow for the increasing struggle of life.

Faraday, who had no narrow views in regard to education, deplored the future of our youth in the competition of the world, because, as he said with sadness, 'our schoolboys, when they come out of school, are ignorant of their ignorance at the end of all that education.'

The opponents of science education allege that it is not adapted for mental development, because scientific facts are often disjointed and exercise only the memory. Those who argue thus do not know what science is. No doubt an ignorant or half-informed teacher may present science as an accumulation of unconnected facts. At all times and in all subjects there are teachers without æsthetical or philosophical capacity—men who can only see carbonate of lime in a statue by Phidias or Praxiteles; who cannot survey zoology on account of its millions of species, or botany because of its 130,000 distinct plants; men who can look at trees without getting a conception of a forest, and cannot distinguish a stately edifice from its bricks. To teach in that fashion is like going to the tree of science with its glorious fruit in order to pick up a handful of the dry fallen leaves from the ground. It is, however, true that as science teaching has had less lengthened experience than that of literature, its methods of instruction are not so matured. Scientific and literary teaching have different methods; for while the teacher of literature rests on authority and on books for his guidance, the teacher of science discards authority and depends on facts at first hand, and on the book of Nature for their interpretation. Natural science more and more resolves itself into the teaching of the laboratory. In this way it can be used as a powerful means of quickening observation, and of creating a faculty of induction after the manner of Zadig, the Babylonian described by Voltaire. Thus facts become surrounded by scientific conceptions, and are subordinated to order and law.

It is not those who desire to unite literature with science who degrade education; the degradation is the consequence of the refusal. A violent reaction—too violent to be wise—has lately taken place against classical education in France, where their own vernacular occupies the position of dead languages, while Latin and science are given the same time in the curriculum. In England manufacturers cry out for technical education, in which classical culture shall be excluded. In the schools of the middle classes science rather than technics is needed, because, when the seeds of science are sown, technics as its fruit will appear at the appointed time. Epictetus was wise when he told us to observe that, though sheep eat grass, it is not grass but wool that grows on their backs. Should, however, our grammar-schools persist in their refusal to adapt themselves to the needs of a scientific age, England must follow the example of other European nations and found new modern schools in competition with them. For, as Huxley has put it, we cannot continue in this age 'of full modern artillery to turn out our boys to do battle in it, equipped only

with the sword and shield of an ancient gladiator.' In a scientific and keenly competitive age an exclusive education in the dead languages is a perplexing anomaly. The flowers of literature should be cultivated and gathered, though it is not wise to send men into our fields of industry to gather the harvest when they have been taught only to cull the poppies and to push aside the wheat.

IV. *Science and the Universities.*

The State has always felt bound to alter and improve universities, even when their endowments are so large as to render it unnecessary to support them by public funds. When universities are poor, Parliament gives aid to them from imperial taxation. In this country that aid has been given with a very sparing hand. Thus the universities and colleges of Ireland have received about thirty thousand pounds annually, and the same sum has been granted to the four universities of Scotland. Compared with imperial aid to foreign universities such sums are small. A single German university like Strasburg or Leipsic receives above 40,000*l.* annually, or 10,000*l.* more than the whole colleges of Ireland or of Scotland. Strasburg, for instance, has had her university and its library rebuilt at a cost of 711,000*l.*, and receives an annual subscription of 43,000*l.* In rebuilding the university of Strasburg eight laboratories have been provided, so as to equip it fully with the modern requirements for teaching and research.[1] Prussia, the most economical nation in the world, spends 391,000*l.* yearly out of taxation on her universities.

The recent action of France is still more remarkable. After the Franco-German War the Institute of France discussed the important question:—'Pourquoi la France n'a pas trouvé d'hommes supérieurs au moment du péril?' The general answer was because France had allowed university education to sink to a low ebb. Before the great Revolution France had twenty-three autonomous universities in the provinces. Napoleon desired to found one great university at Paris, and he crushed out the others with the hand of a despot, and remodelled the last with the instincts of a drill-sergeant. The central university sank so low that in 1868 it is said that only 8,000*l.* were spent for true academic purposes. Startled by the intellectual sterility shown in the war, France has made gigantic efforts to retrieve her position, and has rebuilt the provincial colleges at a cost of 3,280,000*l.*, while her annual budget for their support now reaches half a million of pounds. In order to open these provincial colleges to the best talent of France, more than five hundred scholarships have been founded at an annual cost of 30,000*l.* France now recognises that it is not by the number of men under arms that she can compete with her great neighbour Germany, so she has determined to equal her in intellect.

[1] The cost of these laboratories has been as follows:—Chemical Institute, 35,000*l.*; Physical Institute, 28,000*l.*; Botanical Institute, 26,000*l.*; Observatory, 25,000*l.*; Anatomy, 42,000*l.*; Clinical Surgery, 26,000*l.*; Physiological Chemistry, 16,000*l.*; Physiological Institute, 13,900*l.*

You will understand why it is that Germany was obliged, even if she had not been willing, to spend such large sums in order to equip the university of her conquered province, Alsace-Lorraine. France and Germany are fully aware that science is the source of wealth and power, and that the only way of advancing it is to encourage universities to make researches and to spread existing knowledge through the community. Other European nations are advancing on the same lines. Switzerland is a remarkable illustration of how a country can compensate itself for its natural disadvantages by a scientific education of its people. Switzerland contains neither coal nor the ordinary raw materials of industry, and is separated from other countries which might supply them by mountain barriers. Yet, by a singularly good system of graded schools, and by the great technical college of Zürich, she has become a prosperous manufacturing country. In Great Britain we have nothing comparable to this technical college, either in magnitude or efficiency. Belgium is reorganising its universities, and the State has freed the localities from the charge of buildings, and will in future equip the universities with efficient teaching resources out of public taxation. Holland, with a population of 4,000,000 and a small revenue of 9,000,000*l.*, spends 136,000*l.* on her four universities. Contrast this liberality of foreign countries in the promotion of higher instruction with the action of our own country. Scotland, like Holland, has four universities, and is not very different from it in population, but it only receives 30,000*l.* from the State. By a special clause in the Scotch Universities Bill the Government asked Parliament to declare that under no circumstances should the Parliamentary grant be ever increased above 40,000*l.* According to the views of the British Treasury there is a finality in science and in expanding knowledge.

The wealthy universities of Oxford and Cambridge are gradually constructing laboratories for science. The merchant princes of Manchester have equipped their new Victoria University with similar laboratories. Edinburgh and Glasgow Universities have also done so, partly at the cost of Government and largely by private subscriptions. The poorer universities of Aberdeen and St. Andrews are still inefficiently provided with the modern appliances for teaching science.

London has one small Government college and two chartered colleges, but is wholly destitute of a teaching university. It would excite great astonishment at the Treasury if we were to make the modest request that the great metropolis, with a population of four millions, should be put into as efficient academical position as the town of Strasburg, with 104,000 inhabitants, by receiving, as that town does, 43,000*l.* annually for academic instruction, and 700,000*l.* for university buildings. Still, the amazing anomaly that London has no teaching university must ere long cease.

It is a comforting fact that, in spite of the indifference of Parliament, the large towns of the kingdom are showing their sense of the need of

higher education. Manchester has already its university. Nottingham, Birmingham, Leeds, and Bristol have colleges more or less complete. Liverpool converts a disused lunatic asylum into a college for sane people. Cardiff rents an infirmary for a collegiate building. Dundee, by private benefaction, rears a Baxter College with larger ambitions. All these are healthy signs that the public are determined to have advanced science teaching; but the resources of the institutions are altogether inadequate to the end in view. Even in the few cases where the laboratories are efficient for teaching purposes, they are inefficient as laboratories for research. Under these circumstances the Royal Commission on Science advocates special Government laboratories for research. Such laboratories, supported by public money, are as legitimate subjects for expenditure as galleries for pictures or sculpture; but I think that they would not be successful, and would injure science if they failed. It would be safer in the meantime if the State assisted universities or well-established colleges to found laboratories of research under their own care. Even such a proposal shocks our Chancellor of the Exchequer, who tells us that this country is burdened with public debt, and has ironclads to build and arsenals to provide. Nevertheless our wealth is proportionally much greater than that of foreign States which are competing with so much vigour in the promotion of higher education. They deem such expenditure to be true economy, and do not allow their huge standing armies to be an apology for keeping their people backwards in the march of knowledge. France, which in the last ten years has been spending a million annually on university education, had a war indemnity to pay, and competes successfully with this country in ironclads. Either all foreign States are strangely deceived in their belief that the competition of the world has become a competition of intellect, or we are marvellously unobservant of the change which is passing over Europe in the higher education of the people. Preparations for war will not ensure to us the blessings and security of an enlightened peace. Protective expenditure may be wise, though productive expenditure is wiser.

> Were half the powers which fill the world with terror,
> Were half the wealth bestowed on camps and courts,
> Given to redeem the human mind from error—
> There were no need of arsenals and forts.

Universities are not mere storehouses of knowledge; they are also conservatories for its cultivation. In Mexico there is a species of ant which sets apart some of its individuals to act as honey-jars by monstrously extending their abdomens to store the precious fluid till it is wanted by the community. Professors in a university have a higher function, because they ought to make new honey as well as to store it. The widening of the bounds of knowledge, literary or scientific, is the crowning glory of university life. Germany unites the functions of teaching and research in the universities, while France keeps them in separate institutions. The former system is best adapted to our habits, but its

condition for success is that our science chairs should be greatly increased, so that teachers should not be wholly absorbed in the duties of instruction. Germany subdivides the sciences into various chairs, and gives to the professors special laboratories. It also makes it a condition for the higher honours of a university that the candidates shall give proofs of their ability to make original researches. Under such a system, teaching and investigation are not incompatible. In the evidence before the Science Commission many opinions were given that scientific men engaged in research should not be burdened with the duties of education, and there is much to be said in support of this view when a single professor for the whole range of a physical science is its only representative in a university. But I hope that such a system will not long continue, for if it do we must occupy a very inferior position as a nation in the intellectual competition of Europe. Research and education in limited branches of higher knowledge are not incompatible. It is true that Galileo complained of the burden imposed upon him by his numerous astronomical pupils, though few other philosophers have echoed this complaint. Newton, who produced order in worlds, and Dalton, who brought atoms under the reign of order and number, rejoiced in their pupils. Lalande spread astronomers as Liebig spread chemists, and Johannes Müller biologists, all over the world. Laplace, La Grange, Dulong, Gay Lussac, Berthollet, and Dumas were professors as well as discoverers in France. In England our discoverers have generally been teachers. In fact I recollect only three notable examples of men who were not—Boyle, Cavendish, and Joule. It was so in ancient as well as in modern times, for Plato and Aristotle taught and philosophised. If you do not make the investigator a schoolmaster, as Dalton was, and as practically our professors are at the present time, with the duty of teaching all branches of their sciences, the mere elementary truths as well as the highest generalisations being compressed into a course, it is well that they should be brought into contact with the world in which they live, so as to know its wants and aspirations. They could then quicken the pregnant minds around them, and extend to others their own power and love of research. Goethe had a fine perception of this when he wrote—

> Wer in der Weltgeschichte lebt,
> Wer in die Zeiten schaut, und strebt,
> Nur der ist werth, zu sprechen und zu dichten.

Our universities are still far from the attainment of a proper combination of their resources between teaching and research. Even Oxford and Cambridge, which have done so much in recent years in the equipment of laboratories and in adding to their scientific staff, are still far behind a second-class German university. The professional faculties of the English universities are growing, and will diffuse a greater taste for science among their students, though they may absorb the time of the limited professoriate so as to prevent it advancing the boundaries of

knowledge. Professional faculties are absolutely essential to the existence of universities in poor countries like Scotland and Ireland. This has been the case from the early days of the Bologna University up to the present time. Originally universities arose not by mere bulls of popes, but as a response to the strong desire of the professional classes to dignify their crafts by real knowledge. If their education had been limited to mere technical schools like the Medical School of Salerno which flourished in the eleventh century, length but not breadth would have been given to education. So the universities wisely joined culture to the professional sciences. Poor countries like Scotland and Ireland must have their academic systems based on the professional faculties, although wealthy universities like Oxford and Cambridge may continue to have them as mere supplements to a more general education. A greater liberality of support on the part of the State in the establishment of chairs of science, for the sake of science and not merely for the teaching of the professions, would enable the poorer universities to take their part in the advancement of knowledge.

I have already alluded to the foundation of new colleges in different parts of the kingdom. Owens College has worthily developed into the Victoria University. Formerly she depended for degrees on the University of London. No longer will she be like a moon reflecting cold and sickly rays from a distant luminary, for in future she will be a sun, a centre of intelligence, warming and illuminating the regions around her. The other colleges which have formed themselves in large manufacturing districts are remarkable expressions from them that science must be promoted. Including the colleges of a high class, such as University College and King's College in London, and the three Queen's Colleges in Ireland, the aggregate attendance of students in colleges without university rank is between nine and ten thousand, while that of the universities is fifteen thousand. No doubt some of the provincial colleges require considerable improvement in their teaching methods; sometimes they unwisely aim at a full university curriculum when it would be better for them to act as faculties. Still they are all growing in the spirit of self-help, and some of them are destined, like Owens College, to develop into universities. This is not a subject of alarm to lovers of education, while it is one of hope and encouragement to the great centres of industry. There are too few autonomous universities in England in proportion to its population. While Scotland, with a population of $3\frac{3}{4}$ millions, has four universities with 6,500 students, England, with 26 millions of people, has only the same number of teaching universities with 6,000 students. Unless English colleges have such ambition, they may be turned into mere mills to grind out material for examinations and competitions. Higher colleges should always hold before their students that knowledge, for its own sake, is the only object worthy of reverence. Beyond college life there is a land of research flowing with milk and honey for those who know how to cultivate it.

Colleges should at least show a Pisgah view of this Land of Promise, which stretches far beyond the Jordan of examinations and competitions.

V. *Science and Industry.*

In the popular mind the value of science is measured by its applications to the useful purposes of life. It is no doubt true that science wears a beautiful aspect when she confers practical benefits upon man. But truer relations of science to industry are implied in Greek mythology. Vulcan, the god of industry, wooed science, in the form of Minerva, with a passionate love, but the chaste goddess never married, although she conferred upon mankind nearly as many arts as Prometheus, who, like other inventors, saw civilisation progressing by their use while he lay groaning in want on Mount Caucasus. The rapid development of industry in modern days depends on the applications of scientific knowledge, while its slower growth in former times was due to experiments being made by trial and error in order to gratify the needs of man. Then an experiment was less a questioning of Nature than an exercise on the mind of the experimentalist. For a true questioning of Nature only arises when intellectual conceptions of the causes of phenomena attach themselves to ascertained facts as well as to their natural environments. Much real science had at one time accumulated in Egypt, Greece, Rome, and Arabia, though it became obscured by the intellectual darkness which spread over Europe like a pall for many centuries. The mental results of Greek science, filtered through the Romans and Arabians, gradually fertilised the soil of Europe. Even in ages which are deemed to be dark and unprolific, substantial though slow progress was made. By the end of the fifteenth century the mathematics of the Alexandrian school had become the possession of Western Europe; Arabic numerals, algebra, trigonometry, decimal reckoning, and an improved calendar having been added to its stock of knowledge. The old discoveries of Democritus and Archimedes in physics, and of Hipparchus and Ptolemy in astronomy, were producing their natural developments, though with great slowness. Many manufactures, growing chiefly by experience, and occasionally lightened up by glimmerings of science throughout the prevailing darkness, had arisen before the sixteenth century. A knowledge of the properties of bodies, though scarcely of their relations to each other, came through the labours of the alchemists, who had a mighty impulse to work, for by the philosopher's stone, often not larger than half a rapeseed, they hoped to attain the three sensuous conditions of human enjoyment, gold, health, and immortality. By the end of the fifteenth century many important manufactures were founded by empirical experiment, with only the uncertain guidance of science. Among these were the compass, printing, paper, gunpowder, guns, watches, forks, knitting-needles, horseshoes, bells, wood cutting and copper engraving, wire-drawing, steel, table glass, spectacles, microscopes, glass mirrors backed by amalgams of tin and lead, windmills, crushing and saw mills. These

important manufactures arose from an increased knowledge of facts, around which scientific conceptions were slowly concreting. Aristotle defines this as science when he says, 'Art begins when, from a great number of experiences, one general conception is formed which will embrace all similar cases.' Such conceptions are formed only when culture develops the human mind and compels it to give a rational account of the world in which man lives, and of the objects in and around it, as well as of the phenomena which govern their action and evolution. Though the accumulation of facts is indispensable to the growth of science, a thousand facts are of less value to human progress than is a single one when it is scientifically comprehended, for it then becomes generalised in all similar cases. Isolated facts may be viewed as the dust of science. The dust which floats in the atmosphere is to the common observer mere incoherent matter in a wrong place, while to the man of science it is all-important when the rays of heat and light act upon its floating particles. It is by them that clouds and rains are influenced; it is by their selective influence on the solar waves that the blue of the heavens and the beauteous colours of the sky glorify all Nature. So, also, ascertained though isolated facts, forming the dust of science, become the reflecting media of the light of knowledge, and cause all Nature to assume a new aspect. It is with the light of knowledge that we are enabled to question Nature through direct experiment. The hypothesis or theory which induces us to put the experimental question may be right or wrong; still, *prudens questio dimidium scientiæ est*—it is half way to knowledge when you know what you have to inquire. Davy described hypothesis as the mere scaffolding of science, useful to build up true knowledge, but capable of being put up or taken down at pleasure. Undoubtedly a theory is only temporary, and the reason is, as Bacon has said, that the man of science 'loveth truth more than his theory.' The changing theories which the world despises are the leaves of the tree of science drawing nutriment to the parent stems, and enabling it to put forth new branches and to produce fruit; and though the leaves fall and decay, the very products of decay nourish the roots of the tree and reappear in the new leaves or theories which succeed.

When the questioning of Nature by intelligent experiment has raised a system of science, then those men who desire to apply it to industrial inventions proceed by the same methods to make rapid progress in the arts. They also must have means to compel Nature to reveal her secrets. Æneas succeeded in his great enterprise by plucking a golden branch from the tree of science. Armed with this even dread Charon dared not refuse a passage across the Styx; and the gate of the Elysian fields was unbarred when he hung the branch on its portal. Then new aspects of Nature were revealed—

> Another sun and stars they know
> That shine like ours, but shine below.

It is by carrying such a golden branch from the tree of science that in-

ventors are able to advance the arts. In illustration of how slowly at first and how rapidly afterwards science and its applications arise, I will take only two out of thousands of examples which lie ready to my hand. One of the most familiar instances is air, for that surely should have been soon understood if man's unaided senses are sufficient for knowledge. Air has been under the notice of mankind ever since the first man drew his first breath. It meets him at every turn; it fans him with gentle breezes, and it buffets him with storms. And yet it is certain that this familiar object—air—is very imperfectly understood up to the present time. We now know by recent researches that air can be liquefied by pressure and cold; but as a child still looks upon air as nothing, so did man in his early state. A vessel filled with air was deemed to be empty. But man, as soon as he began to speculate, felt the importance of air, and deemed it to be a soul of the world upon which the respiration of man and the god-like quality of fire depended. Yet a really intelligent conception of these two essential conditions to man's existence—respiration and combustion—was not formed till about a century ago (1775). No doubt long before that time there had been abundant speculations regarding air. Anaximenes, 548 years before Christ, and Diogenes of Apollonia, a century later, studied the properties of air so far as their senses would allow them; so, in fact, did Aristotle. Actual scientific experiments were made on air about the year 1100 by a remarkable Saracen, Alhazen, who ascertained important truths which enabled Galileo, Torricelli, Otto de Guericke, and others at a later period to discover laws leading to important practical applications. Still there was no intelligent conception as to the composition of air until Priestley in 1774 repeated, with the light of science, an empirical observation which Eck de Sulbach had made three hundred years before upon the union of mercury with an ingredient of air and the decomposition of this compound by heat. This experiment now proved that the active element in air is oxygen. From that date our knowledge, derived from an intelligent questioning of air by direct experiments, has gone on by leaps and bounds. The air, which mainly consists of nitrogen and oxygen, is now known to contain carbonic acid, ammonia, nitric acid, ozone, besides hosts of living organisms which have a vast influence for good or evil in the economy of the world. These micro-organisms, the latest contribution to our knowledge of air, perform great analytical functions in organic nature, and are the means of converting much of its potential energy into actual energy. Through their action on dead matter the mutual dependence of plants and animals is secured, so that the air becomes at once the grave of organic death and the cradle of organic life. No doubt the ancients suspected this without being able to prove the dependence. Euripides seems to have seen it deductively when he describes the results of decay:—

> Then that which springs from earth, to earth returns,
> And that which draws its being from the sky
> Rises again up to the skyey height

The consequences of the progressive discoveries have added largely to our knowledge of life, and have given a marvellous development to the industrial arts. Combustion and respiration govern a wide range of processes. The economical use of fuel, the growth of plants, the food of animals, the processes of husbandry, the maintenance of public health, the origin and cure of disease, the production of alcoholic drinks, the processes of making vinegar and saltpetre—all these and many other kinds of knowledge have been brought under the dominion of law. No doubt animals respired, fuel burned, plants grew, sugar fermented, before we knew how they depended upon air. But as the knowledge was empirical, it could not be intelligently directed. Now all these processes are ranged in order under a wise economy of Nature, and can be directed to the utilities of life; for it is true, as Swedenborg says, that 'human ends always ascend as Nature descends.' There is scarcely a large industry in the world which has not received a mighty impulse by the better knowledge of air acquired within a hundred years. If I had time I could show still more strikingly the industrial advantages which have followed from Cavendish's discovery of the composition of water. I wish that I could have done this, because it was Addison who foolishly said, and Paley who as unwisely approved the remark, 'that mankind required to know no more about water than the temperature at which it froze and boiled, and the mode of making steam.'

When we examine the order of progress in the arts, even before they are illumined by science, their improvements seem to be the resultants of three conditions.

1. The substitution of natural forces for brute animal power, as when Hercules used the waters of the Alpheus to cleanse the Augean stables; or when a Kamchadal of Eastern Asia, who has been three years hollowing out a canoe, finds that he can do it in a few hours by fire.

2. The economy of time, as when a calendering machine produces the same gloss to miles of calico that an African savage gives to a few inches by rubbing it with the shell of a snail; or the economy of production, as when steel pens, sold when first introduced at one shilling apiece, are now sold at a penny per dozen; or when steel rails, lately costing 45*l.* per ton, can now be sold at 5*l.*

3. Methods of utilising waste products, or of endowing them with properties which render them of increased value to industry, as when waste scrap iron and the galls on the oak are converted into ink; or the badly-smelling waste of gasworks is transformed into fragrant essences, brilliant dyes, and fertilising manure; or when the effete matter of animals or old bones is changed into lucifer-matches.

All three results are often combined when a single end is obtained—at all events, economy of time and production invariably follows when natural forces substitute brute animal force. In industrial progress the sweat of the brow is lessened by the conceptions of the brain. How

exultant is the old Greek poet, Antipater,[1] when women are relieved of the drudgery of turning the grindstones for the daily supply of corn. 'Woman! you who have hitherto had to grind corn, let your arms rest for the future. It is no longer for you that the birds announce by their songs the dawn of the morning. Ceres has ordered the *water-nymphs* to move the heavy millstones and perform your labour.' Penelope had twelve slaves to grind corn for her small household. During the most prosperous time of Athens it was estimated that there were twenty slaves to each free citizen. Slaves are mere machines, and machines neither invent nor discover. The bondmen of the Jews, the helots of Sparta, the captive slaves of Rome, the serfs of Europe, and uneducated labourers of the present day who are the slaves of ignorance have added nothing to human progress. But as natural forces substitute and become cheaper than slave labour, liberty follows advancing civilisation. Machines require educated superintendence. One shoe factory in Boston by its machines does the work of thirty thousand shoemakers in Paris who have still to go through the weary drudgery of mechanical labour. The steam power of the world, during the last twenty years, has risen from $11\frac{1}{2}$ million to 29 million horse-power, or 152 per cent.

Let me take a single example of how even a petty manufacture improved by the teachings of science affects the comforts and enlarges the resources of mankind. When I was a boy, the only way of obtaining a light was by the tinder-box, with its quadruple materials, flint and steel, burnt rags or tinder, and a sulphur-match. If everything went well, if the box could be found and the air was dry, a light could be obtained in two minutes; but very often the time occupied was much longer, and the process became a great trial to the serenity of temper. The consequence of this was that a fire or a burning lamp was kept alight through the day. Old Gerard, in his Herbal, tells us how certain fungi were used to carry fire from one part of the country to the other. The tinder-box long held its position as a great discovery in the arts. The *Pyxidicula Igniaria* of the Romans appears to have been much the same implement as, though a little ruder than, the flint and steel which Philip the Good put into the collar of the Golden Fleece in 1429 as a representation of high knowledge in the progress of the arts. It continued to prevail till 1833, when phosphorus-matches were introduced; though I have been amused to find that there are a few venerable ancients in London who still stick to the tinder-box, and for whom a few shops keep a small supply. Phosphorus was no new discovery, for it had been obtained by an Arabian called Bechel in the eighth century. However, it was forgotten, and was rediscovered by Brandt, who made it out of very stinking materials in 1669. Other discoveries had, however, to be made before it could be used for lucifer-matches. The science of combustion was only developed on the discovery of oxygen a century later. Time had to elapse before chemical analysis showed the kind of bodies

[1] *Analecta Veterum Græcorum*, Epig. 39, vol. ii. p. 119.

which could be added to phosphorus so as to make it ignite readily. So it was not till 1833 that matches became a partial success. Intolerably bad they then were, dangerously inflammable, horribly poisonous to the makers and injurious to the lungs of the consumers. It required another discovery by Schrötter in 1845 to change poisonous waxy into innocuous red-brick phosphorus in order that these defects might be remedied, and to give us the safety-match of the present day. Now what have these successive discoveries in science done for the nation, in this single manufacture, by an economy of time? If before 1833 we had made the same demands for light that we now do, when we daily consume eight matches per head of the population, the tinder-box could have supplied the demand under the most favourable conditions by an expenditure of one quarter of an hour. The lucifer-match supplies a light in fifteen seconds on each occasion, or in two minutes for the whole day. Putting these differences into a year, the venerable ancient who still sticks to his tinder-box would require to spend ninety hours yearly in the production of light, while the user of lucifer-matches spends twelve hours; so that the latter has an economy of seventy-eight hours yearly, or about ten working days. Measured by cost of production at one shilling and sixpence daily, the economy of time represented in money to our population is twenty-six millions of pounds annually. This is a curious instance of the manner in which science leads to economy of time and wealth even in a small manufacture. In larger industries the economy of time and labour produced by the application of scientific discoveries is beyond all measurement. Thus the discovery of latent heat by Black led to the inventions of Watt; while that of the mechanical equivalent of heat by Joule has been the basis of the progressive improvements in the steam-engine which enables power to be obtained by a consumption of fuel less than one-fourth the amount used twenty years ago. It may be that the engines of Watt and Stephenson will yield in their turn to more economical motors; still they have already expanded the wealth, resources, and even the territories of England more than all the battles fought by her soldiers or all the treaties negotiated by her diplomatists.

The coal which has hitherto been the chief source of power probably represents the product of five or six million years during which the sun shone upon the plants of the Carboniferous Period, and stored up its energy in this convenient form. But we are using this conserved force wastefully and prodigally; for, although horse-power in steam engines has so largely increased since 1864, two men only now produce what three men did at that date. It is only three hundred years since we became a manufacturing country. According to Professor Dewar, in less than two hundred years more the coal of this country will be wholly exhausted, and in half that time will be difficult to procure. Our not very distant descendants will have to face the problem—What will be the condition of England without coal? The answer to that question depends upon the intellectual development of the nation at that time. The value of the in-

tellectual factor of production is continually increasing; while the values of raw material and fuel are lessening factors. It may be that when the dreaded time of exhausted fuel has arrived, its importation from other coal-fields, such as those of New South Wales, will be so easy and cheap that the increased technical education of our operatives may largely overbalance the disadvantages of increased cost in fuel. But this supposes that future Governments in England will have more enlightened views as to the value of science than past Governments have possessed.

Industrial applications are but the overflowings of science welling over from the fulness of its measure. Few would ask now, as was constantly done a few years ago, 'What is the use of an abstract discovery in science?' Faraday once answered this question by another, 'What is the use of a baby?' Yet round that baby centre all the hopes and sentiments of his parents, and even the interests of the State, which interferes in its upbringing so as to ensure it being a capable citizen. The processes of mind which produce a discovery or an invention are rarely associated in the same person, for while the discoverer seeks to explain causes and the relations of phenomena, the inventor aims at producing new effects, or at least of obtaining them in a novel and efficient way. In this the inventor may sometimes succeed without much knowledge of science, though his labours are infinitely more productive when he understands the causes of the effects which he desires to produce.

A nation in its industrial progress, when the competition of the world is keen, cannot stand still. Three conditions only are possible for it. It may go forward, retrograde, or perish. Its extinction as a great nation follows its neglect of higher education, for, as described in the proverb of Solomon, 'They that hate instruction love death.' In sociology, as in biology, there are three states. The first of balance, when things grow neither better nor worse; the second that of elaboration or evolution, as we see it when animals adapt themselves to their environments; and the third, that of degeneration, when they rapidly lose the ground they have made. For a nation, a state of balance is only possible in the early stage of its existence, but it is impossible when its environments are constantly changing.

The possession of the raw materials of industry and the existence of a surplus population are important factors for the growth of manufactures in the early history of a nation, but afterwards they are bound up with another factor—the application of intellect to their development. England could not be called a manufacturing nation till the Elizabethan age. No doubt coal, iron, and wool were in abundance, though, in the reign of the Plantagenets, they produced little prosperity. Wool was sent to Flanders to be manufactured, for England then stood to Holland as Australia now does to Yorkshire. The political crimes of Spain from the reign of Ferdinand and Isabella to that of Philip III. destroyed it as a great manufacturing nation, and indirectly led to England taking its position. Spain, through the activity and science of the Arabian intellect,

had acquired many important industries. The Moors and the Moriscoes, who had been in Spain for a period as long as from the Norman Conquest of this country to the present date, were banished, and with them departed the intellect of Spain. Then the invasion of the Low Countries by Philip II. drove the Flemish manufacturers to England, while the French persecution of the Huguenots added new manufacturing experience, and with them came the industries of cotton, wool, and silk. Cotton mixed with linen and wool became freely used, but it was only from 1738 to the end of the century that the inventions of Wyatt, Arkwright, Hargreaves, Crompton, and Cartwright started the wonderful modern development. The raw cotton was imported from India or America, but that fact as regards cost was a small factor in comparison with the intellect required to convert it into a utility. Science has in the last hundred years altered altogether the old conditions of industrial competition. She has taught the rigid metals to convey and record our thoughts even to the most distant lands, and, within less limits, to reproduce our speech. This marvellous application of electricity has diminished the cares and responsibilities of Governments, while it has at the same time altered the whole practice of commerce. To England steam and electricity have been of incalculable advantage. The ocean, which once made the country insular and isolated, is now the very life-blood of England and of the greater England beyond the seas. As in the human body the blood bathes all its parts, and through its travelling corpuscles carries force to all its members, so in the body politic of England and its pelagic extensions, steam has become the circulatory and electricity the nervous system. The colonies, being young countries, value their raw materials as their chief sources of wealth. When they become older they will discover it is not in these, but in the culture of scientific intellect, that their future prosperity depends. Older nations recognise this as the law of progress more than we do; or, as Jules Simon tersely puts it—'That nation which most educates her people will become the greatest nation, if not to-day, certainly to-morrow.' Higher education is the condition of higher prosperity, and the nation which neglects to develop the intellectual factor of production must degenerate, for it cannot stand still. If we felt compelled to adopt the test of science given by Comte, that its value must be measured by fecundity, it might be prudent to claim industrial inventions as the immediate fruit of the tree of science, though only fruit which the prolific tree has shed. But the test is untrue in the sense indicated, or rather the fruit, according to the simile of Bacon, is like the golden apples which Aphrodite gave to the suitor of Atalanta, who lagged in her course by stooping to pick them up, and so lost the race. The true cultivators of the tree of science must seek their own reward by seeing it flourish, and let others devote their attention to the possible practical advantages which may result from their labours.

There is, however, one intimate connection between science and industry which I hope will be more intimate as scientific education becomes

more prevalent in our schools and universities. Abstract science depends on the support of men of leisure, either themselves possessing or having provided for them the means of living without entering into the pursuits of active industry. The pursuit of science requires a superfluity of wealth in a community beyond the needs of ordinary life. Such superfluity is also necessary for art, though a picture or a statue is a saleable commodity, while an abstract discovery in science has no immediate or, as regards the discoverer, proximate commercial value. In Greece, when philosophical and scientific speculation was at its highest point, and when education was conducted in its own vernacular and not through dead languages, science, industry, and commerce were actively prosperous. Corinth carried on the manufactures of Birmingham and Sheffield, while Athens combined those of Leeds, Staffordshire, and London, for it had woollen manufactures, potteries, gold and silver work, as well as shipbuilding. Their philosophers were the sons of burghers, and sometimes carried on the trades of their fathers. Thales was a travelling oil merchant, who brought back science as well as oil from Egypt. Solon and his great descendant Plato, as well as Zeno, were men of commerce. Socrates was a stone-mason; Thucydides a gold-miner; Aristotle kept a druggist's shop until Alexander endowed him with the wealth of Asia. All but Socrates had a superfluity of wealth, and he was supported by that of others. Now if our universities and schools created that love of science which a broad education would surely inspire, our men of riches and leisure who advance the boundaries of scientific knowledge could not be counted on the fingers as they now are, when we think of Boyle, Cavendish, Napier, Lyell, Murchison, and Darwin, but would be as numerous as our statesmen and orators. Statesmen, without a following of the people who share their views and back their work, would be feeble indeed. But while England has never lacked leaders in science, they have too few followers to risk a rapid march. We might create an army to support our generals in science, as Germany has done, and as France is now doing, if education in this country would only mould itself to the needs of a scientific age. It is with this feeling that Horace Mann wrote:—'The action of the mind is like the action of fire; one billet of wood will hardly burn alone, though as dry as the sun and north-west wind can make it, and though placed in a current of air; ten such billets will burn well together, but a hundred will create a heat fifty times as intense as ten—will make a current of air to fan their own flame, and consume even greenness itself.'

VI. *Abstract Science the Condition for Progress.*

The subject of my address has been the relations of science to the public weal. That is a very old subject to select for the year 1885. I began it by quoting the words of an illustrious prince, the consort of our Queen, who addressed us on the same subject from this platform twenty-six years ago. But he was not the first prince who saw how closely science

is bound up with the welfare of States. Ali, the son-in-law of Mahomet, the fourth successor to the Caliphate, urged upon his followers that men of science and their disciples give security to human progress. Ali loved to say, 'Eminence in science is the highest of honours,' and 'He dies not who gives life to learning.' In addressing you upon texts such as these, my purpose was to show how unwise it is for England to lag in the onward march of science when most other European Powers are using the resources of their States to promote higher education and to advance the boundaries of knowledge. English Governments alone fail to grasp the fact that the competition of the world has become a competition in intellect. Much of this indifference is due to our systems of education. I have ill fulfilled my purpose if, in claiming for science a larger share in public education, I have in any way depreciated literature, art, or philosophy, for every subject which adds to culture aids in human development. I only contend that in public education there should be a free play to the scientific faculty, so that the youths who possess it should learn the richness of their possession during the educative process. The same faculties which make a man great in any walk of life—strong love of truth, high imagination tempered by judgment, a vivid memory which can co-ordinate other facts with those under immediate consideration—all these are qualities which the poet, the philosopher, the man of literature, and the man of science equally require and should cultivate through all parts of their education as well as in their future careers. My contention is that science should not be practically shut out from the view of a youth while his education is in progress, for the public weal requires that a large number of scientific men should belong to the community. This is necessary because science has impressed its character upon the age in which we live, and as science is not stationary but progressive, men are required to advance its boundaries, acting as pioneers in the onward march of States. Human progress is so identified with scientific thought, both in its conception and realisation, that it seems as if they were alternative terms in the history of civilisation. In literature, and even in art, a standard of excellence has been attained which we are content to imitate because we have been unable to surpass. But there is no such standard in science. Formerly, when the dark cloud was being dissipated which had obscured the learning of Greece and Rome, the diffusion of literature or the discovery of lost authors had a marked influence on advancing civilisation. Now, a Chrysoloras might teach Greek in the Italian universities without hastening sensibly the onward march of Italy; a Poggio might discover copies of Lucretius and Quintilian without exercising a tithe of the influence on modern life that an invention by Stephenson or Wheatstone would produce. Nevertheless, the divorce of culture and science, which the present state of education in this country tends to produce, is deeply to be deplored, because a cultured intelligence adds greatly to the development of the scientific faculty. My argument is that no amount of learning without science suffices in the present state

of the world to put us in a position which will enable England to keep ahead or even on a level with foreign nations as regards knowledge and its applications to the utilities of life. Take the example of any man of learning, and see how soon the direct consequences resulting from his learning disappear in the life of a nation, while the discoveries of a man of science remain productive amid all the shocks of empire. As I am in Aberdeen I remember that the learned Dutchman Erasmus was introduced to England by the encouragement which he received from Hector Boece, the Principal of King's College in this University. Yet even in the case of Erasmus—who taught Greek at Cambridge and did so much for the revival of classical literature as well as in the promotion of spiritual freedom—how little has civilisation to ascribe to him in comparison with the discoveries of two other Cambridge men, Newton and Cavendish. The discoveries of Newton will influence the destinies of mankind to the end of the world. When he established the laws by which the motions of the great masses of matter in the universe are governed, he conferred an incalculable benefit upon the intellectual development of the human race. No great discovery flashes upon the world at once, and therefore Pope's lines on Newton are only a poetic fancy :—

> Nature and Nature's laws lay hid in night,
> God said, 'Let Newton be,' and all was light.

No doubt the road upon which he travelled had been long in preparation by other men. The exact observations of Tycho Brahe, coupled with the discoveries of Copernicus, Kepler, and Galileo, had already broken down the authority of Aristotle and weakened that of the Church. But though the conceptions of the universe were thus broadened, mankind had not yet rid themselves of the idea that the powers of the universe were still regulated by spirits or special providences. Even Kepler moved the planets by spirits, and it took some time to knock these celestial steersmen on the head. Descartes, who really did so much by his writings to force the conclusion that the planetary movements should be dealt with as an ordinary problem in mechanics, looked upon the universe as a machine, the wheels of which were kept in motion by the unceasing exercise of a divine power. Yet such theories were only an attempt to regulate the universe by celestial intelligences like our own, and by standards within our reach. It required the discovery of an all-pervading law, universal throughout all space, to enlarge the thoughts of men, and one which, while it widened the conceptions of the universe, reduced the earth and solar system to true dimensions. It is by the investigation of the finite on all sides that we obtain a higher conception of the infinite—

> Willst du ins Unendliche schreiten,
> Geh nur im Endlichen nach allen Seiten.

Ecclesiastical authority had been already undermined by earnest inquirers such as Wycliffe and Huss before Luther shook the pillars of the Vatican.

They were removers of abuses, but were confined within the circles of their own beliefs. Newton's discovery cast men's minds into an entirely new mould, and levelled many barriers to human progress. This intellectual result was vastly more important than the practical advantages of the discovery. It is true that navigation and commerce mightily benefited by our better knowledge of the motions of the heavenly bodies. Still, these benefits to humanity are incomparably less in the history of progress than the expansion of the human intellect which followed the withdrawal of the cramps that confined it. Truth was now able to discard authority, and marched forward without hindrance. Before this point was reached Bruno had been burned, Galileo had abjured, and both Copernicus and Descartes had kept back their writings for fear of offending the Church.

The recent acceptance of evolution in biology has had a like effect in producing a far profounder intellectual change in human thought than any mere impulse of industrial development. Already its application to sociology and education is recognised, but that is of less import to human progress than the broadening of our views of Nature.

Abstract discovery in science is then the true foundation upon which the superstructure of modern civilisation is built; and the man who would take part in it should study science, and, if he can, advance it for its own sake and not for its applications. Ignorance may walk in the path lighted by advancing knowledge, but she is unable to follow when science passes her; for, like the foolish virgin, she has no oil in her lamp.

An established truth in science is like the constitution of an atom in matter—something so fixed in the order of things that it has become independent of further dangers in the struggle for existence. The sum of such truths forms the intellectual treasure which descends to each generation in hereditary succession. Though the discoverer of a new truth is a benefactor to humanity, he can give little to futurity in comparison with the wealth of knowledge which he inherited from the past. We, in our generation, should appreciate and use our great possessions—

For me your tributary stores combine,
Creation's heir; the world, the world is mine.

STATE OF SCIENCE.

REPORTS

ON THE

STATE OF SCIENCE.

Report of the Committee, consisting of Professor G. CAREY FOSTER, Sir W. THOMSON, Professor AYRTON, Professor J. PERRY, Professor W. G. ADAMS, Lord RAYLEIGH, Dr. O. J. LODGE, Dr. JOHN HOPKINSON, Dr. A. MUIRHEAD, Mr. W. H. PREECE, Mr. H. TAYLOR, Professor EVERETT, Professor SCHUSTER, Dr. J. A. FLEMING, Professor G. F. FITZGERALD, Mr. R. T. GLAZEBROOK (*Secretary*), Professor CHRYSTAL, Mr. H. TOMLINSON, *and* Professor W. GARNETT, *appointed for the purpose of constructing and issuing practical Standards for use in Electrical Measurements.*

THE Committee report that during the year the standards of resistance, in terms of the legal ohm referred to in the last Report, have been constructed, and their values determined in accordance with the resolution adopted on June 25, 1884.

The one-ohm standards were generally referred to the original B.A. units of the Association by combining in multiple arc with the standard one of the 100 B.A. units, and determining by Carey Foster's method the difference between the combination and a B.A. unit, and then assuming, in accordance with the resolution, that 1 B.A. unit = ·9889 legal ohm.

The following values were thus found for the two standards.

The temperatures were taken by a thermometer graduated to tenths of a degree centigrade, which had been compared with the Kew standards.

Resistance Coil, Elliott, No. 139, Ω 100.

Date	Temperature	Resistance
Nov. 24, 1884	11°·4	·99878
„ 26, „	11°·6	·99890
„ 27, „	12°·9	·99916
„ 28, „	13°·5	·99930
Dec. 5, „	13°·5	·99931
„ 12, „	15°·3	·99979
July 30, 1885 . . .	17°·2	1·00027
„ 28, „	18°·1	1·00061

Mean value . . . . . . ·999515, at 14°·1 C.
Temperature coefficient . . ·000271

Resistance Coil, Elliott, No. 140, B.A. 101.

Date	Temperature	Resistance
Nov. 24, 1884 . . .	11°·4	·99813
„ 25, „ . . .	11°·5	·99815

July 30, 1885 . . .	17°·2	·99961
„ 29, „ . . .	18°·0	·99983

Mean value . . . . . . ·998815, at 14°·1 C.
Temperature coefficient . . ·000259

The ten-ohm standards were then compared with the one-ohm by means of the arrangement suggested by Lord Rayleigh, and described in the Report for 1883, and from these values were obtained for the coils of higher resistance.

The results are contained below.

No. of Coil	Resistance	Temperature

These experiments were carried out at the Cavendish Laboratory by the Secretary and Mr. H. Wilson, of St. John's College.

At the request of M. Mascart, the Secretary compared with the legal ohms of the Association three mercury copies of a legal ohm, constructed by M. J. R. Benoit, of Paris. A detailed account of these experiments was laid before the Physical Society.[1] The values found are given below.

No. of Tubes	Value found by M. J. R. Benoit	Value found by R. T. G.	Diff
37	1·00045	·99990	·00055
38	1·00066	1·00011	·00055

The Committee hope that arrangements may be made for issuing standards of electro-motive force and constructing standards of capacity. In conclusion, they would ask to be reappointed, with the addition of the names of Professor J. J. Thomson and Mr. W. N. Shaw, with the renewal of the unexpended grant of 50*l.*

Report of the Committee, consisting of Professors A. JOHNSON (*Secretary*), J. G. MACGREGOR, J. B. CHERRIMAN, H. T. BOVEY, *and* Mr. C. CARPMAEL, *appointed for the purpose of promoting Tidal Observations in Canada.*

THE Committee have represented to the Canadian Government the importance of publishing tide-tables for Canadian waters, and the necessity for this purpose of establishing stations for continuous tidal observations, recommending that the observations be subsequently reduced by the methods of the British Association.

They have pointed to the example of the United States Government, which has provided tide-tables for both the Atlantic and Pacific coasts.

In urging the practical side of the question they have more especially referred to the tide-tables for British and Irish ports published by the Admiralty, which give the rate and set of the tidal currents in the waters surrounding the British islands; and they have drawn attention to the heavy annual losses caused by ignorance of these currents in Canadian waters, as shown by the wreck list.

In order to strengthen their representation from this point of view, they deemed it well to get the opinions of Boards of Trade and shipowners and shipmasters. On inquiry it appeared that the Montreal Board of Trade were at the very time considering the question, which had been brought independently before them. On learning the object of the Committee they gave it their most hearty support, and addressed a strong memorial on the subject to the Dominion Government.

The Boards of Trade of the other chief ports of the Dominion also sent similar memorials. The shipowners and masters of ships, to whom application was made, were practically unanimous in their testimony as to the pressing need for knowledge on the subject.

The representations of your Committee were made through the Minister of Marine, with whom an interview was obtained, at which a memorial was submitted. Copies of the answers of the shipmasters (a large number of which had been received) were submitted at the same time. Full explanations, in reply to the inquiries of the Minister, were given, more especially on practical points connected with the proposed observations at fixed stations and the reductions, for which your Committee are largely indebted to a corresponding committee appointed by the Council, consisting of the Right Hon. Sir Lyon Playfair, Professor J. Couch Adams, Sir William Thomson, and Professor Darwin.

During the session of Parliament the Royal Society of Canada also addressed petitions to the Governor-General and the two Houses of Parliament, strongly urging the need of tidal observations.

The reply of the Minister of Marine stated that, owing to the large outlay on the Georgian Bay Survey, and on the expedition to Hudson's Bay during the past summer (1885), the Government did not propose to take action in the matter of tidal observations at present. This unfavourable answer, it will be observed, is made to depend on a temporary financial condition, and your Committee have reason to believe that if the financial prospects improve by next session of Parliament, the Government will take the matter into earnest consideration; they therefore suggest that the Committee be reappointed.

Fifth Report of the Committee, consisting of Mr. JOHN MURRAY (*Secretary*), Professor SCHUSTER, Professor Sir WILLIAM THOMSON, Professor Sir H. E. ROSCOE, Professor A. S. HERSCHEL, Captain W. DE W. ABNEY, Professor BONNEY, Mr. R. H. SCOTT, *and* Dr. J. H. GLADSTONE, *appointed for the purpose of investigating the practicability of collecting and identifying Meteoric Dust, and of considering the question of undertaking regular observations in various localities.*

THE Secretary reported that collecting apparatus had been sent to various oceanic islands, and that a report would be prepared by next year on the specimens received.

Third Report of the Committee, consisting of Professors G. H. Darwin *and* J. C. Adams, *for the Harmonic Analysis of Tidal Observations. Drawn up by* Professor G. H. Darwin.

I. Record of Work during the past Year.

The edition of the computation forms referred to in the second report is now completed, and copies are on sale with the Cambridge Scientific Instrument Company, St. Tibbs' Row, Cambridge, at the price of 2*s.* 6*d.* each. Some copies of the first report, in which the theory and use of these forms are explained, are also on sale at the same price. A few copies of the computation forms have been sent to the librarians of some of the principal Scientific Academies of Europe and America.[1]

In South Africa, Mr. Gill, at the Cape, and Mr. Neison, at Natal, are now engaged in reducing observations with forms supplied from this edition.

A memorial has been addressed to the Government of the Dominion of Canada, urging the desirability of systematic tidal observation, and the publication of tide-tables for the Canadian coasts. There seems to be good hope that a number of tide-gauges will shortly be set up on the Atlantic and Pacific coasts, and in the Gulf of the St. Lawrence. The observations will probably be reduced according to the methods of the British Association, and the predictions made with the instrument of the Indian Government.

Major Baird has completed the reduction of all the tidal results obtained at the Indian stations to the standard form proposed in the Report of 1883, and Mr. Roberts has similarly reduced a few results read before the Association by Sir William Thomson and Captain Evans in 1878. All these are now being published in the 'Proceedings of the Royal Society,' in a paper by Major Baird and myself.

A large number of tidal results have been obtained by the United States Coast Survey, and reduced under the superintendence of Professor Ferrel. Although the method pursued by him has been slightly different from that of the British Association, it appears that the American results should be comparable with those at the Indian and European ports. Professor Ferrel has given an assurance that this is the case; nevertheless, there appears to be strong internal evidence that, at some of the ports, some of the phases should be altered by 180°. The doubt thus raised will probably be removed, and the paper before the Royal Society will afford a table of reference for all—or nearly all—the results of the harmonic method up to the date of its publication.

The manual of tidal observation promised by Major Baird is now completed, and will be published shortly. This work will explain fully all the practical difficulties likely to be encountered in the choice of a station for a tide-gauge, and in the erection and working of the instrument. Major Baird's great experience in India, and the success with which the operations of which he has had charge have been carried out, render his

[1] Namely, the Royal Societies of London and Edinburgh, the Royal Irish Academy, the Academies of Paris, Berlin, and Vienna, the United Coast Survey, and the Cambridge Philosophical Society.

advice of great value for the prosecution of tidal observation in other countries. The work also explains the method of measuring the tide diagrams, entering the figures in the computation forms, and the subsequent numerical operations.

II. Certain Factors and Angles used in the Reduction of Tidal Observations.

In completing the reduction of the results of harmonic analysis to the standard form, a number of angles and factors are required which depend on the longitude of the moon's node. Tables of these angles and factors have been computed under the superintendence of Major Baird.[1] It may happen, however, that the tables are inaccessible to the computer, and the computation from the full formulæ might be somewhat laborious. It happens that the angles ν, ξ, ν', $2\nu''$ (the meanings of which are explained in the Report of 1883) are all expressible in the form

$$\text{A} \sin N + \text{B} \sin 2N + \text{C} \sin 3N + \ldots\ldots,$$

where N is the longitude of the moon's node, and that the coefficients diminish with such rapidity that the first two terms are probably sufficient for all practical purposes.

Also the several factors f are reducible to the form

$$\text{A} + \text{B} \cos N + \text{C} \cos 2N + \ldots\ldots,$$

and three terms are practically sufficient.

I have obtained the approximate formulæ given below in this form. The rigorous results having been tabulated, it appeared easier to work from them instead of from analytical expressions in terms of the longitude of the moon's node. I find, then, the following results:—

Schedule I. *Approximate Formulæ for Angles.*

$$\nu = 12^\circ{\cdot}9 \sin N - 1^\circ{\cdot}3 \sin 2N,$$

$$\xi = \nu - 1^\circ{\cdot}07 \sin N,$$

$$(\text{for } K_1) \quad \nu' = 8^\circ{\cdot}8 \sin N - 0^\circ{\cdot}6 \sin 2N,$$

$$(\text{for } K_2) \quad 2\nu'' = 17^\circ{\cdot}8 \sin N - 0^\circ{\cdot}5 \sin 2N.$$

Also $\Delta = 16^\circ{\cdot}51 + 3^\circ{\cdot}44 \cos N - 0^\circ{\cdot}19 \cos 2N$, and $\Delta_{,} = 16^\circ{\cdot}36$.

For the meanings of Δ and $\Delta_{,}$ the reader must refer to Part IV.

Approximate Formulæ for Factors f.

For M_2 and other tides,

$$\text{f} = \frac{\cos^4 \frac{1}{2} I}{\cos^4 \frac{1}{2}\omega \cos^4 \frac{1}{2} i} = 1{\cdot}0003 - {\cdot}0373 \cos N + {\cdot}0002 \cos 2N.$$

For O, $\text{f} = \dfrac{\sin I \cos^2 \frac{1}{2} I}{\sin \omega \cos^2 \frac{1}{2}\omega \cos^4 \frac{1}{2} i} = 1{\cdot}0088 + {\cdot}1886 \cos N - {\cdot}0146 \cos 2N.$

For K_2 . . . . $\text{f} = 1{\cdot}0243 + {\cdot}2847 \cos N + {\cdot}0080 \cos 2N.$

For K_1 . . . . $\text{f} = 1{\cdot}0060 + {\cdot}1156 \cos N - {\cdot}0088 \cos 2N.$

For Mf . . $\text{f} = \dfrac{\sin^2 I}{\sin^2 \omega \cos^4 \frac{1}{2} i} = 1{\cdot}0429 + {\cdot}4135 \cos N - {\cdot}0040 \cos 2N.$

[1] Some of these are given in the Report of 1883.

For Mm,

$$f=\frac{1-\frac{3}{2}\sin^2 I}{(1-\frac{3}{2}\sin^2\omega)(1-\frac{3}{2}\sin^2 i)}=1{\cdot}0000-{\cdot}1299\cos N+{\cdot}0013\cos 2N.$$

Even if all the terms in $2N$ were omitted, the approximations might be good enough for all practical purposes.

III. On the Periods chosen for Harmonic Analysis in the Computation Forms.

Before proceeding to the subject of this section, it may be remarked that it is unfortunate that the days of the year in the computation forms should have been numbered from unity upwards, instead of from zero, as in the case of the hours. It would have been preferable that the first entry should have been numbered Day 0, Hour 0, instead of Day 1, Hour 0. This may be rectified with advantage if ever a new issue of the forms is required, but the existing notation is adhered to in this section.

The computation form for each tide consists of pages for entry of the hourly tide-heights, in which the entries are grouped according to rules appropriate to that tide. The forms terminate with a broken number of hours. This, as we shall now show, is erroneous, although this error may not be of much practical importance.

In § 9 of the Report for 1883 the following passage occurs :—

'The elimination of the effects of the other tides may be improved by choosing the period for analysis not exactly equal to one year. For suppose that the expression for the height of water is

$$A_1\cos n_1t+B_1\sin n_1t+A_2\cos n_2t+B_2\sin n_2t \quad . \quad . \quad . \quad (61)$$

'where n_2 is nearly equal to n_1, and that we wish to eliminate the n_2-tide, so as to be left only with the n_1-tide.

'Now, this expression is equal to

$$\left.\begin{array}{l}\{A_1+A_2\cos(n_1-n_2)t-B_2\sin(n_1-n_2)t\}\cos n_1t\\ +\{B_1+A_2\sin(n_1-n_2)t+B_2\cos(n_1-n_2)t\}\sin n_1t\end{array}\right\} \quad . \quad . \quad (62)$$

'That is to say, we may regard the tide as oscillating with a speed n_1, but with slowly varying range.'

Although this is thus far correct, yet the subsequent justification of the plan according to which the computation forms have been compiled is wrong.

In the column appertaining to any hour in the form we have n_1t a multiple of 15°, if n_1 be a diurnal, and of 30°, if n_1 be a semidiurnal tide.

Consider the column headed 'p-hours'; then $n_1t=15°p$ for diurnals, and $30°p$ for semidiurnals.

Hence (62), quoted above, shows us that, for diurnal tides, the sum of all the entries (of which suppose there are q) in the column numbered p-hours, is

$$\cos 15^\circ p\{A_1 q + A_2\Big[\cos(n_1-n_2)\frac{15p}{n_1} + \cos[(n_1-n_2)\Big(\frac{2\pi}{n_1}+\frac{15p}{n_1}\Big)]$$
$$+\cos[(n_1-n_2)\Big(2\frac{2\pi}{n_1}+\frac{15p}{n_1}\Big)] + \ldots\Big] + B_2[\&c.]\} + \sin 15^\circ p\ \{\&c.\} \quad (a)$$

And for semidiurnal tides the arguments of all the circular functions in (a) are to be doubled.

Now, we want to choose such a number of terms that the series by which A_2 and B_2 are multiplied may vanish. This is the case if the series is exactly re-entrant, and is nearly the case if nearly re-entrant.

The condition is exactly satisfied for diurnal tides, if

$$(n_1-n_2)q\frac{2\pi}{n_1}=2\pi r,$$

where r is either a positive or negative integer. And for semidiurnal tides, if

$$(n_1-n_2)q\frac{4\pi}{n_1}=2\pi r.$$

That is to say,

$$(n_1-n_2)q=n_1 r, \text{ for diurnal tides,}$$

or

$$(n_1-n_2)q=\tfrac{1}{2}n_1 r, \text{ for semidiurnal tides.}$$

It is not worth while attempting to eliminate the effect of the semidiurnal tides on the diurnal tides, and *vice versâ*, because we cannot be more than a fraction of a day out, and on account of the incommensurability of the speeds we cannot help being wrong to that amount.

S *Series.*

Now suppose we are analysing for the S_2 tide, and wish to minimise the effect of the M_2 tide.

Then
$$n_1=2(\gamma-\eta)=2\times 15^\circ \text{ per hour,}$$
$$n_2=2(\gamma-\sigma),$$
$$n_1-n_2=2(\sigma-\eta)=1^\circ{\cdot}0158958 \text{ per hour.}$$

The equation is

$$1^\circ{\cdot}0158958q=15^\circ r.$$

If $r=25$, $q=369{\cdot}13$.

Thus 25 periods of $2(\sigma-\eta)$ is $369{\cdot}13$ mean solar days. It follows, therefore, that we must sum the series over 369 days in order to be as near right as possible.

Now this is equally true of all the columns, and each should have 369 entries.

Hence, in order to have 369 entries in each column, the present S_2 computation form should have the last three entries cut off. The divisors are to be, of course, changed accordingly.

M *Series.*

Now consider that we are analysing for M_2, and wish to minimise the effect of the S_2 tide. Hence

$$n_1=2(\gamma-\sigma)=2\times 14^\circ{\cdot}4920521 \text{ per hour},$$
$$n_2=2(\gamma-\eta),$$
$$n_1-n_2=-1^\circ{\cdot}0158958 \text{ per hour}.$$

Hence, taking r negative, the equation is

$$1^\circ{\cdot}0158958q=14^\circ{\cdot}4920521r.$$

If $r=25$, $q=356{\cdot}63$.

Thus 25 periods of $2(\sigma-\eta)$ is 356·63 of mean lunar time.

It follows, therefore, that we must have 357 entries in each column.

Thus the M_2 computation form should have the row numbered 357 complete, adding 9 more entries.

There are no 'changes' amongst these 9 entries. The divisors are to be modified accordingly, here and in all subsequent cases.

K *Series.*

To minimise the effect of M_2 on K_2, we have

$$n_1=2\gamma=2\times 15^\circ{\cdot}0410686 \text{ per hour},$$
$$n_2=2(\gamma-\sigma),$$
$$n_1-n_2=2(\sigma-\eta)=1^\circ{\cdot}0158958 \text{ per hour}.$$
$$1^\circ{\cdot}0158958q=15^\circ{\cdot}0410686r.$$

If $r=25$, $q=370{\cdot}14$.

Hence we should complete the row numbered 370.

The last 3 entries of the existing tables are to be cut off.

To minimise the effect of O on K_1, we have

$$n_1=\gamma=15^\circ{\cdot}0410686 \text{ per hour},$$
$$n_2=\gamma-2\sigma,$$
$$n_1-n_2=2\sigma=1^\circ{\cdot}0980330 \text{ per hour}.$$
$$1^\circ{\cdot}0980330q=15^\circ{\cdot}0410686r.$$

If $r=27$, $q=369{\cdot}85$.

Thus $q=370$ again gives the best result, and confirms the conclusion from the above.

The N *Series.*

Here $$n_1=2\gamma-3\sigma+\varpi=2\times 14^\circ{\cdot}2198648 \text{ per hour}.$$

To minimise the effect of M_2,

$$n_2=2\gamma-2\sigma,$$
$$n_1-n_2=(\sigma-\varpi)=-0^\circ{\cdot}5443747 \text{ per hour}.$$
$$0{\cdot}5443747q=14^\circ{\cdot}2198648r.$$

If $r=13$, $q=339{\cdot}58$.

Hence we should complete the row numbered 340.

There is no justification for the alternative offered in the computation forms of continuing the entries up to $369^{\mathrm{d}}\ 3^{\mathrm{h}}$ of mean solar time.

The L *Series.*

Here $$n_1=2\gamma-\sigma-\varpi=2\times 14^\circ{\cdot}7642394 \text{ per hour}.$$

To minimise the effect of M_2,

$$n_2=2\gamma-2\sigma,$$
$$n_1-n_2=\sigma-\varpi=0^\circ{\cdot}5443747 \text{ per hour.}$$
$$0{\cdot}5443747q=14^\circ{\cdot}7642394r.$$

If $r=13$, $q=352{\cdot}58$.

Hence we should complete the row numbered 353.

There is no justification for the alternative offered in the computation forms of continuing the entries up to $369^d\ 3^h$ of mean solar time.

The ν Series.

Here $\quad n_1=2\gamma-3\sigma-\varpi+2\eta=2\times14^\circ{\cdot}2562915$ per hour.

To minimise the effect of M_2,

$$n_2=2\gamma-2\sigma,$$
$$n_1-n_2=-\sigma-\varpi+2\eta=-0^\circ{\cdot}4715211 \text{ per hour.}$$
$$0{\cdot}4715211q=14{\cdot}2562915r.$$

If $r=11$, $q=332{\cdot}6$.

Hence we should complete the row numbered 333.

There is no justification for the alternative offered in the computation forms of continuing the entries up to $369^d\ 3^h$ of mean solar time.

The λ Series.

Here $\quad n_1=2\gamma-\sigma+\varpi-2\eta=2\times14^\circ{\cdot}7278127$ per hour.

To minimise the effect of M_2,

$$n_2=2\gamma-2\sigma,$$
$$n_1-n_2=\sigma+\varpi-2\eta=0^\circ{\cdot}4715211 \text{ per hour.}$$
$$0{\cdot}4715211q=14{\cdot}7278127r.$$

If $r=11$, $q=343{\cdot}58$.

Hence we should complete the row numbered 344.

There is no justification for the alternative offered in the computation forms of continuing the entries up to $369^d\ 3^h$ of mean solar time.

The 2N Series.

Here $\quad n_1=2\gamma-4\sigma+2\varpi=2\times13^\circ{\cdot}9476774$ per hour.

To minimise the effect of M_2,

$$n_2=2\gamma-2\sigma,$$
$$n_1-n_2=-2(\sigma-\varpi)=1^\circ{\cdot}0887494 \text{ per hour.}$$
$$1{\cdot}0887494q=13{\cdot}9476774r.$$

If $r=26$, $q=333{\cdot}08$.

Hence we must complete the row numbered 333.

The T Series.

Here $\quad n_1=2\gamma-3\eta=2\times14^\circ{\cdot}9794657$ per hour.

To minimise the effect of M_2,

$$n_2=2\gamma-2\sigma,$$
$$n_1-n_2=2\sigma-3\eta=0^\circ{\cdot}9748272 \text{ per hour.}$$
$$0{\cdot}9748272q=14{\cdot}9794657r.$$

If $r=24$, $q=368{\cdot}79$.

Hence we must complete the row numbered 369.

The R *Series.*

Here $n_1=2\gamma-\eta=2\times15°\cdot0205343$ per hour.

To minimise the effect of M_2,

$$n_2=2\gamma-2\sigma,$$

$$n_1-n_2=2\sigma-\eta=1°\cdot0569644 \text{ per hour.}$$

$$1\cdot0569644q=15\cdot0205343r.$$

If $r=25$, $q=355\cdot28$, and $r=26$, $q=369\cdot49$.

Hence we should either complete the row numbered 355 or that numbered 369.

The 2MS *Series.*

Here $n_1=2\gamma-4\sigma+2\eta=2\times13°\cdot9841042$ per hour.

To minimise the effect of M_2,

$$n_2=2\gamma-2\sigma,$$

$$n_1-n_2=-2(\sigma-\eta)=-1°\cdot0158958 \text{ per hour.}$$

$$1\cdot0158958q=13\cdot9841042r.$$

If $r=24$, $q=330\cdot37$, and $r=25$, $q=344\cdot13$.

Hence we should either complete the row numbered 330 or that numbered 344.

The 2SM *Series.*

Here $n_1=2\gamma+2\sigma-4\eta=2\times15°\cdot5079479$ per hour.

To minimise the effect of M_2,

$$n_2=2\gamma-2\sigma,$$

$$n_1-n_2=4(\sigma-\eta)=2°\cdot0317916 \text{ per hour.}$$

$$2\cdot0317916q=15\cdot5079479r.$$

If $r=48$, $q=366\cdot37$.

Hence we should complete the row numbered 366.

The O *Series.*

Here $n_1=\gamma-2\sigma=13°\cdot9430356$ per hour.

To minimise the effect of K_1,

$$n_2=\gamma,$$

$$n_1-n_2=-2\sigma=-1°\cdot0980330 \text{ per hour.}$$

$$1\cdot0980330q=13\cdot9430356r.$$

If $r=27$, $q=342\cdot85$.

Hence we should complete the row numbered 343, cutting off the last three entries in the present forms.

The P *Series.*

Here $n_1=\gamma-2\eta=14°\cdot9589314$ per hour.

It is open to question whether it is best to minimise the effect of K_1 or of O.

For K_1 take $$n_2=\gamma,$$
$$n_1-n_2=-2\eta=-0^\circ{\cdot}0821372 \text{ per hour.}$$
$$0{\cdot}0821372q=14{\cdot}9589314r.$$
If $r=2$, $q=364{\cdot}24$.

Hence we should complete the row numbered 364.

For O, take $$n_2=\gamma-2\sigma,$$
$$n_1-n_2=2(\sigma-\eta)=1^\circ{\cdot}0158958 \text{ per hour.}$$
$$1{\cdot}0158958q=14{\cdot}9589314r.$$
If $r=25$, $q=368{\cdot}12$.

Hence we should complete the row numbered 368.

It is better to abide by this, for in the former case n_1-n_2 varies very slowly; and we may be satisfied that on stopping with row 368 the effects of O and K_1 will both be adequately eliminated.

The J Series.

Here $$n_1=\gamma+\sigma-\varpi=15^\circ{\cdot}5854433 \text{ per hour.}$$
To minimise the effect of K_1,
$$n_2=\gamma,$$
$$n_1-n_2=\sigma-\varpi=0^\circ{\cdot}5443747 \text{ per hour.}$$
$$0{\cdot}5443747q=15{\cdot}5854433r.$$
If $r=12$, $q=343{\cdot}56$, and $r=13$, $q=372{\cdot}19$.

To minimise the effect of O,
$$n_2=\gamma-2\sigma,$$
$$n_1-n_2=3\sigma-\varpi=1^\circ{\cdot}6424077 \text{ per hour.}$$
$$1{\cdot}6424077q=15{\cdot}5854433r.$$
If $r=36$, $q=341{\cdot}6$, and $r=39$, $q=370{\cdot}09$.

Since in the latter case n_1-n_2 varies three times as fast as in the former, it will be better to abide by this, and stop either with the row numbered 342 or that numbered 370.

The Q Series.

Here $$n_1=\gamma-3\sigma+\varpi=13^\circ{\cdot}3986609 \text{ per hour.}$$
To minimise the effect of K_1,
$$n_2=\gamma,$$
$$n_1-n_2=-(3\sigma-\varpi)=-1^\circ{\cdot}6424077 \text{ per hour.}$$
$$1{\cdot}6424077q=13{\cdot}3986609r.$$
If $r=38$, $q=310{\cdot}00$.

To minimise the effect of O,
$$n_2=\gamma-2\sigma,$$
$$n_1-n_2=-(\sigma-\varpi)=-0^\circ{\cdot}5443747 \text{ per hour.}$$
$$0{\cdot}5443747q=13{\cdot}3986609r.$$
If $r=12$, $q=307{\cdot}36$.

Since in the former case n_1-n_2 varies about three times as fast as in

the latter, it will be better to abide by the former, and stop with the row numbered 310.

With regard to the quaterdiurnal and terdiurnal tides, it does not signify where we stop; but it seems more reasonable to stop with the exact year of 365 mean solar days. These tides are called MS, MN, MK, 2MK.

Schedule II.

Periods over which the Harmonic Analysis should extend.

Initial of series	Number of day and hour of last entry in special time	Period elapsing from 0^h of special day 1 to 23^h of last special day in mean solar hours
S	369^d 23^h	368^d 23^h
M	357 23	369 11
K	370 23	368 23
N	340 23	358 15
L	353 23	358 14
ν	333 23	350 8
λ	344 23	350 8
2N	333 23	358 2
T	369 23	369 11
R	355 23 or 370 23	354 11 or 369 11
2MS	330 23 or 344 23	353 22 or 368 23
2SM	366 23	353 23
O	343 23	368 23
P	368 23	368 23
J	342 23 or 370 23	329 3 or 356 1
Q	310 23	347 0

In the second column the numbers are given to the nearest mean solar hour.

IV. A Comparison of the Harmonic Treatment of Tidal Observations with the Older Methods.

§ 1. *On the Method of Computing Tide-tables.*

There is nothing in the harmonic reduction of tidal observations which necessitates recourse to mechanical prediction of the tides. It may happen that it is desirable to produce a tide-table by arithmetical processes, and that the computers prefer to use the older methods of corrections, or it may be desired to obtain the tidal constants in the harmonic notation from older observations. For either of these purposes it is necessary to show how the harmonically expressed results may be converted into the older form, so that the constants for the fortnightly inequality in time and height, and the corrections for parallax and declination, may be obtained from those of the harmonic analysis, and conversely.

In the following sections I propose, therefore, first to reduce the harmonic presentment of the resultant tide into the synthetic form, where we have a single harmonic term depending on the local mean solar time of moon's transit, and on corrections depending on the R.A., declination, and parallax of the perturbing bodies. Subsequently it will be shown how a synthesis may be carried out more simply by retaining the mean longitudes and elements of the orbits.

§ 2. *Notation for Mean Heights and Retardations derived from the Harmonic Method.*

The notation of the Report of 1883 is adopted; and I shall carry the approximation to about the same degree as has been adopted by the older writers. Closer approximation may, of course, be easily obtained.

In the Report of 1883 the mean height[1] of a tide is denoted by H, and the retardation or lag by κ. In the present note it will be necessary to refer to several of the H's and κ's at the same time, and therefore it is expedient to introduce the following notation:—

Schedule III.

Initial of tide	Mean height (H)	Retardation (κ)	Initial of tide	Mean height (H)	Retardation (κ)
M_2	M	2μ	L	L	2λ
S_2	S	2ζ	T	T	2ζ
Lunar K_2	K''	2κ	R	R	2ζ
Solar K_2	$K_{\prime}''$	2κ	O	M'	μ'
K_2	K_2	2κ	P	S'	ζ'
N	N	2ν	K_1	K_1	κ_1

In this schedule we assume T and R (of speeds $2\gamma-3\eta$ and $2\gamma-\eta$) to have the same lag as S_2; and we use ν in a new sense, the old ν, the

[1] I use height to denote semi-range. All references to this Report will simply be by the date 1883.

R.A. of the intersection of the equator with the lunar orbit, being denoted by ν_0. The initials of each tide are used to denote its height at any time.

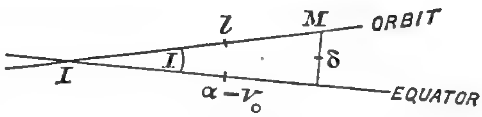
§ 3. *Introduction of Hour-angles, Parallaxes, and Declinations.*

We must now get rid of the elements of the orbit and of the mean longitudes, and introduce hour-angles, declinations, and parallaxes.

At the time t let α, δ, ψ be ☽'s R.A., and declination, and hour-angle.
and $\alpha_{\prime\prime}$, $\delta_{\prime\prime}$, $\psi_{\prime\prime}$, ☉'s R.A., and declination, and hour-angle.

Let l be ☽'s longitude in her orbit measured from 'the intersection,' and $\alpha-\nu_0$ (ν_0 being the ν of 1883) be ☽'s R.A. measured from the intersection.

The annexed figure exhibits the relation of the several angles to one another.



The spherical triangle affords the relations

$$\tan(\alpha-\nu_0)=\cos I\tan l,\quad \sin\delta=\sin I\sin l \quad . \quad . \quad . \quad . \quad (1)$$

From the first of (1) we have, approximately,

$$\alpha=l+\nu_0-\tan^2\tfrac{1}{2}I\sin 2l \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

Now, $s-\xi$ is the moon's mean longitude measured from I, and $s-p$ is the mean anomaly. Hence, approximately,

$$l=s-\xi+2e\sin(s-p) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

And therefore, approximately,

$$\alpha=s+\nu_0-\xi+2e\sin(s-p)-\tan^2\tfrac{1}{2}I\sin 2(s-\xi) \quad . \quad . \quad . \quad (4)$$

Now, $t+h$ being the sidereal hour-angle,

$$\psi=t+h-\alpha \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

Therefore, from (4) and (5),

$$t+h-s-(\nu_0-\xi)=\psi+2e\sin(s-p)-\tan^2\tfrac{1}{2}I\sin 2(s-\xi). \quad . \quad (6)$$

By the second of (1) we have, approximately,

$$\cos^2\delta=1-\tfrac{1}{2}\sin^2 I+\tfrac{1}{2}\sin^2 I\cos 2(s-\xi) \quad . \quad . \quad . \quad . \quad (7)$$

Hence, if Δ be such a declination that $\cos^2\Delta$ is the mean value of $\cos^2\delta$, we have

$$\left.\begin{aligned}\cos^2\Delta&=1-\tfrac{1}{2}\sin^2 I\\ \text{and }\cos^2\Delta_{\prime}&=1-\tfrac{1}{2}\sin^2\omega\end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (8)$$

From this we have (neglecting terms in $\sin^4\Delta$) the following relations:—

$$\cos^4\tfrac{1}{2}I=\cos^2\Delta,\quad \sin I\cos^2\tfrac{1}{2}I=\sqrt{2}\sin\Delta\cos\Delta,\quad \sin^2 I=2\sin^2\Delta,$$

$$\cos^4\tfrac{1}{2}\omega=\cos^2\Delta_{\prime},\quad \sin\omega\cos^2\tfrac{1}{2}\omega=\sqrt{2}\sin\omega\cos\omega,\quad \sin^2\omega=2\sin^2\Delta_{\prime}.$$

Thus we may put

$$\left.\begin{aligned} &\frac{\cos^4\frac{1}{2}I}{\cos^4\frac{1}{2}\omega\cos^4\frac{1}{2}i}=\frac{\cos^2\Delta}{\cos^2\Delta_{\prime}}, \qquad \frac{\sin I\cos^2\frac{1}{2}I}{\sin\omega\cos^2\frac{1}{2}\omega\cos^4\frac{1}{2}i}=\frac{\sin 2\Delta}{\sin 2\Delta_{\prime}} \\ &\frac{\sin^2 I}{\sin^2\omega(1-\frac{3}{2}\sin^2 i)}=\frac{\sin^2\Delta}{\sin^2\Delta_{\prime}}, \quad \tan^2\tfrac{1}{2}I=\tfrac{1}{2}\tan^2\Delta \end{aligned}\right\} \quad . \quad . \quad (9)$$

An approximate formula for Δ and the value of $\Delta_{\prime}$ are

$$\Delta=16^{\circ}\cdot 51+3^{\circ}\cdot 44\cos\mathrm{N}-0^{\circ}\cdot 19\cos 2\mathrm{N},\ \Delta_{\prime}=16^{\circ}\cdot 36 \quad . \quad . \quad (10)$$

The introduction of Δ and $\Delta_{\prime}$ in place of I and ω entails a loss of accuracy, and it is only here made because former writers have followed that plan. It may easily be dispensed with.

Now let us write

$$\left.\begin{aligned} D&=\cos 2(s-\xi), \qquad D'=\sin 2(s-\xi) \\ \Pi&=\cos(s-p), \qquad \Pi'=\sin(s-p) \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (11)$$

From (7) and (8),

$$D=\frac{\cos^2\delta-\cos^2\Delta}{\sin^2\Delta}, \qquad D'=\frac{\sin\delta\cos\delta}{\sigma\sin^2\Delta}\frac{d\delta}{dt} \quad . \quad . \quad . \quad . \quad (12)$$

Then, if we write for the ratio of the moon's parallax to her mean parallax P, we have

$$P-1=e\cos(s-p),$$

and

$$\Pi=\frac{1}{e}(P-1), \qquad \Pi'=-\frac{1}{e(\sigma-\varpi)}\frac{dP}{dt} \quad . \quad . \quad . \quad . \quad (13)$$

Hence D, D', Π, Π' are functions of declinations and parallaxes. The similar symbols with subscript accents are to apply to the sun.

Now (6) may be written by aid of (9) and (11),

$$2[t+h-s-(\nu_{\circ}-\xi)]=2\psi+4e\Pi'-D'\tan^2\Delta \quad . \quad . \quad . \quad (14)$$

The left-hand side of (14) is the argument of M_2 (see Sched. B. i. 1883), and from (9) the factor of M_2 is $\cos^2\Delta/\cos^2\Delta_{\prime}$. Hence, subtracting the retardation 2μ from (14) we have

$$(M_2)=\frac{\cos^2\Delta}{\cos^2\Delta_{\prime}}M\cos[(2\psi+4e\Pi'-D'\tan^2\Delta)-2\mu],$$

expanding approximately,

$$\begin{aligned} (M_2)=&\frac{\cos^2\Delta}{\cos^2\Delta_{\prime}}M\cos 2(\psi-\mu) \\ &-\frac{\cos^2\Delta}{\cos^2\Delta_{\prime}}\Pi' 4Me\sin 2(\psi-\mu) \\ &+\frac{\sin^2\Delta}{\cos^2\Delta_{\prime}}D'M\sin 2(\psi-\mu) \quad . \quad . \quad . \quad . \quad . \quad . (15) \end{aligned}$$

We shall see later that the two latter terms of (15) are nearly annulled by terms arising from other tides, and as in the case of the sun the rates of change of parallax and declination are small, we may write by symmetry,

$$(S_2)=S\cos 2(\psi_{\prime}-\zeta) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (16)$$

In all the smaller tides we may write

$$t+h-s-(\nu_{\circ}-\xi)=\psi.$$

A general formula of transformation will be required below. Thus, if $\cos 2x=X$, $\sin 2x=X'$,

$$\cos 2(\psi\mp x-\alpha)=(X\mp\tan 2(\alpha-\mu)X')\cos 2(\psi-\alpha)$$
$$\pm\frac{X'}{\cos 2(\alpha-\mu)}\sin 2(\psi-\mu) \quad . \quad (17)$$

The lunar K_2 *tide.*

From Sched. B. i., 1883, we have

$$\text{Lunar } K_2=\frac{\sin^2 I}{\sin^2\omega(1-\frac{3}{2}\sin^2 i)}K''\cos 2[t+h-\nu_{\circ}-\kappa]$$
$$=\frac{\sin^2\Delta}{\sin^2\Delta_{\prime}}K''\cos 2[\psi+(s-\xi)-\kappa].$$

Applying (17) with $X=D$, $X'=D'$, $\alpha=\kappa$, and taking the lower sign,

$$\text{Lunar } K_2=\frac{\sin^2\Delta}{\sin^2\Delta_{\prime}}K''\Big[(D+\tan 2(\kappa-\mu)D')\cos 2(\psi-\kappa)$$
$$-\frac{D'}{\cos 2(\kappa-\mu)}\sin 2(\psi-\mu)\Big]. \quad . \quad . \quad (18)$$

In the case of the sun we neglect the terms in D', for the same reasons as were assigned for the similar neglect in (16), and have

$$\text{Solar } K_2=K_{\prime}''D_{\prime}\cos 2(\psi_{\prime}-\kappa) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (19)$$

The tide N.

From Schedule B. i., Report 1883,

$$(\text{N})=\frac{\cos^4\frac{1}{2}I}{\cos^4\frac{1}{2}\omega\cos^4\frac{1}{2}i}N\cos[2(t+h-s-\nu_{\circ}+\xi)-(s-p)-2\nu].$$

Then $$(\text{N})=\frac{\cos^2\Delta}{\cos^2\Delta_{\prime}}N\cos 2[\psi-\nu-\tfrac{1}{2}(s-p)].$$

Then applying (17) with $X=\Pi$, $X'=\Pi'$, $\alpha=\nu$, and taking the upper sign, but writing $\mu-\nu$ instead of $\nu-\mu$, because this tide being slower than M_2 suffers less retardation,

$$(\text{N})=\frac{\cos^2\Delta}{\cos^2\Delta_{\prime}}N\Big[(\Pi+\tan 2(\mu-\nu)\Pi')\cos 2(\psi-\nu)$$
$$+\frac{\Pi'}{\cos 2(\mu-\nu)}\sin 2(\psi-\mu)\Big] \quad (20)$$

The tide L.

We shall here omit the small tide of speed $2\gamma-\sigma+\varpi$, by which the true elliptic tide is perturbed. Thus the R in the column of arguments in Sched. B. i., 1883, is neglected, and we have

$$(\text{L})=-\frac{\cos^4\frac{1}{2}I}{\cos^4\frac{1}{2}\omega\cos^4\frac{1}{2}i}L\cos[2(t+h-s-\nu+\xi)+(s-p)-2\lambda]$$
$$=-\frac{\cos^2\Delta}{\cos\Delta_{\prime}}L\cos 2[\psi-\lambda+\tfrac{1}{2}(s-p)].$$

Applying (17) with $X=\Pi$, $X'=\Pi'$, $a=\lambda$, and taking the lower sign, and changing the sign of the whole, because of the initial negative sign,

$$(\mathrm{L})=\frac{\cos^2\Delta}{\cos^2\Delta_{\prime}}L\Big[(-\Pi-\tan 2(\lambda-\mu)\Pi')\cos 2(\psi-\lambda)$$
$$+\frac{\Pi'}{\cos 2(\lambda-\mu)}\sin 2(\psi-\mu)\Big]. \quad (21)$$

The sum of N *and* L.

In order to fuse these terms an approximation will be adopted. The L tide is just as much faster than M_2 as N is slower, but the N tide should be nearly 7 times as great as the L tide; hence the $\tan 2(\lambda-\mu)$ in (21) will be put equal to $\tan 2(\mu-\nu)$. We then have

$$(\mathrm{N})+(\mathrm{L})=\frac{\cos^2\Delta}{\cos^2\Delta_{\prime}}\Big[(\Pi+\tan 2(\mu-\nu)\Pi')(N\cos 2(\psi-\nu)-L\cos 2(\psi-\lambda))$$
$$+\Pi'(N\sec 2(\mu-\nu)+L\sec 2(\lambda-\mu))\sin 2(\psi-\mu)\Big].$$

But

$$N\cos 2(\psi-\nu)-L\cos 2(\psi-\lambda)=\cos 2\psi(N\cos 2\nu-L\cos 2\lambda)$$
$$+\sin 2\psi(N\sin 2\nu-L\sin 2\lambda).$$

Then writing

$$\tan 2\epsilon=\frac{N\sin 2\nu-L\sin 2\lambda}{N\cos 2\nu-L\cos 2\lambda} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (22)$$

so that ϵ is nearly equal to ν, we have

$$(\mathrm{N})+(\mathrm{L})=\frac{\cos^2\Delta}{\cos^2\Delta_{\prime}}\,\frac{N\cos 2\nu-L\cos 2\lambda}{\cos 2\epsilon}\Big[(\Pi+\tan 2(\mu-\nu)\Pi')\cos 2(\psi-\epsilon)\Big]$$
$$+\frac{\cos^2\Delta}{\cos^2\Delta_{\prime}}\Big[(N\sec 2(\mu-\nu)+L\sec 2(\lambda-\mu))\sin 2(\psi-\mu)\Big] \quad . \quad (23)$$

In the symmetrical term for the sun, with approximation as in (16), we get

$$(\mathrm{T})+(\mathrm{R})=(T-R)\,\Pi_{\prime}\cos 2(\psi_{\prime}-\zeta) \quad . \quad . \quad . \quad . \quad . \quad . \quad (24)$$

This terminates the semidiurnal tides which we are considering; but before proceeding to collect the results some further transformations must be exhibited.

Let us consider the function $D+xD'$, where x is small. From (12) we see that

$$D+xD'=\frac{\cos^2\delta-\cos^2\Delta}{\sin^2\Delta}+\tfrac{1}{2}x\frac{2\sin\delta\cos\delta}{\sigma\sin^2\Delta}\,\frac{d\delta}{dt}.$$

Hence, if δ' be the moon's declination at a time earlier than the time of observation by $x/2\sigma$, then

$$D+xD'=\frac{\cos^2\delta'-\cos^2\Delta}{\sin^2\Delta}.$$

Hence, in (17),

$$D+\tan 2(\kappa-\mu)D'=\frac{\cos^2\delta'-\cos^2\Delta}{\sin^2\Delta} \quad . \quad . \quad . \quad . \quad . \quad (25)$$

when δ' is the moon's declination at time $\frac{1}{15}t-57^\circ{\cdot}3\tan 2(\kappa-\mu)/2\sigma$. The period $57^\circ{\cdot}3\tan 2(\kappa-\mu)/2\sigma$ may be called 'the age of the declinational inequality.'

Again,

$$\Pi+x\Pi'=\frac{1}{e}\left\{P-1-\frac{x}{\sigma-\varpi}\frac{dP}{dt}\right\}.$$

Hence, if $(P'-1)/e$ denotes the value of $(P-1)/e$ at a time $x/(\sigma-\varpi)$ earlier than that of observation, then

$$\Pi+x\Pi'=\frac{1}{e}(P'-1).$$

Hence, in (23),

$$\Pi+\tan 2(\mu-\nu)\Pi'=\frac{1}{e}(P'-1) \quad . \quad . \quad . \quad . \quad . \quad (26)$$

where P' is the ratio of the moon's parallax to her mean parallax at a time $\frac{1}{15}t-57^\circ\cdot3\tan 2(\mu-\nu)/(\sigma-\varpi)$. The period $57^\circ\cdot3\tan 2(\mu-\nu)/(\sigma-\varpi)$ may be called 'the age of the parallactic inequality.'

In collecting results we shall write the sum

$$\mathrm{M}_2+\mathrm{S}_2+\mathrm{K}_2+\mathrm{N}+\mathrm{L}+\mathrm{R}+\mathrm{T}=h_2.$$

For reasons explained below we omit terms depending on the rate of change of solar parallax and declination.

Then, from (15), (16), (18), (19), (23), (24), (25), (26), we have

$$\begin{aligned}
h_2=&\frac{\cos^2\Delta}{\cos^2\Delta_{,}}M\cos 2(\psi-\mu)+S\cos 2(\psi_{,}-\zeta)\\
&+\frac{\cos^2\delta'-\cos^2\Delta}{\sin^2\Delta_{,}}K''\cos 2(\psi-\kappa)+\frac{\cos^2\delta_{,}-\cos^2\Delta_{,}}{\sin^2\Delta_{,}}K_{,}''\cos 2(\psi_{,}-\kappa)\\
&-\frac{\sin\delta\cos\delta}{\sigma\sin^2\Delta_{,}}\frac{d\delta}{dt}\left(\frac{K''}{\cos 2(\kappa-\mu)}-M\tan^2\Delta_{,}\right)\sin 2(\psi-\mu)\\
&+\frac{\cos^2\Delta}{\cos^2\Delta_{,}}(P'-1)\frac{N\cos 2\nu-L\cos 2\lambda}{e\cos 2\epsilon}\cos 2(\psi-\epsilon)\\
&+(P_{,}-1)\frac{(T-R)}{e_{,}}\cos 2(\psi_{,}-\zeta)\\
&+\frac{\cos^2\Delta}{\cos^2\Delta_{,}}\frac{1}{\sigma-\varpi}\frac{dP}{dt}\left(4M-\frac{N\sec 2(\mu-\nu)+L\sec 2(\lambda-\mu)}{e}\right)\sin 2(\psi-\mu)
\end{aligned}\qquad (27)$$

It may easily be shown, from Schedule B. i., 1883, that in the equilibrium theory $K''-M\tan^2\Delta_{,}=0$, and $4M-(N+L)/e=0$; hence the terms depending on rates of change of declination and parallax are small. This also shows that we were justified in neglecting the corresponding terms in the case of the sun. Also, since the faster tides are more augmented by kinetic action than the slow ones, the two functions, written above, which vanish in the equilibrium theory are normally actually positive. The formula (27) gives the complete expression for the semidiurnal tide in terms of hour-angles, declinations, and parallaxes, with the constants of the harmonic analysis.

We shall now show that with rougher approximation (27) is reducible to a much simpler form.

The retardation of each tide should be approximately a constant, plus

a term varying with the speed. Hence all the retardations may be expressed in terms of ζ and μ, and

$$\kappa=\mu+\frac{\zeta-\mu}{\sigma-\eta}\sigma,$$

$$\nu=\mu-\frac{\zeta-\mu}{\sigma-\eta}\tfrac{1}{2}(\sigma-\varpi),$$

$$\lambda=\mu+\frac{\zeta-\mu}{\sigma-\eta}\tfrac{1}{2}(\sigma-\varpi).$$

It is clear that κ differs very little from ζ, and that

$$\frac{\kappa-\mu}{\sigma}=\frac{2(\mu-\nu)}{\sigma-\varpi}=\frac{\zeta-\mu}{\sigma-\eta}.$$

The time $(\zeta-\mu)/(\sigma-\eta)$ is called 'the age of the tide,' for reasons explained below, and $\kappa-\mu$, $\mu-\nu$, not being large angles, do not differ much from these tangents. Hence the ages of the declinational and parallactic inequalities are both approximately equal to the age of the tide.

Let æ, then, denote $(\zeta-\mu)/(\sigma-\eta)$, the age of the tide.

Now, as an approximation, we may suppose that heights of the lunar K_2 tide, the N and L tides bear the same ratio to the M_2 tide as in the equilibrium theory; and that the solar K_2, the T and R tides bear the same ratio to the S_2 tide as in that theory. Then reverting to the notation with I, ω, i in place of $\triangle$, $\triangle_{,,}$ and writing

$$\left(\frac{\cos\frac{1}{2}I}{\cos\frac{1}{2}\omega\cos\frac{1}{2}i}\right)^4=\text{f},$$

we have

$$\frac{\sin^2\triangle}{\sin^2\triangle_{,}}K''=\frac{\frac{1}{2}\sin^2 I}{\cos^4\frac{1}{2}I}\,\text{f}M,\quad \frac{\cos^2\triangle}{\cos^2\triangle_{,}}N=\tfrac{7}{2}e\text{f}M,\quad \frac{\cos^2\triangle}{\cos^2\triangle_{,}}L=\tfrac{1}{2}e\text{f}M,$$

$$K_{,}''=\frac{\frac{1}{2}\sin^2\omega}{\cos^4\frac{1}{2}\omega}S,\ T=\tfrac{7}{2}e_{,}S,\ R=\tfrac{1}{2}e_{,}S.$$

Also, since (22) may be written

$$\tan(2\mu-2\varepsilon)=\frac{N\sin 2(\mu-\nu)+L\sin 2(\lambda-\mu)}{N\cos 2(\mu-\nu)-L\cos 2(\lambda-\mu)},$$

we have, treating $\mu-\nu$, $\lambda-\mu$, $\mu-\varepsilon$ as small, approximately,

$$\varepsilon=\mu-\tfrac{2}{3}\text{æ}(\sigma-\varpi)=\mu-\tfrac{2}{3}(\lambda-\nu).$$

Also

$$\frac{\cos^2\triangle}{\cos^2\triangle_{,}}\,\frac{N\cos 2\nu-L\cos 2\lambda}{\cos 2\varepsilon}=3e\text{f}M.$$

Then reverting to mean longitudes, and substituting the age of tide where required, we find, on neglecting the difference between κ and ζ,

For the lunar declinational term,

$$2\tan^2\tfrac{1}{2}I\,\text{f}M\cos 2[s-\text{æ}\sigma-\xi]\cos 2(\psi-\zeta);$$

For the solar declinational term,

$$2\tan^2\tfrac{1}{2}\omega\,S\cos 2h\cos 2(\psi_{,}-\zeta);$$

For the lunar parallactic term,

$$3e\text{f}M\cos[s-p-\text{æ}(\sigma-\varpi)]\cos 2[\psi-\mu+\tfrac{2}{3}\text{æ}(\sigma-\varpi)];$$

For the solar parallactic term,

$$3e_{\prime}S\cos(h-p_{\prime})\cos 2[\psi_{\prime}-\zeta].$$

Then omitting the terms depending on changes of declination and parallax, we have as an approximation,

$$h_2=\mathrm{f}M\Big[\cos 2(\psi-\mu)+2\tan^2\tfrac{1}{2}I\cos 2[s-x\sigma-\xi]\cos 2(\psi-\zeta)$$
$$+3e\cos[s-p-x(\sigma-\varpi)]\cos 2[\psi-\mu+\tfrac{2}{3}x(\sigma-\varpi)]\Big]$$
$$+S\Big[1+2\tan^2\tfrac{1}{2}\omega\cos 2h+3e_{\prime}\cos(h-p_{\prime})\Big]\cos 2(\psi_{\prime}-\zeta)\quad . \quad . \quad (28)$$

In the equilibrium theory we have the lunar semidiurnal tide depending on $r^{-3}\cos^2\delta\cos 2\psi$. Now it is obvious that $\cos^2\delta$ introduces a factor $1+2\tan^2\frac{1}{2}I\cos 2(s-\xi)$, and r^{-3} a factor $1+3e\cos(s-p)$. Thus, if we could have foreseen the exact disturbance introduced by friction and other causes in the various angles, the formula (28) might have been established at once; but it seems to have been necessary to have recourse to the complete development in order to find how the age of the tide will enter.

§ 4. *Reference to Time of Moon's Transit.*

It has been usual to refer the tide to the time of moon's transit, and we shall now proceed to the transformations necessary to do so.

$\cos^2\triangle/\cos^2\triangle_{\prime}$ goes through its oscillation about the value unity in 19 years; it is therefore convenient to write for, say, a whole year,

$$\left.\begin{aligned} M_{\circ}&=\frac{\cos^2\triangle}{\cos^2\triangle_{\prime}}M\\ \text{and similarly,}\quad N_{\circ}&=\frac{\cos^2\triangle}{\cos^2\triangle_{\prime}}N\\ L_{\circ}&=\frac{\cos^2\triangle}{\cos^2\triangle_{\prime}}L \end{aligned}\right\}\quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (29)$$

We also observe that K'' and $K_{\prime}''$, being the lunar and solar parts of the mean K_2 tide, and their ratio being ·464 (Report, 1883),

$$K''=\cdot 68303\,K_2,\quad K_{\prime}''=\cdot 31697\,K_2\quad . \quad . \quad . \quad . \quad (30)$$

It will also be seen that in all the terms arising from the sun, excepting that in $K_{\prime}''$, the argument of the cosine is $2(\psi_{\prime}-\zeta)$. It will be convenient, and sufficiently accurate for all practical purposes, to replace κ by ζ in this solar declinational term $K_{\prime}''$.

We shall now proceed to refer the tide to the moon's transit at the place of observation.

Let $a_{\circ}$, $h_{\circ}$ be ☽'s R.A and ☉'s mean longitude at ☽'s transit—say upper transit, for distinctness. Then the local time of transit is given by the vanishing of ψ, and since $\psi=t+h-a$, it follows that the time-angle of ☽'s transit (at 15° to the hour) is $a_{\circ}-h_{\circ}$.

Now let τ (mean solar hours) be the interval after transit to which the time-angle t refers; then, since

$$\frac{dh}{dt}=\eta,\ \frac{da}{dt}=\sigma+\left(\frac{da}{dt}-\sigma\right),\ \gamma-\eta=15°,\ \gamma-\sigma=14°{\cdot}49,$$

$$\begin{aligned}\psi&=t+h-a\\&=[(\gamma-\eta)\tau+a_\circ-h_\circ]+[h_\circ+\eta\tau]-\left[a_\circ+\sigma\tau+\left(\frac{da}{dt}-\sigma\right)\tau\right],\end{aligned}$$

$$\psi=(\gamma-\sigma)\tau-\left(\frac{da}{dt}-\sigma\right)\tau.$$

For the sake of brevity, put

$$T=(\gamma-\sigma)\tau,$$

so that T is τ converted to angle at the rate of 14°·49 per hour. Then we have

$$\psi=T-\left(\frac{da}{dt}-\sigma\right)\tau \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (31)$$

Similarly putting $a_{\prime}$ for ☉'s R.A. at ☽'s transit, we have

$$\begin{aligned}\psi_{\prime}&=t+h-a_{\prime}\\&=[(\gamma-\eta)\tau+a_\circ-h_\circ]+[h_\circ+\eta\tau]-\left[a_{\prime}+\sigma\tau-\left(\sigma-\frac{da_{\prime}}{dt}\right)\tau\right];\end{aligned}$$

so that

$$\psi_{\prime}=(\gamma-\sigma)\tau+a_\circ-a_{\prime}+\left(\sigma-\frac{da_{\prime}}{dt}\right)\tau.$$

Then let

$$A=a_\circ-a_{\prime}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (32)^*$$

So that A is the apparent time of ☽'s transit, reduced to angle at 15° per hour, and we have

$$\psi_{\prime}=T+A+\left(\sigma-\frac{da_{\prime}}{dt}\right)\tau \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (33)$$

It is only in the two principal tides that we need regard the changes of R.A. since ☽'s transit, and in all the smaller terms we may simply put

$$\psi=T,\quad \psi_{\prime}=T+A.$$

The first pair of terms of (28) now become

$$M_\circ \cos 2\left[T-\left(\frac{da}{dt}-\sigma\right)\tau-\mu\right]+S\cos 2\left[T+A+\left(\sigma-\frac{da_{\prime}}{dt}\right)\tau-\zeta\right],$$

and these are equal to

$$M_\circ\cos 2(T-\mu)+S\cos 2(T+A-\zeta)$$

$$+\frac{2\pi}{180}\left(\frac{da}{dt}-\sigma\right)\tau M_\circ\sin 2(T-\mu)-\frac{2\pi}{180}\left(\sigma-\frac{da_{\prime}}{dt}\right)\tau S\sin 2[T+A-\zeta] \quad (34)$$

We may now collect together all the results, and write them in the form of a schedule.

* It would be better to put

$$A=a_\circ-a_{\prime}+\frac{\sigma-\eta}{\gamma-\sigma}\mu.$$

If this be used the correction (40) for ☉'s change of R.A. becomes small.

Semidiurnal Tides.—Schedule IV.

Description of Term	Coefficient	Periodic Factor
Principal lunar	$M_\circ$	$\times \cos 2(\mathrm{T}-\mu)$
Principal solar	$+S$	$\times \cos 2(\mathrm{T}+A-\zeta)$
☽ Change of R.A.	$+\frac{2\pi}{180}\left(\frac{d\alpha}{dt}-\sigma\right)\tau M_\circ$	$\times \sin 2(\mathrm{T}-\mu)$
⊙ Change of R.A.	$-\frac{2\pi}{180}\left(\sigma-\frac{d\alpha_{\prime}}{dt}\right)\tau S$	$\times \sin 2(\mathrm{T}+A-\zeta)$
☽ Declination	$+\frac{\cos^2\delta'-\cos^2\Delta}{\sin^2\Delta_{\prime}}\cdot 683\, K_2$	$\times \cos 2(\mathrm{T}-\kappa)$
⊙ Declination	$+\frac{\cos^2\delta_{\prime}-\cos^2\Delta_{\prime}}{\sin^2\Delta_{\prime}}\cdot 317\ K_2$	$\times \cos 2(\mathrm{T}+A-\zeta)$
☽ Change of declination . . .	$-\frac{\sin\delta\cos\delta}{\sigma\sin^2\Delta_{\prime}}\frac{d\delta}{dt}\left(\frac{\cdot 683\, K_2}{\cos 2(\kappa-\mu)}-M\tan^2\Delta_{\prime}\right)$ . . .	$\times \sin 2(\mathrm{T}-\mu)$
☽ Parallax.	$+(P'-1)\frac{N_\circ\cos 2\nu-L_\circ\cos 2\lambda}{e\cos 2\varepsilon}$	$\times \cos 2(\mathrm{T}-\varepsilon)$
⊙ Parallax	$+(P_{\prime}-1)\frac{T-R}{e_{\prime}}$	$\times \cos 2(\mathrm{T}+A-\zeta)$
☽ Change of parallax	$+\frac{1}{\sigma-\varpi}\frac{dP}{dt}\left(4M_\circ-\frac{N_\circ\sec 2(\mu-\nu)+L_\circ\sec 2(\lambda-\mu)}{e}\right)$	$\times \sin 2(\mathrm{T}-\mu)$.

Definition of symbols :—

α, δ, $\alpha_{\prime}$, $\delta_{\prime}$ ☽'s and ⊙'s R.A. and declination at moon's transit; $A=\alpha-\alpha_{\prime}$, apparent time of ☽'s transit at the port.

δ' ☽'s decl. at the time (generally earlier than transit) $\tau-\frac{57^{\circ}\cdot 3}{2\sigma}\tan 2(\kappa-\mu)$.

P, $P_{\prime}$ the ratio of ☽'s and ⊙'s parallax to mean parallaxes.

P' the ratio for ☽ at the time (generally earlier than transit) $\tau-\frac{57^{\circ}\cdot 3}{\sigma-\varpi}\tan 2(\mu-\nu)$.

τ the time elapsed since ☽'s transit in m.s. hours; T the same time reduced to angle at 14°·49 per hour.

Δ such a declination that $\cos^2\Delta$ is the mean value of $\cos^2\delta$; Δ has a 19-yearly period.

$\Delta_{\prime}$ such a declination that $\cos^2\Delta_{\prime}$ is the mean value of $\cos^2\delta_{\prime}$.

e, $e_{\prime}$ eccentricities of lunar and solar orbits; σ the ☽'s mean motion; ϖ the mean motion of the ☽'s perigee.

$$\frac{M_{\circ}}{M}=\frac{N_{\circ}}{N}=\frac{L_{\circ}}{L}=\frac{\cos^2\Delta}{\cos^2\Delta_{\prime}}.$$

M, S, K_2, N, L, T, R the mean semi-ranges H of the tides of those denominations in the harmonic method. The retardations found by harmonic analysis are 2μ for M_2, 2ζ for S_2, 2κ for K_2, 2ν for N, 2λ for L, and 2ζ for T and R.

Lastly $\tan 2\epsilon=\frac{N\sin 2\nu-L\sin 2\lambda}{N\cos 2\nu-L\cos 2\lambda}$, 2ϵ to be taken in the same quadrant as 2ν.

§ 5. *Synthesis of the Several Terms.*

Consider the two principal terms in Schedule IV.

$$M_{\circ}\cos 2(\mathrm{T}-\mu)+S\cos 2(\mathrm{T}+A-\zeta).$$

They may be written in the form

$$H\cos 2(\mathrm{T}-\phi),$$

where

$$H\cos 2(\mu-\phi)=M_{\circ}+S\cos 2(A-\zeta+\mu),$$
$$H\sin 2(\mu-\phi)=S\sin 2(A-\zeta+\mu).$$

If we compute ϕ corresponding to the time of moon's transit from the formula

$$\tan 2(\mu-\phi)=\frac{S\sin 2(A-\zeta+\mu)}{M_{\circ}+S\cos 2(A-\zeta+\mu)},$$

then ϕ reduced to time at the rate of 14°·49 per hour is the interval after moon's transit to high water, to a first approximation. The angle $\phi\pm 90^{\circ}$, similarly reduced, gives the low waters before and after the high water, and $\phi\pm 180^{\circ}$ gives another high water. The high waters and low waters are to be referred to the nearest transit of the moon.

The height or depression is given to a first approximation by

$$H=\sqrt{(M_{\circ}^2+S^2+2M_{\circ}S\cos 2\,(\mu-\phi))}.$$

This variability in the time and height of high water, due to variability of ϕ, is called the fortnightly or semi-menstrual inequality in the height and interval. The period $(\zeta-\mu)/(\sigma-\eta)$ is called 'the age of the tide,' because this is the mean period after new and full moon before the occurrence of spring tide.

§ 6. *Corrections.*

The smaller terms in Schedule IV. may be regarded as inequalities in the principal terms. They are of several types. Consider a term $B\cos 2(\mathrm{T}-\beta)$.

Then

$$B\cos 2(\mathrm{T}-\beta)=B\cos 2(\beta-\phi)\cos 2(\mathrm{T}-\phi)+B\sin 2(\beta-\phi)\sin 2(\mathrm{T}-\phi).$$

Hence the addition of such a term to $H\cos 2(\mathrm{T}-\phi)$ gives us $(H+\delta H)\cos 2(\mathrm{T}-\phi-\delta\phi)$, where

$$\delta H=B\cos 2(\beta-\phi),\ 2H\delta\phi=B\sin 2(\beta-\phi).\quad .\ .\ .\ .\quad (35)$$

Next consider a term $C\sin 2(\mathrm{T}-\mu)$. Putting $\beta=\mu+\frac{1}{4}\pi$, we have

$$\delta H=-C\sin 2(\mu-\phi),\ 2H\delta\phi=C\cos 2(\mu-\phi)\quad .\ .\ .\quad (36)$$

Next consider a term $E\cos 2(\mathrm{T}+A-\zeta)$. Putting $\beta=\zeta-A$, we have

$$\delta H=E\cos 2(A-\zeta+\phi),\ 2H\delta\phi=-E\sin 2(A-\zeta+\phi)\quad .\ .\quad (37)$$

Lastly, consider a term $F\sin 2(\mathrm{T}+A-\zeta)$. Putting $\beta=\zeta-A+\frac{1}{4}\pi$, we have

$$\delta H=F\sin 2(A-\zeta+\phi),\ 2H\delta\phi=F\cos 2(A-\zeta+\phi)\quad .\ .\quad (38)$$

In writing down the corrections we substitute $14{\cdot}49\delta t$ for $\delta\phi$, and introduce a factor so that the times may be given in mean solar hours and the angular velocities in degrees per hour.

Change of Moon's R.A., Sched. IV.

This is of type (36), and gives

$$\left.\begin{aligned}\delta H&=-\frac{2\pi}{180}\left(\frac{d\alpha}{dt}-\sigma\right)\tau M_\circ\sin 2(\mu-\phi)\\ \delta t&=1^{\mathrm{h}}{\cdot}977\frac{2\pi}{180}\left(\frac{d\alpha}{dt}-\sigma\right)\tau\frac{M_\circ}{H}\cos 2(\mu-\phi)\end{aligned}\right\}\quad .\ .\ .\ .\ .\quad (39)$$

This correction to the height is very small.

Change of Sun's R.A., Sched. IV.*

This is of type (38), and gives

$$\left.\begin{aligned}\delta H&=-\frac{2\pi}{180}\left(\sigma-\frac{d\alpha_{\prime}}{dt}\right)\tau S\sin 2(A-\zeta+\phi)\\ \delta t&=-1^{\mathrm{h}}{\cdot}977\frac{2\pi}{180}\left(\sigma-\frac{d\alpha_{\prime}}{dt}\right)\tau\frac{S}{H}\cos 2(A-\zeta+\phi)\end{aligned}\right\}\quad .\ .\quad (40)$$

* With the value of A suggested in footnote to (32) $(\sigma-d\alpha_{\prime}/dt)\tau$ becomes $[(\phi-\mu)\sigma-(\phi d\alpha_{\prime}/dt-\mu\eta)]/(\gamma-\sigma)$ at high water. This is obviously very small.

Moon's Declination, Sched. IV.

This is of type (35), and gives

$$\left.\begin{aligned}\delta H&=\frac{\cos^2\delta'-\cos^2\Delta}{\sin^2\Delta_{,}}\cdot 683K_2\cos 2(\kappa-\phi)\\ \delta t&=1^{\text{h}}\cdot 977\frac{\cos^2\delta'-\cos^2\Delta}{\sin^2\Delta_{,}}\cdot 683\frac{K_2}{H}\sin 2(\kappa-\phi)\end{aligned}\right\}\quad . \quad . \quad (41)$$

Sun's Declination, Sched. IV.

This is of type (37), and gives

$$\left.\begin{aligned}\delta H&=\frac{\cos^2\delta_{,}-\cos^2\Delta_{,}}{\sin^2\Delta_{,}}\cdot 317\,K_2\cos 2(A-\zeta+\phi)\\ \delta t&=-1^{\text{h}}\cdot 977\frac{\cos^2\delta_{,}-\cos^2\Delta_{,}}{\sin^2\Delta_{,}}\cdot 317\,\frac{K_2}{H}\sin 2(A-\zeta+\phi)\end{aligned}\right\}\quad . \quad . \quad (42)$$

Change of Moon's Declination, Sched. IV.

This is of type (36), and gives

$$\left.\begin{aligned}\delta H&=\frac{\sin\delta\cos\delta}{\sigma\sin^2\Delta_{,}}\;\frac{d\delta}{dt}\left(\frac{\cdot 683\,K_2}{\cos 2(\kappa-\mu)}-M\tan^2\Delta_{,}\right)\sin 2(\mu-\phi)\\ \delta t&=-1^{\text{h}}\cdot 977\frac{\sin\delta\cos\delta}{\sigma H\sin^2\Delta_{,}}\;\frac{d\delta}{dt}\left(\frac{\cdot 683\,K_2}{\cos 2(\kappa-\mu)}-M\tan^2\Delta_{,}\right)\cos 2(\mu-\phi)\end{aligned}\right\}(43$$

Moon's Parallax, Sched. IV.

This is of type (35), and gives

$$\left.\begin{aligned}\delta H&=(P'-1)\frac{N_{\circ}\cos 2\nu-L_{\circ}\cos 2\lambda}{e\cos 2\epsilon}\cos 2(\epsilon-\phi)\\ \delta t&=1^{\text{h}}\cdot 977(P'-1)\frac{N_{\circ}\cos 2\nu-L_{\circ}\cos 2\lambda}{He\cos 2\epsilon}\sin 2(\epsilon-\phi)\end{aligned}\right\}\quad . \quad . \quad (44)$$

Sun's Parallax, Sched. IV.

This is of type (37), and gives

$$\left.\begin{aligned}\delta H&=(P_{,}-1)\frac{T-R}{e_{,}}\cos 2(A-\zeta+\phi)\\ \delta t&=-1^{\text{h}}\cdot 977(P_{,}-1)\frac{T-R}{e_{,}H}\sin 2(A-\zeta+\phi)\end{aligned}\right\}\quad . \quad . \quad . \quad (45)$$

Change of Moon's Parallax, Sched. IV.

This is of type (36), and gives

$$\left.\begin{aligned}\delta H&=\frac{-1}{\sigma-\varpi}\;\frac{dP}{dt}\left(4M_{\circ}-\frac{N_{\circ}\sec 2(\mu-\nu)+L_{\circ}\sec 2(\lambda-\mu)}{e}\right)\sin 2(\mu-\phi)\\ \delta t&=\frac{1^{\text{h}}\cdot 977}{(\sigma-\varpi)H}\;\frac{dP}{dt}\left(4M_{\circ}-\frac{N_{\circ}\sec 2(\mu-\nu)+L_{\circ}\sec 2(\lambda-\mu)}{e}\right)\cos 2(\mu-\phi)\end{aligned}\right\}(46)$$

The lunar corrections involving sines are small compared with those involving cosines.

To evaluate these corrections we must compute τ from ϕ reduced to time at $14^{\circ}\cdot 49$ per hour.

In the right ascensional terms, $d\alpha/dt$ and σ are to be expressed in degrees per hour. $d\alpha/dt$ is the hourly change of ☽'s R.A. at time of ☽'s transit, and $d\alpha_{,}/dt$ is the hourly change of ☉'s R.A. at time of ☽'s transit.

Similarly, $d\delta/dt$ is to be expressed in degrees, if σ be in degrees.

δ', P' can be found for the antecedent moments, $57^\circ{\cdot}3 \tan 2(\kappa-\mu)/2\sigma$, and $57^\circ{\cdot}3 \tan 2(\mu-\nu)/(\sigma-\varpi)$, before the time τ.

§ 7. *The Diurnal Tides.*

I shall not consider these tides so completely as the semidiurnal ones, although the method indicated would serve for an accurate discussion, if it be desired to make one.

The important diurnal tides are K_1, O, P.

From Schedule B ii., 1883, we have

$$(\mathrm{O})=\frac{\sin I \cos^2 \frac{1}{2}I}{\sin \omega \cos^2 \frac{1}{2}\omega \cos^4 \frac{1}{2}i} M' \cos \left[t+h-\nu_\circ-2(s-\xi)+\tfrac{1}{2}\pi-\mu'\right].$$

By (9) the coefficient is $\sin 2\Delta/\sin 2\Delta_{\prime\prime}$, and we shall put, as in the case of the semidiurnal tides,

$$M_\circ'=\frac{\sin 2\Delta}{\sin 2\Delta_\prime} M'.$$

Then, since $t+h=\psi+\alpha$,

$$\begin{aligned}(\mathrm{O})&=M_\circ' \cos \left[\psi+(\alpha+\nu_\circ)-2(s-\xi)+\tfrac{1}{2}\pi-\mu'\right]\\ &=M_\circ' \cos \Omega, \text{ for brevity} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (47)\end{aligned}$$

Again, from Schedule C, 1883,

$$(\mathrm{P})=S' \cos \left[t-h+\tfrac{1}{2}\pi-\zeta'\right];$$

Then let $\chi=2(s-h)+\nu_\circ-2\xi-\zeta'+\mu'$, and we have

$$(\mathrm{P})=S' \cos (\Omega+\chi) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (48)$$

Whence

$$(\mathrm{O})+(\mathrm{P})=[M_\circ'+S' \cos \chi] \cos \Omega-S' \sin \chi \sin \Omega.$$

If we put,

$$\begin{aligned}H' \cos (\mu'-\phi')&=M_\circ'+S' \cos \chi\\ H' \sin (\mu'-\phi')&=S' \sin \chi.\end{aligned}$$

$$\begin{aligned}(\mathrm{O})+(\mathrm{P})&=H' \cos (\Omega+\mu'-\phi')\\ &=H' \cos \left[\psi+(\alpha-\nu_\circ)-2(s-\xi)+\tfrac{1}{2}\pi-\phi'\right] \quad . \quad (49)\end{aligned}$$

Where

$$\left.\begin{aligned}H'&=\sqrt{\{M_\circ'^2+S'^2+2M_\circ'S' \cos \chi\}}\\ \text{and} \qquad \tan (\mu'-\phi')&=\frac{S' \sin \chi}{M_\circ'+S' \cos \chi}\end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad . \quad (50)$$

The rate of increase of the angle χ is twice the difference of the mean motions of the moon and sun, but it would be more correct to substitute for s and h the true longitudes of the bodies. It follows from (50) that ϕ' has a fortnightly inequality like that of ϕ.

ψ is very nearly equal to T, and where the diurnal tide is not very large we may with sufficient approximation put

$$(\alpha-\nu_\circ)-2(s-\xi)=-(s-\xi).$$

So that with fair approximation

$$(\mathrm{O})+(\mathrm{P})=H' \cos \left[\mathrm{T}-(s-\xi)+\tfrac{1}{2}\pi-\phi'\right] \quad . \quad . \quad . \quad . \quad (51)$$

The synthesis of the two parts of the K_1 tide has been performed in the harmonic method (Report, 1883), and we have

$$(K_1)=f_1 K_1 \cos(t+h-\nu'-\tfrac{1}{2}\pi-\kappa_1).$$

Then, writing $f_1 K_1 = K_o$, we have

$$(K_1)=K_o \cos(T+\alpha-\nu'-\tfrac{1}{2}\pi-\kappa_1) \quad . \quad . \quad . \quad . \quad (52)$$

We have next to consider what corrections to the time and height of high and low water are necessary on account of these diurnal tides.

If we have a function

$$h=B+H\cos 2(T-\phi)+H_1\cos(nT-\beta),$$

where n is nearly equal to unity, and H_1 is small compared with H; its maxima and minima are determined by

$$\sin 2(T-\phi)=-\frac{H_1 n}{2H}\sin(nT-\beta).$$

If $T=T_o$ be the approximate time of maximum, and $T_o+\delta T_o$ the true time, then, since the mean lunar day is 24·84 hours, and the quotient when this is divided by 8π is 0^h·988, we have in mean solar hours,

$$\left.\begin{array}{l}\delta T_o=-0{\cdot}988\dfrac{H_1 n}{H}\sin(nT_o-\beta) \\ \text{And the correction to the maximum is} \\ \delta H=H_1\cos(nT_o-\beta)\end{array}\right\} \quad . \quad . \quad . \quad (53)$$

Again if $T=T_1$ be the approximate time of minimum, and $T_1+\delta T_1$ the true time, then

$$\left.\begin{array}{l}\delta T_1=0{\cdot}988\dfrac{H_1 n}{H}\sin(nT_1-\beta) \\ \text{And the correction to the minimum is} \\ \delta H=H_1\cos(nT_1-\beta)\end{array}\right\} \quad . \quad . \quad . \quad (54)$$

In the case of the correction due to $(O)+(P)$, n is approximately $1-\dfrac{\sigma}{\gamma-\sigma}$, and for the correction due to K_1, n is approximately $1+\dfrac{\sigma}{\gamma-\sigma}$.

§ 8. *Direct Synthesis of the Harmonic Expression for the Tide.*

The scope of the preceding investigation is the establishment of the nature of the connection between the older treatment of tidal observation and the harmonic method. It appears, however, that if the results of harmonic analysis are to be applied to the numerical computation of a tide-table, then a direct synthesis of the harmonic form may be preferable to a transformation to moon's transit, declinations, and parallaxes.

Semidiurnal Tides.

We shall now suppose that M_o is the height of the M_2 tide, augmented or diminished by the factor for the particular year of observation, according to the longitude of the moon's node, and similarly K_o generically for the augmented or diminished height of any of the smaller tides. As

before, let 2μ, 2ζ be the lags of M_2, S_2; and 2κ, generically, the lag of the K tide.

Let $$\theta=t+h-s-\nu_o+\xi.$$

Then θ might be defined as the mean moon's hour-angle, the mean moon coinciding with the true, not at Aries, but at the intersection.

Let the argument of the K tide be written generically $2[\theta+u-\kappa]$.

Then

$$h_2=M_o \cos 2(\theta-\mu)+S \cos 2[\theta+s-h+\nu_o-\xi-\zeta]+K_o \cos 2[\theta+u-\kappa] \quad . \quad . \quad . \quad (55)$$

If we write

$$\zeta_o=\zeta-\nu_o+\xi,$$

and

$$H \cos 2(\mu-\phi)=M_o+S \cos 2[s-h-\zeta_o+\mu]$$
$$H \sin 2(\mu-\phi)=S \sin 2[s-h-\zeta_o+\mu],$$

the first two terms of (55) are united into

$$H \cos 2(\theta-\phi) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (56)$$

with fortnightly inequality of time and height defined by

$$\left.\begin{aligned} \tan 2(\mu-\phi)&=\frac{S \sin 2(s-h-\zeta_o+\mu)}{M_o+S \cos 2(s-h-\zeta_o+\mu)} \\ H&=\surd[M_o^2+S^2+2MS \cos 2(s-h-\zeta_o+\mu)] \end{aligned}\right\} \quad . \quad . \quad . \quad (57)$$

The amount of the fortnightly inequality depends to a small extent on the longitude of the moon's node, since ζ_o and M_o are both functions of that longitude.

For the K tide we have

$$K_o \cos 2(\theta+u-\kappa)=K_o \cos 2(u-\kappa+\phi) \cos 2(\theta-\phi)$$
$$-K_o \sin 2(u-\kappa+\phi) \sin 2(\theta-\phi).$$

Hence

$$\left.\begin{aligned} \delta H&=\quad K_o \cos 2(u-\kappa+\phi) \\ \delta\phi&=-\frac{K_o}{2H} \sin 2(u-\kappa+\phi) \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (58)$$

It is easy to find from the Nautical Almanac (see Moon's Libration) the exact time of mean moon's transit on any day, and then the successive additions of $12^h\cdot420601$ or $12^h\ 25^m\ 14^s\cdot16$ give the successive upper and lower transits. The successive values of $2(s-h)$ may be easily found by successively adding $12^\circ\cdot618036$ to the initial value at the time of the first transit of the mean moon, and ϕ may be obtained from the table of the fortnightly inequality for each value of $2(s-h)$.

The function u is slowly varying, e.g., for the K_2 tide $2u=2(s-\xi)+2(\nu_o-\nu'')$, and the increment of argument for each $12^h\cdot420601$ may be easily computed once for all, and added to the initial value.

In the case of the diurnal tides it will probably be most convenient to apply corrections for each independently, following the same lines as those sketched out in § 5.

The corrections for the over tides M_4, S_4, &c., and for the terdiurnal

and quaterdiurnal compound tides, would also require special treatment, which may easily be devised.

At ports, where the diurnal tide is nearly as large or larger than the semidiurnal, special methods will be necessary.

Although the treatment in terms of mean longitudes makes the corrections larger than in the other method, yet it appears that the computation of a tide-table may thus be made easier, with less reference to ephemerides, and with amply sufficient accuracy.

Report of the Committee, consisting of Mr. ROBERT H. SCOTT (*Secretary*), Mr. J. NORMAN LOCKYER, Professor G. G. STOKES, Professor BALFOUR STEWART, *and* Mr. G. J. SYMONS, *appointed for the purpose of co-operating with the Meteorological Society of the Mauritius in their proposed publication of Daily Synoptic Charts of the Indian Ocean from the year* 1861. *Drawn up by* Mr. R. H. SCOTT.

THE Committee have the honour to forward, for the inspection of the members of the Association, a copy of the Charts for the month of March 1861, with some specimens for January of the same year, and the complete number for February which appeared some years ago. These documents have recently arrived from the Mauritius.

As the work has now made decided progress, the Committee have applied for and obtained the grant of 50*l.* placed at their disposal by the General Committee.

As soon as the requisite documents are received from Dr. Meldrum, the Committee will submit a formal account of their expenditure with the necessary vouchers.

Report of the Committee, consisting of Mr. JAMES N. SHOOLBRED (*Secretary*) *and* Sir WILLIAM THOMSON, *appointed for the reduction and tabulation of Tidal Observations in the English Channel, made with the Dover Tide-gauge; and for connecting them with Observations made on the French coast.*

YOUR Committee herewith beg to submit the High Water and the Low Water Observations for the years 1880, 1881, 1882, and 1883, obtained from the records of the self-registering tide-gauges at the ports of Dover and of Ostend respectively.

The observations, in order to facilitate comparisons, are reduced to Greenwich time and to the common datum-plane of 20 feet below the Ordnance datum of Great Britain.

As the reduction and tabulation of the present series of tidal observations has proved a longer operation than was anticipated, there has been hardly sufficient time to consider the best form in which those observations should be placed for comparison, nor for the more suitable deductions which may be drawn from such comparison.

Your Committee, therefore, request to be reappointed.

Report of the Committee, consisting of Professor G. FORBES (*Secretary*), Captain ABNEY, Dr. J. HOPKINSON, Professor W. G. ADAMS, Professor G. C. FOSTER, Lord RAYLEIGH, Mr. PREECE, Professor SCHUSTER, Professor DEWAR, Mr. A. VERNON HARCOURT, *and* Professor AYRTON, *appointed for the purpose of reporting on Standards of White Light. Drawn up by* Professor G. FORBES.

THE experimental work of the Committee during the past year has not been extensive, as they had no funds at their disposal for experimental research, and they have been chiefly occupied with reviewing what has been done in the past and laying plans for future operations.

Lord Rayleigh has constructed an instrument which he calls a monochromatic telescope, by means of which the illuminated screens of a photometer may be examined, allowing light only of one definite colour to pass. It was hoped by Lord Rayleigh that experiment might show that, with some suitably chosen colour, this instrument, used with any ordinary photometer, would, in comparing lights of different intensities and temperatures, give to each a candle-power which would be sufficiently accurate to represent for commercial purposes the intensity of the light. The Secretary has made some experiments at the Society of Arts, where he was kindly permitted to use the secondary batteries and glow lamps; but the results so far are not definite enough to justify their publication.

Mr. Vernon Harcourt has been engaged on an investigation on the barometrical correction to his pentane standard, and on another concerning the possibility of using lamp-shades as a protection from air currents. His researches are communicated independently to the meeting.

Captain Abney and General Festing have continued their observations on the intensity of radiations of different wave-lengths from incandescent carbon and platinum filaments at different temperatures, which will go far to assist the Committee in their work.

Other isolated experiments have been made by members of the Committee, which will be published in due course.

Most of the members have examined the experiments of the Trinity Board at the South Foreland.

Existing Standards.

A consideration of existing standards convinces the Committee that the standard candle, as defined by Act of Parliament, is not in any sense of the word a standard. The French 'bec Carcel' is also liable to variations; and with regard to the molten platinum standard of Violle, it seems that the difficulty of applying it is so great as to render its general adoption almost impossible.

With regard to the so-called standard candle, the spermaceti employed is not a definite chemical substance, and is mixed with other materials, and the constitution of the wick is not sufficiently well defined. Hence it is notorious that interested parties may prepare candles conforming to the definitions of the Act which shall favour either the producer or consumer to a serious extent. In view of these defects of the standard candle, it is a matter of great importance that a standard of light should be chosen which is more certain in its indications.

The Committee have looked into the merits of different proposed standards, and the majority feel satisfied that, for all the present com-

mercial requirements, the pentane standard of Mr. Vernon Harcourt—since it has no wick and consumes a material of definite chemical composition—when properly defined, is an accurate and convenient standard, and gives more accurately than the so-called standard candle an illumination equal to that which was intended when the Act was framed.

Yet the Committee, while desiring to impress the Board of Trade and the public with these views, do not feel inclined at present to recommend the adoption of any standard for universal adoption until, further information on radiation having been obtained from experiment, they may learn whether or not it may be possible to propose an absolute standard, founded, like electrical and other standards, on fundamental units of measurement—a standard which, for these reasons, would be acceptable to all civilised nations. They are, however, inclined to look upon the pentane lamp as an accurate means of obtaining an illumination to replace the so-called standard candle.

Proposed Experimental Researches.

Radiation is measured as a rate of doing work, and consequently radiation might be measured in watts. The illumination (or luminous effect of radiation) depends partly upon the eye, and is a certain function of the total radiation. This function depends upon the wave-length of the radiation, or on the different wave-lengths of which the radiation, if it be compound, is composed. This function of the radiation perceived by the eye is partly subjective, and varies with radiations of different wave-lengths and with different eyes. Thus the illumination cannot, like the radiation, be expressed directly in absolute measurement. But the connection between the illumination and the radiation can be determined from a large number of experiments with a large number of eyes, so as to get the value of the function for the normal human eye. This function, however, is constant only for one source of light, or, it may be, for sources of light of the same temperature. It appears, then, that, in the first instance at least, a standard should be defined as being made of a definite material at a special temperature.

The energy required to produce a certain radiation in the case of a thin filament of carbon or platinum-iridium heated by the passage of an electric current can be easily measured by the ordinary electric methods, and the radiation may be measured by a thermopile or a bolometer, which itself can be standardised by measuring the radiation from a definite surface at 100° C., compared with the same at 0° C. The electric method measures the absorption of energy; the thermopile measures the total radiation. These two are identical if no energy is wasted in convection within the glass bulb of the lamp, by reflection and absorption of the glass, and by conduction from the terminals of the filament. Captain Abney and General Festing have come to the conclusion that there is no sensible loss from these causes. The Committee propose to investigate this further. This constitutes a first research.

No research is necessary to prove that with a constant temperature of a given filament the luminosity is proportional to the radiation, because each of these depends only upon the amount of surface of the radiating filament. It will be necessary, however, to examine whether with different filaments it be possible to maintain them at such temperatures as shall make the illumination of each proportional to the radiation. This will be the case if spectrum curves, giving the intensity of radiation in

terms of the wave-length when made out for the different sources of light, are of the same form. Thus a second research must be undertaken to discover whether the infinite number of spectrum radiation curves, which can be obtained from a carbon filament by varying the current, are identical in form when the filament is changed, but the material remains so far as possible of constant composition.

It will be an object for a later research to determine whether, when the radiation spectrum curve of any source of light has been mapped, a similar curve can be found among the infinite number of curves which can be obtained from a single filament.

The next step proposed is to examine a large number of carbon or of platinum-iridium filaments, and to find whether the radiation spectrum curve of different specimens of the same material is identical when the resistance is changed in all to x times the resistance at 0° C. If this law be true, a measurement of the resistance of the filament would be a convenient statement of the nature of the radiation curve. If, then, a number of filaments were thus tested to give the same radiation spectrum curve, their luminosities would in all cases be proportional to their radiations, or (if there be no loss in convection, conduction, absorption, and reflection) proportional to the electrical energies consumed.

Thus it might be hoped to establish a standard of white light, and to define it somewhat in the following manner:—*A unit of light is obtained from a straight carbon filament, in the direction at right angles to the middle of the filament, when the resistance of the filament is one-half of its resistance at 0° C., and when it consumes 10^9 C.G.S. units of electrical energy per second.*

Since Mr. Swan has taught us how to make carbon filaments of constant section by passing the material of which they are composed through a die, it is conceivable that another absolute standard should be possible—viz., a carbon filament of circular section, with a surface, say, $\frac{1}{100}$ sq. centimètre, and consuming, say, 10^9 C.G.S. units of energy per second.

Whether such standards are possible or not depends upon the experiments of the Committee. The probability of success is sufficient to render these experiments desirable.

Proposed Later Experimental Researches.

Should these hopes be realised, and an absolute standard of white light thus obtained of a character which would commend it to the civilised world, it would then become an object of the Committee to find the ratio of luminosity when the radiation spectrum curve of the standard filament is varied by varying the current, and consequently the resistance of the filament.

Thus, by a large number of subjective experiments on human eyes, a multiplier would be found to express the illumination from the standard lamp, with each degree of resistance of the filament.

A research, previously hinted at, would then be undertaken—viz., to find whether the radiation spectrum curves of all sources of illumination agree with one or other of the curves of the standard filament. It is not improbable that this should be the case except for the high temperature of the electric arc.

Should this be found to be true, then photometry would be very accurate, and the process would be as follows:—*Adjust the standard filament until its radiation spectrum curve is similar to that of the light to be*

compared. (This would probably be best done by observing the wave-length of the maximum radiation, or by observing equal altitudes on either side of the maximum, the instruments used being a spectroscope and a line thermopile or a bolometer.) The total radiation of each is then measured at equal distances by the thermopile. The resistance of the filament is measured, and its intensity in terms of the unit of white light obtained therefrom by the previous research. The luminosity of the compared source of light is then obtained directly.

The Committee desire to be reappointed, and to enable them to carry out the researches indicated they ask for a grant of 30*l.*

Second Report of the Committee, consisting of Professor BALFOUR STEWART (*Secretary*), Mr. J. KNOX LAUGHTON, Mr. G. J. SYMONS, Mr. R. H. SCOTT, *and* Mr. JOHNSTONE STONEY, *appointed for the purpose of co-operating with* Mr. E. J. LOWE *in his project of establishing a Meteorological Observatory near Chepstow on a permanent and scientific basis.*

SINCE their reappointment in 1884 this Committee have met twice, and have placed themselves in correspondence with Mr. Lowe.

In this correspondence the Committee have expressed their opinion that the establishment of a permanently endowed meteorological observatory on a good site, such as that of Shire Newton, is a matter of undeniable scientific importance.

The attitude which the Committee have taken will be rendered apparent by the following letter written by their Secretary to Mr. Lowe:—

'The Committee request me to point out to you that the main feature of your proposal, which interests the British Association and the scientific public generally, is the prospect which it holds out of the establishment of a *permanent* institution by means of which meteorological constants could be determined, and any secular change which may take place therein in the course of a long period of years be ascertained. It will be for you and the local authorities to decide what amount of work of *local interest* should be contemplated, and on this will the scale of the observatory mainly depend. The Committee are therefore unable to say what amount of capital would be required. They would point out four conditions which they hold to be indispensable:—

'1. The area of ground appropriated should be sufficient to ensure freedom from the effect of subsequent building in the neighbourhood.

'2. A sufficient endowment fund of at least 150*l.* annually should be created.

'3. The control should be in the hands of a body which is in itself permanent as far as can be foreseen.

'4. The land for the site shall be handed over absolutely to the above-mentioned governing body.'

This communication from the Committee is now under the consideration of Mr. Lowe and his friends, but until the precise amount of the local meteorological requirements is ascertained and further progress is made in the scheme the Committee consider that they would not be justified in any more prominent action than that which they have already taken.

They would request their reappointment, and that the unexpended sum of 25*l.* be again placed at their disposal.

Report of the Committee, consisting of Professor BALFOUR STEWART (*Secretary*), Sir W. THOMSON, Sir J. H. LEFROY, Sir FREDERICK EVANS, Professor G. H. DARWIN, Professor G. CHRYSTAL, Professor S. J. PERRY, Mr. C. H. CARPMAEL, *and* Professor SCHUSTER, *appointed for the purpose of considering the best means of Comparing and Reducing Magnetic Observations. Drawn up by* Professor BALFOUR STEWART.

IN presenting their report to the British Association the Committee would begin by referring to the appendix, in which are embodied suggestions of great value which they have received from men of science at home and abroad. The Committee desire to express their thanks to the authors of these contributions.

While a final discussion of these communications cannot be attempted in this first report, it is nevertheless evident that magneticians are not agreed as to the best method of determining absolutely the solar-diurnal variations of the three magnetic elements—that is to say, the diurnal variation resulting after the elimination of all disturbed observations. The point in dispute is the method of distinguishing and separating the disturbed from the undisturbed observations. On the whole, the feeling is against the method of Sabine, on account of the arbitrary nature of his separating value.

An alternative method has been proposed by Dr. Wild, Director of the Central Russian Observatory (Appendix, No. VII.). This method seems to be in some degree analogous to that pursued at Greenwich (Appendix, No. IX.). Dr. Wild selects those curves which appear to the eye to be free from the short-period irregularities characteristic of disturbances, and considers the results obtained from their measurement to embody a trustworthy representation of the solar-diurnal variation for the time and place in question. He finds a remarkable uniformity and simplicity of type in the variation as given by the different selected curves.

While the Committee recognise in this a method which may ultimately meet with general acceptance, they think there are various points connected with it which require investigation.

In the first place, it would be desirable to prove, by means of an exhaustive discussion of some one element—as, for instance, the declination—to what extent curves selected by the eye do, as a matter of fact, present this uniformity and simplicity of type.

There are abundant materials available for this purpose at the Kew Observatory, and it is hoped that through the kindness of the Kew Committee this point may eventually be settled.

Again, it would be desirable to ascertain whether the apparently normal days at one station coincide with those at another; and, if so, whether there is a definite or nearly definite relation in type and range between the corresponding smooth curves of two widely separated stations of not very dissimilar latitude.

This point will form one of the subjects of a discussion undertaken by Sir J. Henry Lefroy, who proposes to compare the curves of Toronto and those of Greenwich together for the years 1849–53.

The Committee are of opinion that these are steps which might at once be taken, so as to push on this part of the subject.

The Committee would call attention to the completeness of the magnetical information which is given by the present method of publication adopted by the Astronomer Royal. He now gives, in addition to the mean values of the magnetic elements for each day and the mean diurnal curves for each month, the amplitude of the diurnal curve for each day, and particulars of all disturbances, small as well as large. (See Appendix, No. IX.)

Until a method is generally accepted for determining the normal solar-diurnal variation, it seems premature to raise any discussion on the best way of estimating disturbances, since these cannot well be measured except from the basis of such a normal.

The Committee would, however, allude to various investigations, chiefly connected with disturbance, which are being undertaken by some of its members. The thought seems generally to have occurred that disturbances may denote the method by which the earth *rights itself* with respect to the magnetic forces acting upon it (see Appendix, No. II., paragraphs 11 and 12), and this idea underlies the various researches about to be named.[1]

The first of these is that already mentioned as having been taken up by Sir J. H. Lefroy, with the concurrence of the Astronomer Royal—namely, a comparison of magnetic movements photographically recorded at Toronto and Greenwich in the years 1849–53. Stations so far asunder (3,100 miles), and on different continents, appear calculated to throw light on many questions which are not much advanced by comparison of stations in geographical proximity.

The following are *primâ facie* conclusions which may require modification when the work has been gone through, but which already seem to have a bearing on the physical explanation of the phenomena :—

a. A similar state of magnetic weather, so to speak, prevails generally at both stations, so that where numerous or extensive deviations from normal regularity occur at the one, there is generally something corresponding at the other.

b. The correspondence very seldom amounts to similarity of movement or identity of time.

c. The changes of declination at Toronto are more rapid than at Greenwich. This is especially observable about the time of the morning easterly extreme. Bold sweeping curves with a long time measure are much less common at Toronto than at Greenwich, and can seldom be identified.

d. On the other hand, shocks of small angular amount breaking a uniform line are often capable of identification, and are simultaneous, or nearly so, at both stations.

e. Although the declination was westerly at both stations, the movements of disturbance are very frequently, probably usually, in opposite directions at any given time—easterly at Greenwich, or decreasing the absolute declination, when they are westerly, or increasing it, at Toronto.

f. The same days would generally be selected to form normal curves at both stations.

[1] A similar idea seems to have occurred to Dr. Wild (see foot-note to his communication, Appendix, No. VII.).

g. Slight auroral displays in Canada generally produce a marked effect at Toronto, but none at Greenwich.

h. It is not easy to answer the question whether a state of disturbance succeeding one of calm begins or ends at the same time at both stations, neither beginning or ending being, in general, sufficiently definitely marked.

i. It appears impossible to assign a value based on angular movement alone which will be a valid test, whether such movement is due to disturbing causes or not.

j. Angular movements at Toronto appear to be larger than at Greenwich, the magnets being (in 1849–50) similar—namely, 2 feet in length.

The second research is by the Rev. S. J. Perry and Professor Stewart, who, with the sanction of the Kew Committee, are engaged in a comparison of the simultaneous disturbances of the declination at Stonyhurst and at Kew. Calling the first S, and the second K, they have obtained the following preliminary results, which may, however, ultimately require some modification :—

(1) S is always greater than K, or the ratio $\frac{S}{K}$ is always greater than unity.

(2) This ratio appears to depend in some way on the duration of the disturbance.

(3) But not, as far as can be seen at present, upon its magnitude.

A third research is by Professor Stewart and Mr. W. Lant Carpenter, who are making a preliminary trial of four years of Kew declination disturbances (separated by Sabine's method), in order to ascertain whether the aggregate daily disturbance depends upon the relative position of the sun and moon, and also whether it is affected by meteorological storms. The following provisional result has been obtained from the years 1870–73 in which the lunation is divided into 8 parts, (0) denoting new, and (4) full moon.

Mean Daily Aggregate of Disturbance of Declination at Kew.[1]

(Unit $\frac{1}{100}$th of an inch, measured on the curve.)

(0)	(1)	(2)	(3)	(4)	(5)	(6)	(7)
111	114	104	95	83	94	107	101

The Committee desire to draw the attention of magneticians to the urgent need of obtaining more accurate knowledge than we possess at present of the daily variation of the vertical force. No attempt to fix the cause of the daily variation can be made until the daily variation of each component of the magnetic force is known.

In conclusion, the Committee desire their reappointment, with the addition to their number of Captain Creak and of Mr. G. M. Whipple, Director of the Kew Observatory, and they would request that the sum of 50*l.* should be placed at their disposal, to be spent as they may think best on the researches mentioned in this report.

[1] The late Professor J. Clerk Maxwell was, it is believed, the first to suggest that the lunar-diurnal variation of the earth's magnetism may be caused by distortion, and Dr. Schuster has suggested that, if there is found to be a relation between magnetic disturbances and atmospheric storms, it may be of the same nature.

APPENDIX.

Suggestions for the Committee on Magnetical Reductions.

I. By Professor Balfour Stewart, F.R.S.

1. The following suggestions are founded on the methods proposed by several magneticians, including Sabine, Broun, Lefroy, Capello, and Buys Ballot. To Senhor Capello I am especially indebted for the trouble he has taken in explaining his views, with which these suggestions are almost identical.

2. The measurements derived from self-recording magnetographs may be used for two purposes, the first being to ascertain the *solar diurnal variation*, by which name we designate that variation which is exhibited by comparatively undisturbed observations. The second of these purposes is to ascertain *the laws which regulate disturbances.* Now disturbances may act in two ways. *First*, they may exhibit a diurnal variation different from that of the undisturbed observations, which we may call the *disturbance diurnal variation*; and, *secondly*, they may exalt or depress the day's value of the particular element in question.

As a matter of fact I believe they act in both these ways. It appears to me that it is of very great importance that these two effects of disturbance should be exhibited and studied together, and yet not improperly mixed up with one another.

3. Let me explain my meaning with reference to the method of Sabine, which I believe to be, in many respects, an excellent one. Sabine did a very great deal in finding out and exhibiting the diurnal variations of the disturbed and undisturbed observations, but he did not greatly study, along with these, the effect of disturbances in altering the daily mean values of an element, so that it was reserved for Broun to discover that there were changes in the daily values of the horizontal force which were practically simultaneous at the various stations of the globe. Let us first of all consider the hourly values of declination, as this element presents fewest difficulties.

Declination.

4. Here, I imagine, the first thing is to determine the *solar diurnal variation*, or that presented by the comparatively undisturbed observations, and for this purpose I fail to see a better plan than that proposed by Sabine. This method may be described as follows:

5. Suppose that we have hourly observations at a station, then, first of all, we should arrange these into monthly groups, each hour by itself. We should then reject, as disturbed observations, all those which differ by more than a certain amount from their respective normals of the same month and hour, the normals being the hourly means in each month after the exclusion of all the disturbed observations. For the purpose of ascertaining the true solar diurnal variation, it seems probable that a considerable choice might be allowed in selecting the separating value implied in the above process, one value serving, *for this purpose*, probably as well as another a little above or below it.

6. Perhaps under ordinary circumstances a value which will exclude as disturbed about one-twentieth of the whole body of observations will be found convenient.

7. Let us now imagine that we have determined by this process

the undisturbed normals for each hour, for each month. I agree with Sir J. H. Lefroy in thinking that the best plan of investigating disturbances is, in the first place, to obtain the various departures of individual observations from their respective normals for that month and hour. It would be desirable to embody these departures in a fresh table, in which (except for those who are colour-blind) the negative departures might be given in red ink and the positive in black.

8. In this table, at the right of the twenty-four departures for the various hours of the day, I should represent the mean departure for that whole day either in red or black. It would thus be seen, at a glance, whether the average of the whole day was affected by disturbance, in what direction, and to what extent.

9. It is here assumed that, during the month in question, no alteration of scale value or other instrumental change has taken place. Nevertheless at stations which have a considerable secular variation of declination, and for which this is known, it might be desirable to introduce, say to the extreme right, a column embracing a small residual correction, applicable to each day's departures, on account of secular change.

10. I imagine that a monthly table, constructed after the method which I have described, will afford a full and satisfactory basis for the discussion of disturbances.

11. It is probable that the smaller departures will follow the law of the ordinary solar diurnal variation, and, in that case, there should be as many *black* as *red* sums in these minor departures, or, in other words, the algebraic sum of these should be zero, while the sum taken without respect to sign or colour should represent the amount of oscillation or disturbance obeying the ordinary law, this being a point which it is of interest to determine. No doubt the larger disturbances will obey some other law, and it will be necessary to separate them into two categories, those *increasing* and those *diminishing* the declination. Here I should follow Dr. Buys Ballot's advice, and allow the observations themselves to determine where the one law ends and the other begins. It is just possible that sometimes the day's mean may be decidedly different from what it ought to be, and yet the diurnal variation for that day be as nearly as possible the same as for undisturbed observations. A table, such as that now described, will show, at a glance, whether such a state of things ever takes place.

Horizontal and Vertical Force.

12. The horizontal and vertical force magnetographs are different from the declination magnetograph, inasmuch as their indications are affected by change of temperature, by loss of magnetism, and possibly, in the case of the vertical force instrument, by other circumstances not well understood.

13. It will be noticed that, in treating the declination results by Sabine's method, we perform our operation upon the individual declination values. Now it might be said, why not (your object being to find the solar diurnal variation) take the departure of the individual hours of a day from the mean of that day, and treat each month's departures by Sabine's method?

14. The reply would be that the mean of a day is more likely to be affected by disturbance than the monthly mean of an hour. For disturbances, when they come, generally affect several consecutive hours, thus

altering the daily mean, but, on the other hand, they are less likely to affect the same hour during consecutive days. Were we able to obtain daily means of declination, unaffected by disturbance, it would be better to adopt this method of treatment, because it would obviate the introduction of any residual correction due to the progress of secular change or annual or semi-annual variation. Now in the force magnetographs the case is different. Here there is a certainty that some—perhaps even a considerable—change will be produced in the values belonging to a given hour in the course of a month from instrumental changes alone, so that treating the observations after the manner pursued with the declination might lead to erroneous results.

15. On the other hand, if there were no disturbance, the difference of the various hourly observations of a day, from the mean of that day, would give us a good indication of the solar diurnal variation, provided the diurnal range of temperature was inconsiderable, as is generally the case for self-recording instruments.

16. These remarks render it manifest that some method of obtaining probable values of the undisturbed daily means is, in the case of the force instruments, of vital importance, and Senhor Capello has adopted a method of this kind in his treatment of his force observations. I would venture to remark that the most unexceptionable basis upon which to determine the undisturbed daily means of horizontal and vertical force would seem to be given by the information already assumed to be obtained from the declination magnetograph for the same month.

17. Here, as a result of the application of Sabine's method, we have rejected a certain number of hourly observations as disturbed. Now let us reject, as a preliminary step to something more complete, precisely the same hourly observations of the horizontal and vertical force as being, in all probability, disturbed, and make use of the remainder, or of that part of the remainder which represents whole, or nearly whole, days free from disturbance, to aid us in determining, by a curve, the most probable values of the undisturbed daily means. I here assume that there is no sudden jump in the month's readings from change made on the instrument or any other cause; if there be such, the portions before and after the jump will have different values, and must be treated by appropriate methods which need not here be discussed. Suffice it to say that, by rejecting from the month's observations those hours which were separated as disturbed in the declination, and treating the remainder in the manner suggested, we obtain, aided, perhaps, by a slight equalisation, numbers representing very nearly the undisturbed daily values of the records given by the instruments.

18. Having obtained these, our next operation is to obtain the hourly differences from each day's undisturbed mean. These differences, so obtained, we propose to treat in the same manner in which we treated actual declination observations. It is, therefore, to *these differences* that Sabine's process should be applied, so that ultimately, when we have applied it, we shall obtain those departures of each hour from the daily mean which characterise undisturbed observations—in other words, we obtain the solar diurnal variation.

19. Having obtained this, we have at once the means of obtaining a table similar, in all respects, to that which we have recommended for the declination. For instance, if the departure of a given hour of a given day from the undisturbed mean of that day were +9 whereas, according

to the solar diurnal variation for undisturbed observations, it should have been +3, the number +6 would be inserted in the table, and so on.

20. It will be seen at once that we shall be able to ascertain by the method now described, if disturbance (as Broun supposed) alters the daily average values of the horizontal force. For in the horizontal force instrument any comparatively short period change of average daily value is hardly likely to be caused by instrumental alteration, but is most probably due to magnetic causes, more especially if the same change takes place simultaneously at various stations.

There are, however, more serious difficulties connected with the vertical force instrument, but into these I cannot now enter.

II. By Sir J. Henry Lefroy, K.C.M.G., F.R.S.

1. The statement of the question appears to assume that the first, or chief, object of continuous automatic registers of magnetic changes is to extend the large number we already possess of mean determinations of solar-diurnal variations, and to add fresh numerical or quantitative values of the deviations from these means, produced by the causes we class as irregular.

2. This appears to me to be persevering in a path we have been travelling for forty years without reaching, or even seeing the way, to any physical explanation of the phenomena.

3. There are about seventy-five points on the globe at which the diurnal variation, including disturbances, has been determined by eye-observations, hourly or bi-hourly, with more or less completeness and precision. The irregular, or non-solar-diurnal, effects have as yet been eliminated for a few only (ten or twelve) of these points, but this number has proved sufficient to bring out pretty clearly certain general laws to which no key has yet been found.

4. Unless it can be shown that a multiplication of numerical data promises to bring us to a conclusion, I am inclined to think that the laborious compilation of more data of the same kind by measurements from photographic registers, which are less precise than the old eye-observations, is rather a misdirection of energy, unless indeed at stations widely remote from any others, and where new facts may be expected (see, for example, the very anomalous diurnal curve at Reikiavik, Iceland, 'Athabasca volume,' p. 297). The recent circumpolar stations would have come into this category if they had used self-recording instruments.

5. Airy and Sabine have both taken $\pm 3'{\cdot}3$ of declination as the measure of a disturbed observation at Greenwich and Kew respectively.[1] If it is true, as remarked by Professor Balfour Stewart (par. 5), that the precise measure is of no great consequence, is it worth while to spend much time over making out a new value independently for any part of Great Britain?

6. The arbitrary nature of Sabine's mode of treatment of observations is to me a strong objection to the continuance of it.

For example, he threw out as disturbed all the observations at Point Barrow which deviated $22'{\cdot}87$ from the normal,[2] and at Fort Carlton[3] all which deviated $6'{\cdot}0$. But I think I have sufficiently shown that in high latitudes in America the mean value of disturbance is about three times

[1] *Phil. Trans.* 1860–1863. [2] *Phil. Trans.* 1857. [3] *St. Helena*, vol. ii.

as great in the early morning hours as it is in the afternoon. Consequently we must either disregard a great many observations by day, which are really disturbed, or include a great many by night, which are not, unless we say that instability is the same thing as disturbance.

7. What, then, is to be done with the photographic registers? How can they be compared unless by ordinates, measured at points agreed upon, such as the Göttingen hours?

I reply (1) that I think that each observer should minutely scan his own records, and note the time, direction, and amount of movements. (2) That the efforts of magneticians should be addressed to the cheap publication and prompt interchange of the registers of each week, reproduced and reduced by photography to a uniform scale, say 15mm. to 1 hour, with a view to the discovery of periodically recurring movements of whatever nature; of movements apparently local, or not generally traceable; and of movements which were general, in one or more elements, over a large part of the earth's surface.

It hardly meets this suggestion to say that we have hundreds of projections of disturbances already, and that nothing has come of it. It is true; but these projections are scattered through many volumes, are upon all sorts of scales, and are rarely comparative.

8. The student having by his eye-comparison grasped the general features of the movements constituting disturbance at some particular epoch, or presenting an exceptional character, the need of measurements would arise, and if a reference to the mean of the day or the mean of n days or of the calendar month is necessary, such mean can be ascertained. I am not sure that it often will be, and I doubt whether our adherence to the calendar month is rational. Why should movements on May 31 be referred to the mean for May rather than the mean for June? The more accurate, though more laborious, plan would be to refer them to the mean for May 31 $\pm$ 10 days.

9. The end of the needle which points to the equatorial region has in every locality a mean position in relation to the meridian from which it is continually deviating, and to which it always returns. It appears to me open to question whether the relation of the direction of the movement to the absolute declination, as increasing it or diminishing it, has much to do with the question. At least it seems to assume that the normal position is due to the same physical causes as produce the deviations, and therefore I think that the deviations, whether of the polar or equatorial end, should be simply noted as east or west without regard to sign. In the southern hemisphere it is the equatorial end that we observe. Regions where the north end is actually directed to the south, as at Port Kennedy and the *Alert's* winter quarters (1875–6), will require negative signs.

10. It seems probable (1) that the mean position of the needle above referred to is always perpendicular to the direction of electric currents in the crust of the earth, or the atmosphere, or both, originating in a thermo-electric action of the sun on the meridian, and propagated north and south from the ecliptic; (2) that the position of the meridian of the place, in reference to the sun, determines the direction of the mean deviation of the needle from its normal position or the mean solar-diurnal movement, and that the amount is determined by a balance of forces still to be clearly defined. The amount is known at a sufficient number of stations to test any law laid down.

11. It appears that so long as the sun is above the horizon of the place, there is comparatively little disturbance. In other words, the hours most habitually disturbed are before sunrise and after sunset. It is true that disturbances, once originated, display themselves simultaneously at distant localities, irrespective of the hours of the day; but the above seems to give probability to a conjecture that they originate in that hemisphere from which the sun is absent, and on those meridians which are at the time in the condition of greatest mean disturbance.

12. Of known physical causes, the influence of sudden internal perturbations analogous to those which become perceptible to our senses, as earthquakes and the like, seems to me the most nearly to meet the observed facts. They cannot be due to any atmospheric cause. Nor is it very probable that anything extra-terrestrial, such as solar perturbations, can operate with such vigour and suddenness upon our electric circulation. That there is a sympathy or correspondence between seismic disturbance and magnetic disturbance has been often shown, but I am not aware that it has ever been followed up in a comprehensive way.

That this view implies some relation between the internal perturbations referred to, and the position of the part of the globe in which they originate in respect to the sun, as being in the hemisphere turned away from him, appears to follow, but I do not see any absurdity in such a supposition.

13. Since continuous automatic registration affords a means of tracing the correspondence of either short-time or long-time movements with other observed phenomena, seismic movements, solar outbursts, auroral discharges, and atmospheric changes, for example such as no multiplication of eye-observations can do, this appears to me the first use to put it to. Forty years of eye-observation have added enormously to our store of facts, but brought us little if anything nearer a theory. Is it not time to try some other line of investigation?

14. With respect to the behaviour of the horizontal component during disturbances, depending as it does upon two variables, the dip and total force, it is rather unsatisfactory, but we have good and extensive data, and whatever principle of measurement or solution is applied to, the declination, must, I apprehend, be extended to this element.

15. With respect to the vertical component I doubt whether the available data are as yet comparable in precision with those of the other two elements. I saw, however, some admirable curves at Toronto, produced by Professor Carpmael's new instrument (I feel doubtful now whether they were curves of Δ Y or $\Delta\theta$), which had all the character and freedom of those of the horizontal force, and when these have been worked up and discussed we shall know a good deal more about the influence of disturbances in increasing or diminishing the dip and total force.

III. By Professor Schuster, F.R.S.

I should like to submit to the Committee a few points to which their attention, in my opinion, might with advantage be directed.

It is now nearly fifty years since Gauss applied the method of expansion in spherical harmonics to the elements of terrestrial magnetism. He considered his results only as preliminary, on account of the incompleteness of the data on which he had to work.

We possess now so much more information on the mean value of the terrestrial elements at different places, that, it seems to me, a repetition of the calculations of Gauss would lead to valuable results. Such a calculation would not only be of theoretical importance. For we might in this way detect many points of interest, as, for instance, where if anywhere masses of iron are present near the surface of the earth in sufficient quantity to affect the magnetic elements. At such places we should expect the harmonic analysis to give correct results only if extended to a large number of terms, so that if we confine ourselves, like Gauss, to four or five terms only, and find considerable differences between the calculated and observed values at some part of the earth's surface, we should have our attention specially directed to that part.

It is only by a reduction such as that of Gauss that we shall be able to find out where we require further observations, and where a multiplication of observations is unnecessary.

It would be very desirable if we could extend the analysis of spherical harmonics to the daily variation of the elements and to magnetic disturbances generally. But it seems to me that if, as is likely, these changes are due to electric currents either above or below the earth's surface but near it, the analysis would have to be carried to a large number of terms before it would yield satisfactory results. But this, of course, is a matter which the actual calculation only can settle, and we ought therefore, at any rate, to make the attempt to apply the method of Gauss to the daily variation. With our present knowledge of that variation at different places of the earth's surfaces, there ought to be no difficulty in finding out whether five or six terms are sufficient to represent it, taking account, of course, also of those terms which have their origin outside the earth.

Some observations of Sabine made near the magnetic pole[1] seem to point to the fact that part of the diurnal variation is due to a vertical component of an electric current crossing the earth's surface. Whether such a vertical component exists can be determined without difficulty, for we can actually measure it by taking the line integral of magnetic force at a given time over a closed curve on the earth's surface.

I should like, therefore, to propose to the Committee to find out, in the first place, what determinations of the magnetic elements ought to be taken account of in the reductions. In countries where we possess a great number of accurate data, it would seem only an increase of labour to take account of all of them. On the other hand, where we possess few measurements we should in all probability have to use even approximate determinations. It is a point for the Committee to decide whether we ought to take the places which are to be included in the calculation spread as evenly as possible over the earth's surface, or whether a preponderance should be given to places near the magnetic poles or at other places of special importance. Also whether the more accurate observations ought to be weighed. Should the Committee approve of these reductions, it would be well to ask at the next meeting of the Association for a sufficient grant to engage the assistance of one or two computers.

I should like in conclusion to submit a few observations respecting the remarks made by Professor Balfour Stewart and Sir Henry Lefroy. The function of the Committee seems to me to be a double one. In the

[1] See *Encyclopædia Britannica*—Terrestrial Magnetism (art. Meteorology).

first place, they are to discuss the best methods of reducing magnetic observations; but, before these methods can be put into execution, we must secure that the observations taken at different places are sufficiently homogeneous to admit of a common treatment. As we have to deal not with the individual observations, but with numbers which have already been reduced at the different observatories, it is clearly of importance that these preliminary reductions should be done everywhere in the same manner. Professor Stewart's suggestions refer exclusively to this point, while Sir Henry Lefroy rather discusses the question as to how the measurements already in existence can be made to yield information of physical value, and as they are treating of different matters, there does not seem to me to be necessarily any real difference of opinion between them. While agreeing entirely with a great many of the remarks made by Sir Henry Lefroy, I believe that some common method of reduction like that proposed by Professor Stewart is necessary before we can gain any knowledge of magnetical disturbances. With regard to the proposals themselves, the principal question will always be, whether the different heads of observatories can be made to agree on a uniform plan. The exact nature of the method of reduction is a matter which has to be settled chiefly by those who have practical experience in magnetic observatories.

The method of rejecting disturbed observations, commented upon by Sir Henry Lefroy, is, no doubt, open to objection. If it was simply our object to gain information on the *mean* value of magnetic elements, no observation however much disturbed ought to be rejected; but as soon as we suspect that the *mean* value is not the *normal* value—that is to say, that disturbances act more frequently in one direction than in another—we are necessarily driven to adopt some method of rejecting disturbed observations. The objections raised by Sir Henry Lefroy against the particular method employed by Sabine seem to me to be, however, very serious, but I can see no difficulty in amending that method so as to render it free of the difficulty.

IV. *Letter from Professor G. H. Darwin, F.R.S.*

Cambridge:
June 10, 1885.

A priori I should not have thought of distinguishing between mean and normal values, but I suppose that it is desirable to do so. It is obvious that if all the observations for a month are analysed, we get the mean harmonic constituents. Then if we recompute the values with these constituents (which may be done with a tide predicter), and subtract the hourly values from the observations originally analysed, we get a series of residuals. Supposing from those residuals we arbitrarily cut out a certain number which are above some arbitrarily chosen magnitude, and submit the rest to harmonic analyses, and supposing these present us with a new series of constituents with pretty constant phases and amplitudes, then it would seem to me that we should be justified in the hypothesis that normal and mean are not the same thing. I must suppose that some process more or less equivalent to this has been carried out.

I do not observe that any proposal is made to submit the monthly constants derived from harmonic analysis to a further analysis, and thus to derive the annual, semiannual, and terannual inequalities of the con-

stituents. My meaning is that we ought to express the result in sets of terms of this form.

$$\left.\begin{array}{l} A_0 + A_1 \cos\theta + A_2 \cos 2\theta + \ldots \\ \quad + a_1 \sin\theta + a_2 \sin 2\theta + \ldots \end{array}\right\} \cos\phi$$

$$\left.\begin{array}{l} B_0 + B_1 \cos\theta + B_2 \cos 2\theta + \ldots \\ \quad + b_1 \sin\theta + b_2 \sin 2\theta + \ldots \end{array}\right\} \sin\phi$$

I had some time back a letter from Chambers at Bombay in which he says that he considers he has detected a lunar inequality. Now, unless this is certainly incorrect, is it not desirable to submit the quantities to analysis according to lunar time? I take it that your proposal as to spherical harmonic representation is to put the A_0, A_1, A_2, a_1, a_2, &c., as constants multiplied by spherical harmonic functions of the latitude and longitude of the place of observation. Gauss had, as I fancy, only considered the mean values in this way, and you are proposing to treat the diurnal inequality in a similar manner.

If much harmonic analysis is to be done, some form nearly like that used for tidal reductions would seem to be useful.

The chief complication of those forms consists in the fact that the tide-heights are taken at exact solar hours, whereas we want measurements taken also at mean lunar and a number of other kind of hours. All this is avoided in your case, unless indeed you carry out an analysis for the alleged lunar influence.

Yours sincerely,
G. H. DARWIN.

V. *Notes on the above Suggestions.* By Professor BALFOUR STEWART.

The suggestions of the Committee are invited upon the following points:

1. Do they agree with the suggestion of Dr. Schuster, that it is of importance to ascertain the solar-diurnal variation of the three magnetic elements at various stations of the earth's surface, with the view of treating these after the method of Gauss?

2. Assuming that observations made at stations near the magnetic pole need special treatment, do the Committee think with Sir Henry Lefroy that even in ordinary localities the method of Sabine is objectionable for obtaining a correct value of the solar-diurnal variation? As a good many declination observations have been treated by this method it is of importance to set the question at rest, and the suggestions of the Committee are invited as to the best means of doing this.

3. What do the Committee think of the herein-recorded method of obtaining the solar-diurnal variations in the case of the horizontal and vertical force instruments? I may state that a point of immediate scientific importance arises regarding the V. F. solar-diurnal variation, inasmuch as the observers at Lisbon and Bombay suspect that this, unlike the diurnal variations of the other two elements, does not vary with the state of the sun's surface. It would be very desirable to obtain conclusive evidence of this from other stations.

VI. *Remarks on Magnetic Reductions.* By Senhor Capello.

The method of the separation of the disturbances of the readings of the bifilar and the vertical force, of which I have sent a *résumé*, and the examples of the calculation of the last year, seems practical enough to me, although it will give some trouble. It has, however, retained the principal fault, the arbitrary nature of the quantity which constitutes the disturbance. To practise this method upon the hourly observations of the vertical force is not, I think, more difficult than upon the bifilar.

With respect to the vertical-force instrument of this observatory, I do not find it very inferior to the bifilar, except for some months on two or three occasions, during which the equilibrium position was not good, for the curves had shown a jumping motion; otherwise it has answered almost as well as the bifilar, notably in the three or four last years, where the coefficient of temperature is very much reduced by the adoption of a contrivance to compensate the effects of temperature.

Our photographs already embrace twenty-one complete years. The meteorological work, and the care connected with the administration of the observatory and the meteorological stations absorb the greater part of our time. The reductions of the magnetic observations are very much behind, and it would be difficult to advance simultaneously all the elements as they should be; therefore I think that it would be convenient to establish an agreement upon the work which by preference it is desirable to accomplish, and for what period for a general comparison. With regard to No. 7 of the suggestions of Sir J. H. Lefroy, I am entirely of his opinion, and I will add my ideas upon some researches that I think would throw light upon the causes of the disturbances.

1. In a paper by Messrs. Capello and B. Stewart ('Proc. R. S.,' January 28, 1864) upon a first comparison of the disturbances at Kew and at Lisbon, we have recognised that of the little and abrupt disturbances of three to five minutes' duration (which are called peaks and hollows), and which are seen simultaneously in the three curves, those of the declination and of the vertical force are in the same direction at Kew and in the contrary direction at Lisbon; that is to say, while the north end of the declination needle at Lisbon goes towards east the same end of the vertical-force instrument dips. The contrary happens at Kew, the north end of the declination needle going towards east, while the same end of the vertical-force raises itself.

Again, on the other hand, we have also recognised the agreement of the behaviour of the peaks and hollows of the declination curves at Kew and at Lisbon. Thus one vertical peak at Lisbon corresponds always to a hollow at Kew, and *vice versâ*. It would be interesting (1) to extend this research upon peaks and hollows further; that is to say, between more distant observatories, employing the utmost rigour possible in the time-measures, in order to recognise if the times of the appearances of the peaks are absolutely the same, or if there is a sensible difference in the most distant observatories. (2) Again, we ought to look in some observatory immediately between Lisbon and Kew in order to see if the vertical-force peaks correspond sometimes to the peaks, sometimes to the hollows of the declination.

2. For the study of the disturbances I think it would be necessary that each observatory furnished with magnetographs should make pro-

jections upon the plane perpendicular to the inclination-needle, of the movement during the disturbance of the dipping pole of such a needle supposed to be suspended without friction by its centre of gravity.[1]

This projection ought to be constructed by means of the declination variations ($\triangle d$) and those of the inclination ($\triangle i$); the first being multiplied by the cosine of the inclination ($\cos i$), in order to its reduction in the inclination direction.

The readings of the three curves being made at the time of the first meridian, chosen at intervals of 2 m., 3 m., or 5 m., according to the degree of precision which is desired, their differences are taken by comparison with the first reading, and these differences should be reduced according to the values of the coefficients. In combining the values of the movements of the vertical force and of the bifilar, we find by the known formula $\left(\triangle i = \sin i \cos i \left(\frac{\triangle Y}{Y} - \frac{\triangle X}{X}\right)\right)$ the variations of the inclination; these variations are projected upon the chart in vertical directions, having reference to the first reading, and those of the declination in horizontal directions, employing a convenient scale.

Here is an example:—Four hours of the disturbance of the 1st of February, 1881, 0 h. to 4 h. (time of Pawlowsk) at Kew, and Lisbon readings being at the intervals of five minutes.

It is noticed that all the movements are reproduced in the two figures. They are generally at great length, and now and then deformed at Kew and of different inclination by comparison with the horizontal line. All the movements at Lisbon and Kew are executed in the manner contrary to the hands of a watch. The aspect is *sooner at Kew.*

If we make a similar research upon other more distant observatories—for example, Pawlowsk and Toronto—the same movements are still remarked; but some aspects are completely deformed, the movements at Toronto being executed in the manner of the hands of a watch.

The measurements in these researches have been taken from the curves of a scheme of a study of Mr. Wild upon the disturbances of February 1, 1881.

VII. *Observations on Magnetic Reductions.* By Dr. H. Wild.

As Messrs. Balfour Stewart and Brito Capello in the 'Suggestions for the Committee on Magnetical Reductions,' as well as Herr T. P. van der Stok in the 'Communications of the International Polar Commission,' No. 109, have clearly shown, there are to be distinguished in the variations of the magnetic elements—1st, their normal daily periods; 2nd, the slow and constant changes which the absolute values of the days' means of these show; 3rd, the eventually different daily periods which

[1] I think that it would be possible to construct a very simple instrument which could well register by photography all such disturbances, which would make these researches less laborious, avoiding all the measures and reductions which are always laborious. Let a little needle be suspended conveniently by the centre of gravity, employing a thread of silk. In one point of this needle let there be a mirror perpendicular to its magnetic axis. A luminous slit might be made to fall almost perpendicularly upon the mirror, registering the movement in all the directions of the needle. In order that these movements should not be confounded and superposed, the registering cylinder should proceed by jerks from hour to hour, or oftener according to experience.

the deviations from the normal daily path show.[1] In how far we are to conceive of the two last variations as disturbances must, in my opinion, be decided by experience.

In any case we require, for the fixing and estimation of these last variations, a distinct starting point, which the normal daily path may present.

It is, therefore, specially important here to establish this normal daily path of the magnetic elements. Now regarding the method which Sabine has devised for this, and also used so much, there is, in the first place, displayed what Lefroy, Weyprecht, and others have made so prominent, the arbitrary nature of the limits which are assumed for the expulsion of the so called disturbed data. Among the different proposals which have been made for a rational fixing to these limits the most worthy of notice is that of Buys Ballot, in which these limits are to be set where the deviations begin to show another period. Van der Stok has distinctly modified the Sabine method for the discovery of the normal daily path. His altogether very complicated method suffers, in my opinion, from the same wide evils as the Sabine method, viz., that it proceeds from the daily paths, derived, like them, from the sum of all observations without distinction, i.e. including disturbances. Now it is evidently, as Weyprecht has already shown, impossible out of the so procured data to get rid altogether of the influence of the disturbances on the normal daily path, if these are not quite irregularly distributed over the day, but are all subject to a certain daily period. Lefroy again, in his working out of observations at Fort Simpson and Lake Athabasca, has not employed all the data for the deriving of the first hour's means, but only the days and hours which, according to him, were not to be regarded as disturbed, i.e. where the amplitude of the movements does not go beyond a certain limit. The fact that the exclusion of these movements is not settled through the criterion of Buys Ballot on the one hand, as well as the consideration, on the other, that days with not less amplitude of movement may also be disturbed, because the disturbed periods might unite with the normal periods, so as to weaken themselves through interference (which, as we shall see, is partly the case), prevents the method from being satisfactory. In the Programme and in the Sittings of the fourth International Polar Conference in Vienna (April 1884) I have given out and developed a new method for the derivation of the normal daily path of the magnetic elements (see 'Communications of the International Polar Commission,' No. 94, p. 199; No. 97, pp. 208, 211; No. 98, pp. 254, 255, 257, 258), which is supported by the observation that in the magnetograph traces, even at the epoch of maximum disturbances, in every month are to be found a number of days in which a quite regular, and also as regards these days concerned a recurring periodical path is distinctly recognised.

I regard these days as days with undisturbed daily paths, and the hourly means of all these days as representative of the normal daily path of the elements concerned in the month in question, according to its relative as well as to its absolute size. The selection of these normal days may from the first likewise seem very arbitrary; in practice, however, this is not the case, as hardly a doubt can arise as to which days are to be taken, and besides the result will not be very distinctly different whether one chooses one or two days more or less, if from the first one

[1] For the sake of simplicity I have spoken here only of the daily periods; clearly for the remaining periods also, which show the variations of the earth's magnetism, suitable distinctions can be made.

only takes the precaution to eliminate through linear interpolation any sudden and individual disturbances which in such days at times show themselves. The differences of all the observed data from the so obtained values of the normal daily path in each month I regard as deviations from the normal, effected by some disturbing circumstances. Should, *e.g.*, all these deviations for all hours' values be put in the form of a table, and should each be distinguished as positive and negative, either by certain signs or, according to Balfour Stewart, by different colours, we should recognise at once, from the similarity of the signs and the nearly similar size of the figures, whether a day was disturbed uniformly positive and negative, and from the recurrence of the positive figures at certain hours, and negative in certain other hours on different days, whether the disturbance points to a new period different from the normal daily periods. In order to establish these conclusions with numerical correctness, it is best to group the deviations according to their extent, separating negative and positive, and then to investigate their periodicity as Buys Ballot has proposed.

Herr D. Müller has worked out according to these principles the jottings of the magnetograph in the Observatory of Pawlowsk for the period of the International Polar Expedition, August 1882 to August 1883. His important results have been laid by me before the Imperial Academy of Science, May 21 and June 2, 1885, and are at present published in the 'Repertorium for Meteorology.' Without entering into the details of Herr Müller's results, I only remark that the success of the first attempt seems to speak well for this method. The course of the contained normal daily path in the separate months has unexpectedly become regular for all three elements—declination, horizontal and vertical intensity, and also for inclination and total intensity. The days' means of the normal days show proportionally small differences, and only the greater deviations have a pronounced different periodicity, which again is different for the positive and negative. Herr Müller has therefore only pointed out the latter as disturbances, and the former as simple oscillations about the normal path. For two months, October 1882 and March 1883, I have prepared a comparison of Sabine's method for the declination with that got by Müller from my method. Here, in the calculation according to Sabine, $\pm$ 2 is assumed as the limiting value for the expulsion of disturbances; and these operations for individual hours were repeated as often as eight times. In spite of this, there is shown by a glance at the enclosed table that even by the Sabine method the influence of the prevailing positive disturbances late in the forenoon, and of the maximum of the negative disturbances in the afternoon, could not be eliminated from the result. I have the intention to get worked out according to this new method, which, in short, is applicable to all these data, certain traces of magnetographs in St. Petersburg and later in Pawlowsk from 1870, and have for this purpose for the whole period chosen the normal days out of the photograms.

From this came the unexpected result that the number of these at the time of the minimum of the sun spots is not so much greater than at the time of the maximum.

Table referred to by Dr. Wild.

Solar-diurnal Variation of the Declination in Pawlowsk.

Göttingen time	0^h	1^h	2^h	3^h	4^h	5^h	6^h	7^h	8^h	9^h	10^h	11^h	Mid-day 12^h	13^h	14^h	15^h	16^h	17^h	18^h	19^h	20^h	21^h	22^h	23^h	
October 1882	42·9	36·6	44·5	43·5	44·4	44·3	43·4	43·1	43·1	44·6	47·0	48·1	48·2	48·6	47·2	45·8	44·1	43·7	43·8	42·6	42·2	40·7	41·5	43·0	All observations

VIII. *Letter from Sir Frederick Evans to Professor Stewart.*

21 Dawson Place, Bayswater, London, W.:
May 9, 1885.

Dear Professor Balfour Stewart,—I shall be glad to render the Magnetic Committee all the assistance in my power, but I have been much out of sorts in my health for some time, and cannot so well undertake any work requiring much application.

On Tuesday I leave London for a few days, and will take the papers with me you forwarded on the 6th instant.

Until we see our way more clearly, it is the discussion of the disturbances of the Declination needle which appears to me the most important to break ground upon. On a clear insight of the probable laws at a few selected stations in both hemispheres, a discussion of other elements might well follow. Too grand a scheme and complicated methods of research would, I fear, break down. Sabine's methods had, at least, simplicity to recommend them.

A letter to the above address will reach me.

Yours faithfully,
FREDK. JNO. EVANS.

IX. *Letter from the Astronomer Royal to Professor Stewart.*

Royal Observatory, Greenwich, London, S.E.:
July 8.

Dear Prof. Stewart,—The printed suggestions for the Committee on Magnetical Reductions arrived at a very busy time, and since then I have been away from home; hence the delay.

As there is some difficulty in discussing abstract questions, I think it would save misunderstanding if you would make your suggestions with reference to our Magnetical Results for 1883, now in the press, of which I send you a copy. There are several additions and alterations which I have introduced in consultation with Mr. Ellis, in order to give as much information as practicable about the magnetic curves. We now give, in addition to mean values of the magnetic elements for each day and the mean diurnal curves for each month, the daily range, *i.e.*, the amplitude of the diurnal curve for each day, and particulars of all disturbances, small as well as large (either in the notes or in the plates). Harmonic analysis also has been applied to the diurnal variations for each month and for the year.

Now the question is, how far the suggestions of the Committee are carried out in the results given. As for rejection of disturbances, I am inclined to agree with Sir Henry Lefroy in his objection to Sabine's mode of treatment. At Greenwich the practice has been to draw a pencil curve smoothing down the irregularities of the trace, and to reject as disturbed those days for which a *continuous* pencil curve, agreeing generally in form with the normal curve, could not be drawn through the trace. I see no reason to modify this.

Yours very truly,
W. H. M. CHRISTIE.

X. *Letter from George M. Whipple, Esq., to Professor Stewart.*

Kew Observatory:

July 29, 1885.

Dear Prof. Stewart,—I have carefully read the paper you were so good as to forward to me, 'Suggestions for the Committee on Magnetical Reductions,' and must confess that I am in most points fully in accordance with Sir H. Lefroy.

I would much rather trust to the solution of the various problems of Terrestrial Magnetism by a farther and more extended series of comparison of curves than by an extension of numerical processes.

The reduction of the Fort Rae observation shows how enormously large and frequent the variations may be in some parts of the earth; and such being the case, I fail to see how any useful purpose could be served by the repetition of the calculations of Gauss.

I think that magneticians should endeavour, if possible, to enter into communication with geologists and seismologists, and endeavour to trace out clearly the causes of (what I would term) superficial variations, probably due, Prof. Schuster says, to electric currents, for localities well furnished with magnetic observatories, such as Europe, rather than to attempt at once to solve the whole problem of distribution throughout the earth of magnetic matter. I am, yours faithfully,

G. M. WHIPPLE, *Superintendent.*

P.S.—I enclose also copy of some remarks addressed by Capt. Dawson and myself to the Vienna Congress on the subject.

Further and additional remarks on the questions to be submitted to the Vienna International Polar Conference.

We are of opinion that careful inspection of the observations themselves will suffice to show the days and hours when the diurnal curve follows its normal course. From days and hours selected by this inspection, mean curves may be obtained, and ultimately by interpolation a series of hourly values may be arrived at for every day in the year.

Readings differing from these values by more than a certain separating value should be set aside and discussed as disturbances. It appears to us probable that the principle of determining the mean monthly diurnal curves for each station from observations selected only on such days as are shown by evidence of magnetographs elsewhere to have been magnetically calm, assumes beforehand a uniformity of magnetic conditions over the globe, and might, therefore, fail at certain stations. A rough comparison of Fort Rae and Kew Observatory results indicates to us that it is rather more advisable to deal with hours and not with days as a whole, and that therefore some rule, either Sabine's or Lloyd's, must of necessity be adopted.

There seems no objection to the application, first, of Lloyd's rule to throw out disturbances, and then to the subsequent classification of these disturbances after the method suggested by Wild.

We fail to see as yet any method of introducing possible corrections for sun-spot periodicity into observations made during so short an interval of time at stations where no previous observations have been taken; and therefore recommend that this disturbing element be omitted entirely

from the proposed international discussion, and left entirely to specialists for subsequent treatment.

With regard to the discussion of disturbances, we would suggest that each expedition should draw up a list of the days, selected according to Göttingen time, considered by them a disturbed day, and then from a comparison of such lists the Conference should decide on what days should be selected for particular discussion in addition to the term days.

Question 3.—Dr. Wild's suggestion as to plotting the curves is so very convenient that we have already adopted it in making preliminary curves of the Fort Rae observations. It will be necessary in addition, however, to decide upon the scale of abscissæ to be used for the 20-second interval observations on term hours. We suggest the employment of a scale giving six minutes of abscissæ to each minute of time.

Questions 4 *and* 5.—The conversion of Gaussian units into those of the C.G.S. system is so simple that it is unnecessary for the Conference to disturb the existing historic system. The Kew Observatory has already for years published their results in both systems. The foot-grain system is rapidly becoming obsolete, most magnetometers now constructed having mètre instead of foot scales.

XI. *Letter from General Lefroy to Professor Stewart.*

82 Queen's Gate, S.W.:
July 15, 1885.

My dear Professor,—I have carefully read, and return herewith, the papers of Senhor Capello and Dr. Wild. I have difficulty in attaching a physical idea to the ingenious method of projection proposed by Senhor Capello. He gives the movement, projected on a plane perpendicular to the dip of the axis or intersection of the plane of dip and the plane of declination; but I do not see how the variations of total force are to be shown in conjunction with this, or with what physical notions to connect the resulting curves. The actual realisation of the suspension of a needle by its centre of gravity without friction in any direction, especially if counterpoised to carry a mirror, would be a great achievement, but, with great respect, I doubt its being possible. Still his comparison of Lisbon and Pawlowsk is very curious, and strongly confirms my belief that, be our stations few or many, the results at *all* of them must be brought into one view, by identity of treatment and prompt circulation, to obtain a clue, and to effect this we want a *Deus ex machina.*

My file of bulletins of the International Polar Commission does not go beyond Part 5. I have not seen Herr van der Stok's communication, which Dr. Wild refers to. It has occurred to me, following a hint of Lloyd's,[1] that the *area* of movements would be a good measure of the forces producing them, and that it might be possible by an instrument on the principle of Amsler's planimeter to integrate these areas for the whole twenty-four hours, or any not very small portions of it, in moderate disturbances. The extremely active ones would not be easily measurable. To take cognisance, as has sometimes been done, of those movements only which coincide with hours of mean time or Göttingen time, appears to me to forego the special advantages of continuous record. I agree with Dr. Wild that there is no difficulty in selecting the normal days at

[1] *Trans. R.I.A.*, vol. xxii.

any station, but whether they would be the same at other stations has not, as far as I know, been ascertained. Lloyd, as you know, worked out the consequences of adopting every possible value of disturbance test. Sabine has given two or three values, all purely empirical. If my plan of *areas* were practically feasible, it does seem to me free from that objection. Dr. Wild appears to disregard magnitude, and to refer *all* the observed data to his normal values, and I think nothing less comprehensive will be found satisfactory in the long run. It is gratifying, however, to find that his results are not widely different from those obtained by Sabine's method. As Dr. Wild quotes Toronto, I suppose that some limited circulation and occasional comparison does go on, but Carpmael has no staff to keep it up regularly. We all want more hands, which means more money.

Believe me faithfully yours,
J. H. Lefroy.

XII. *Observations, &c.* By Charles Chambers, F.R.S., Superintendent, Colaba Observatory, Bombay.

There can be little doubt that the activity displayed during the last quarter of a century in the record of the phenomena of terrestrial magnetism was induced mainly by the interesting results to which Sabine was led in his discussions of the observations of the British, colonial, and other observatories; that it was in the hope of extending and completing *such* results by wider observation, that men of science in all parts of the civilised world urged upon their respective Governments the advisability of establishing magnetical observatories. Few who have studied Sabine's memoirs—displaying, amongst other remarkable generalisations, the outlines of a system of the globe in respect of the regular solar diurnal variations and the variations of these with the season of the year, and connecting with the sun-spot period variations of the range of the regular diurnal variation of declination and of the aggregate amounts of disturbance—will doubt the wisdom of the influence thus brought to bear on the guardians of the public purse, nor, whatever else may be done, of the propriety of carrying the work to the legitimate conclusion of extending and completing Sabine's results. To act otherwise, in the absence of a physical theory to which there is as yet no clue, would be to admit a change of judgment which there is nothing in the circumstances of the present day, any more than there was at the time when the work of automatic registration was initiated, to justify, and would, moreover, be to discourage the statesmen who, by the provision of funds, have aided in the production of records of the crude phenomena, from making further sacrifices in that direction: these dignitaries would, in their capacity of trustees for society, rightly complain that they had been led to expect systematised knowledge, but had been given instead piles of records of unused facts, and that the responsibility and expense of preserving these is scarcely a substitute for the reward they had been dazzled with the promise of.

2. In my opinion the scientific authorities, on whose advice much money has been spent in procuring many years' continuous records, are bound in honour to see that the representations which induced the various Governments to provide funds are justified by at least a full carrying out

of the original purposes as to the uses to which the records were to be applied.

3. The fact is that funds have been expended too exclusively upon material appliances, and upon agency for working them: the statesman can understand that his country gets a tangible return when observatory buildings, instruments, operators, records, and reports appear before him as a result of the grants that he makes; but it is for the man of science, the original adviser, to make him understand that these are very delusive results unless supplemented by appropriate measurement, computation, and discussion.

4. And this is the more important inasmuch as the cost of utilising the records, even up to the point suggested by Sabine's examples, will at least equal the amount that has been expended in their production. It is indispensable that inexpensive measuring, copying, and computing power should be used, under skilled direction, on a large scale; and here it is that the main part of the cost arises. It would be simple waste of superior energy to set a cultivated physicist to the appalling task of performing the simple but multitudinous series of operations that are involved in any adequate treatment of the observations; and it is to the insufficiency of suitable agency in the working power of existing observatories that is probably to be attributed the fact that so little has yet been done in the way of independent reduction and discussion of the records of the automatic magnetic instruments. That the work before us is laborious and costly is, however, no argument against the undertaking of it if we have reason to believe that an adequate return will be obtained; and a more costly process is to be preferred to a less costly one if the quality of the results that are the outcome of it is higher in a corresponding degree.

5. I cannot but think that the wonderful progress made during the last century in the experimental sciences is apt to make us unduly impatient of the necessarily slower progress of the observational sciences. If astronomy had, during the progress of observation, to have its period of phenomenal generalisation—its Ptolemy, its Copernicus, its Kepler—before light as to the mode of physical causation dawned upon its Newton, is it much to be wondered at that a much more complicated science, as terrestrial magnetism undoubtedly is, should have to pass through its period of discovery of general phenomenal relations—relations which the physical theory will ultimately have to explain—before the conditions essential to the conception of a general theory can be laid down?

6. It will be seen that whilst I have no faith in the flights of genius that would look at the crude facts as nature presents them to us, and from such complex data devise a theory to unravel the complexity, I have the greatest confidence in appropriate methods of analysation as leading to relatively simple phenomenal generalisations, and thence, inevitably in the long run, to the desired physical theory. The first step to be taken should, I think, be to collect together all accessible results that have already been worked out and published of the nature of—

(1) The regular solar-diurnal variations;
(2) The disturbance variations—diurnal, annual, and secular; and
(3) The lunar-diurnal variations;

and to convert the expression of them for each of the elements, declination, horizontal force, and vertical force, as far as available, into metre-gramme-second or C.G.S. units of force. If not already done, the averages of

(1) should be calculated *for each month* from the separate results of all the years that are available, and curves be constructed to represent these average monthly variations according to time-scales and force-scales which would be marked on the curve-forms. It would be convenient that the curves should appear, for any one station, in a row, beginning with January, on a long narrow slip of thick paper, so that the sets of curves for any one station might be placed close under those of any other station for easy comparison. For preservation, the slips of paper would be kept in a portfolio, not bound into a book. Curves on a less elaborate scale, as would be suggested by the meagreness (or fulness) of the materials collected, might similarly be constructed on slips to represent the variations (2) and (3). Such series of curves, to the extent to which data for them would be found easily accessible, would, I imagine, constitute a conclusive answer to those who doubt the utility of extending investigation in the same direction; but, taking continuity of change of character of the variations in passing from place to place as a criterion of the value and importance of the results obtained, they would also serve the further purpose of suggesting whether and where Sabine's methods are exact enough, or to what extent the application of even more laborious processes of reduction would be justified. These curves should be lithographed on thick slips of paper, and distributed amongst the directors of observatories and other students of terrestrial magnetism; and, as little in the shape of description or comment need accompany them, the originals could be produced by agency of an order that should be readily obtainable, and that would require but little supervision, from some specialist member of the Committee.

The curves might, with advantage, be accompanied by a table of the absolute values of the elements declination, horizontal force, and vertical force for each station; and also by tables of ranges of the solar-diurnal variations of each element on the average of each full year.

7. It has been well established by Broun and myself that the so-called lunar-diurnal variation is a function both of the season of the year and of the age of the moon, and there is reason for believing that the bulk of the phenomena is really a part of the regular solar-diurnal variation, a part that reverses its character four times in the course of the lunation.

Now the adoption, by Sabine's process, of a uniform solar-diurnal variation for the whole of a calendar month, whilst perhaps accurate enough for the determination of the general character of the disturbance laws, leaves much to be desired when the object we are in quest of is a minute variation which has, in the case of the declination, a less range than a single minute of arc, and which is subject to variation of character with change of season. Here we require that a mean solar-diurnal variation should be calculated for each individual day, in order that the elimination of mean solar effect should be nearly complete; and knowing that either a part of the solar-diurnal variation, or the bulk of the lunar-diurnal variation, runs through a cycle of change in a lunation, the best period for which to calculate the daily means is a mean lunation, or the nearest *odd* number of mean solar days to a mean lunation—that is to say, twenty-nine days. The importance of this period should be kept in view from the first, whether or not there is any immediate purpose of investigating the lunar-diurnal variations, and my present object is not so much to advocate the inclusion of such investigations in the first general scheme of operations as to explain why the period of twenty-nine days

enters into modifications that I would suggest of the procedure proposed by Dr. Balfour Stewart in dealing with the horizontal force tabulations, but which modified process should, I think, be applied also to the declination tabulations.

It is not a general rule that the hours at which the bulk of disturbance occurs are the same for both the elements declination and horizontal force; and hence—though it is highly probable that disturbance of some degree in one element occurs on the same day as disturbance of another degree in the other—we cannot with safety allot the disturbances to identical hours.

8. First, I would substitute for Sabine's classification of disturbances as 'larger' and 'smaller,' a division into those that are without the limits set by the normal ± the separating value, and those that are within those limits; and instead of rejecting disturbed observations I would, at such step of Sabine's process for separating the larger disturbances, replace each disturbed entry by the same number *minus* the disturbance without the limits—as apparent at that stage. The disturbances without the limits would be separated and the laws of their variations determined by the methods that Sabine applied to his larger disturbances, but the disturbances within the limits would remain involved with the regular variations until a late stage of the investigations.

9. Secondly, as regards progressive change in the readings, both of the declination and horizontal force instruments, it would, I think, generally suffice to treat that change as uniform during the course of a month. Having entered the hourly tabulations for a given month on a table (A call it) having the hours marked at the top of the columns and the days of the month in the first or left-hand column, and having taken daily means, I would take the mean of the first fifteen of those daily means and the last fifteen of the preceding month's table A as the mean number for the beginning of the month; and similarly the mean number for the end of the month would be the mean of the last fifteen daily means of that month and the first fifteen of the next following month. Change at the uniform rate indicated by the mean numbers[1] for the beginning and end of the month I would eliminate from the original hourly tabulations of table A, and enter the new number on a new table (B), to which I would proceed to apply Sabine's (modified) process. This would lead to a general knowledge of the regular solar-diurnal variations for each month, and of the laws of the disturbance variations; and here a resting-place might be found if it were desired to compare results from different stations before proceeding with more elaborate reductions.

10. To proceed, however, I would next, having obtained the amounts of disturbance without the limits, eliminate these amounts from the respective disturbed observations of table A, calling the table thus altered (A′), and this table should form the basis of discussion in respect of the regular solar-diurnal variations for each day, the lunar-diurnal variations, and the laws of variation of disturbances within the limits.

From table (A′), and the corresponding table of the preceding and following months, I would construct another similar table (C), each entry in which would be the 29-day mean of the numbers for the same hour

[1] The effects of disturbances without the limits on the daily means I would take to be sufficiently indicated by the departures of those means from corresponding daily means, as calculated from the mean numbers for the beginning and end of the month, with a uniform rate of change from one to the other.

in table (A′), viz., of the numbers for the day of the entry and the fourteen preceding and fourteen following days. The numbers of table C for all the hours of a given day we may take to represent very approximately the mean solar-diurnal variation—*plus* a constant—for that day, the average extending over the lunation of which that day is the middle day. They will be affected by progressive change of the values of the tabulations, and by disturbance within the limits.

11. Lastly, the excesses of the numbers of table (A′) over the corresponding numbers in table C, *plus* a constant round number,[1] should be entered on a fourth table (D). The numbers of this table, which will be affected only by that part of the solar-diurnal variation which goes through a cycle of change in a lunation, and by disturbance within the limits, we may proceed to arrange in new tables with reference to the moon's age and the season (or month) of the year,[2] and so determine the character of the variations which the luni-solar-diurnal variation is subject to. Having done this, a further elimination will put us in possession of residual numbers, the variation of which must be attributed solely to disturbances within the limits, and may be studied and the numbers be manipulated accordingly.

12. I agree with Dr. Balfour Stewart that the time has not yet arrived for laying down rules for the treatment of the vertical force tabulations.

XIII. *Letter from the Rev. Professor S. J. Perry, F.R.S.*

September 8, 1885.

Dear Dr. Schuster,—I have read over the Report Dr. Stewart kindly forwarded, and I cannot help thinking that our first step should be to collect the results already obtained for the Daily Range of the Declination, reduce the means already worked out to a common scale, and then distribute the whole in a tabular and in a graphical form. Much might be learnt from seeing these results in a collective form, and we could then better judge how far processes more laborious than those of Sir Edward Sabine are like to repay the labour.

If all observations are made use of in deducing the Daily Mean Range the Disturbance period will certainly interfere with the Solar Diurnal Range, and if we pick out quiet curves in which the Daily Range is well marked, we are very liable to give undue weight to variations in the Daily Range which are independent of ordinary disturbances.

Yours very truly,
S. J. Perry.

[1] The constant round number is added to avoid the inconvenience of having to deal afterwards with *positive* and *negative* numbers.

[2] If a separate table be allotted to each day of the moon's age, the resulting mean variations will be practically the same whether the hours refer to the solar or the lunar day; and as the numbers available are for the exact hours of the solar day, it is convenient to let the arrangement of the table be for the solar day rather than for the lunar day.

Report of the Committee, consisting of Professor CRUM BROWN (*Secretary*), Mr. MILNE HOME, Mr. JOHN MURRAY, *and* Mr. BUCHAN, *appointed for the purpose of co-operating with the Scottish Meteorological Society in making Meteorological Observations on Ben Nevis.*

DURING the past twelve months the observations on Ben Nevis have been made every hour, by night as well as by day. This remarkable continuity in the observations, conducted under such great difficulties, is due to the enthusiasm and undaunted devotion to the work evinced by Mr. Omond and his assistants, and to the completion of the Observatory building last summer with its tower, which admits of a ready egress from the Observatory when the doors are blocked with rapidly accumulating snow-drifts, except during those rare occasions, of which the winter months of 1884–85 afforded only one example, in the great storm of February, when from 6 P.M. of the 21st to 8 A.M. of the 22nd no light could be carried in a lantern outside to the instruments. This interruption refers only to the observations of the temperature of the air.

During the year the most notable additions made to the observations refer to the rainfall and the wind. The actual precipitation—rain, sleet, snow, or hail—has been collected with rain-gauges specially designed for the purpose, and measured with the greatest care every hour since June 24, 1884, with, it is believed, a very close approximation to the truth; and the hourly results for each month have been calculated.

In the end of October the anemometers designed by Professor Chrystal for the Observatory, to register continuously the velocity and direction of the wind, were added to the observing instruments. Unfortunately, however, in the colder months of the year the deposition of ice-crystals, which Mr. Omond has described in a recent paper, renders all anemometers quite useless, except at rare intervals. During the seven months from November 1, 1884, to May 31, 1885, there was only a mean of thirty days in which the anemometer was in working order. During these days the greatest velocity was on the night of April 24–25, when for twelve hours the mean velocity was seventy-four miles, rising one hour to eighty-one miles.

Estimations of wind-force have continued to be made every hour during the year, and the results show, as in the previous year, that the wind is above the mean daily force during the night and below it during the day. The maximum occurred from 2 to 3 A.M. and the minimum from 2 to 3 P.M., the difference between the extremes being between two and three miles an hour. The means of the observations made since the Observatory was opened show that the same relation holds good during each of the four seasons. These peculiarities in the diurnal variation in the velocity of the wind on Ben Nevis are of the greatest importance, especially in view of similar curves obtained at other high-level observatories situated on mountain peaks, and by Mr. Archibald Douglas from his balloon observations and experiments, and their bearing on atmospheric movements.

During July 1885 the anemometers have been continuously at work, and there are now before us a month's complete hourly records of recorded velocities and estimated wind-force. The curves drawn from

the results of these two methods are closely congruent. This double set of observations supply the data for a more exact conversion of the estimations of wind-force, according to Beaufort's scale, into their equivalents in miles. A large number of similar observations made on board the *Challenger* also form a valuable contribution to this inquiry. So far as the observations go, they appear to indicate that the equivalents in miles usually given for the higher numbers of Beaufort's scale are too small. From 8 to 9 A.M. of August 9 the anemometer registered 86 miles, and during this hour the estimated force was from 8 to 9 of the scale. The equivalent in miles for this force, provisionally adopted by the Meteorological Council, is from 48 to 56 miles. What is the number of miles when an estimated force of 10 or 11, which has been not unfrequently recorded during the colder months of the year, is reached and maintained for some time remains to be seen. Instances will in all probability occur during the autumn before the ice-deposits of the wind practically seal up the anemometer for the winter months.

The mean temperature for the year ending May 1885 was 30°·6, or 0°·3 below the calculated normal temperature given in last year's Report. The temperatures for the same period for stations in the more immediate neighbourhood were from 0°·3 to 0°·4 below their normals, being thus identical with the deviation from the normal at the Observatory. The extremes of temperature for the year were 60°·1 at 2 P.M. August 9, and 11°·1 at midnight and 1 A.M. February 16, thus giving a range of 49°·0. The coldest week yet experienced was the week ending February 21, the mean of which was 16°·2. In this week the lowest temperature for the year occurred, and the humidity fell to 22. Great dryness associated with great cold scarcely ever occurs in the weather records of the Ben, and in this case the exceptionally cold dry weather terminated with the great storm of the 21st and 22nd February already referred to.

From the observations of the maximum and minimum thermometers the mean daily range of temperature is—in winter, 6°·8; spring, 6°·4; summer, 7°·1; and autumn, 6°·6—there being thus little variation with season. From the dry bulb, there is only 0°·7 between the mean coldest and mean warmest hour of the day in winter, but in summer the difference is 3°·0. It follows that in all seasons, but particularly in winter, the changes of temperature which occur are only in a subordinate degree due to the direct influence of the sun, but are chiefly caused by the passage of cyclones and anti-cyclones over the Observatory. Indeed, it may be regarded that, in the stormy months of winter, the Ben Nevis observations present the cyclonic and anti-cyclonic changes of temperature in their simple conditions, uninfluenced by the heat of the sun.

Lower relative humidities were observed than during the previous year. On January 20, the mean of the twenty-four hours gave the very low mean humidity of 32. On the 15th of the same month, at 5 A.M., the dry bulb was 20°·9 and the wet 16°·2, which from Glaisher's tables indicates a dew-point at −16°·2 and a humidity of 19, being respectively the lowest yet noted on the top of Ben Nevis. The lowest temperature ever observed anywhere in the British Islands was −16°·0, at Springwood Park, near Kelso, in December, 1879, which closely agrees with the lowest dew-point on Ben Nevis. As regards atmospheric pressure, it is only in winter that the afternoon minimum falls below the mean daily pressure; in summer this daily minimum is 0·007 inch above the daily mean. On the top of Ben Nevis, atmospheric pressure of the three seasons, spring,

summer, and autumn, is above the daily mean for fifteen hours, from 10 A.M. to midnight, and below it for nine hours, from 1 to 9 A.M. In June, when the sun's heat is most powerful, the afternoon minimum is the least pronounced, and the diurnal curve of pressure tends towards a single maximum and minimum, similar to what occurs in the same months over the open sea in the higher latitudes. Except in mid-winter these seasonal peculiarities of the pressure are seen in the results of each month's observations, and the regularity in the changes from month to month, in the times of occurrence of the four phases of the pressure, is very striking.

The sunshine-recorder shows 464 hours of sunshine for the twelve months, which is about 11 per cent. of the possible sunshine. As regards the partition of the sunshine through the hours of the day, the most noteworthy circumstance is that during spring, summer, and autumn the amount is very considerably greater before noon than after it. As compared with the afternoon, the sunshine of the forenoon is 43 per cent. greater in spring, 50 in summer, and 33 in autumn, whereas in winter the amounts are nearly equal. During summer the maximum sunshine occurs from 6 to 9 A.M. This diminution in sunshine later in the day is no doubt caused by the ascending aerial currents which rise from the heated sides of the mountain during the warm hours of the day, and the condensation of the aqueous vapour into cloud which is the consequence.

Very heavy rainfalls are of frequent occurrence on Ben Nevis. Of single hours the largest was 1·302 inch, from noon to 1 P.M. of December 10, 1884. The largest daily fall was 4·264 inches, on December 10, 1884, a fall all but equalled by that of October 25, which was 4·231 inches. A fall of at least one inch occurs, on the average, one day in seven. Combining all the rainfall observations made since June, 1881, the following are the averages; those from July to September being for four years, June and October for three years, and November to May one year only.

	inches		inches		inches
January	7·33	May	8·37	September	9·44
February	16·94	June	8·80	October	11·08
March	12·89	July	10·70	November	19·30
April	4·85	August	11·24	December	25·20

Year, 146·14 inches.

There can be little doubt that the Ben Nevis Observatory has the largest rainfall of any place in Scotland at which a rain-gauge has hitherto been observed.

The observations at Fort William by Mr. Livingston, consisting of eye observations six times a day, and continuous records of the atmospheric pressure and temperature by a barograph and thermograph, have been regularly carried on during the year. It is not possible to over-estimate the value of these sea-level observations at Fort William, in their relations to the observations made on the top of Ben Nevis, it being from these relations that the Ben Nevis observations have their supreme importance in discussing the great problem of the weather changes of North-western Europe. This inquiry is now being carried on under the superintendence of the Directors of the Observatory.

Seventeenth Report of the Committee, consisting of Professor EVERETT, Professor Sir W. THOMSON, Mr. G. J. SYMONS, Sir A. C. RAMSAY, Dr. A. GEIKIE, Mr. J. GLAISHER, Mr. PENGELLY, Professor EDWARD HULL, Professor PRESTWICH, Dr. C. LE NEVE FOSTER, Professor A. S. HERSCHEL, Professor G. A. LEBOUR, Mr. GALLOWAY, Mr. JOSEPH DICKINSON, Mr. G. F. DEACON, Mr. E. WETHERED, *and* Mr. A. STRAHAN, *appointed for the purpose of investigating the Rate of Increase of Underground Temperature downwards in various Localities of Dry Land and under Water. Drawn up by* Professor EVERETT (*Secretary*).

THE present Report is for the two years which have elapsed since the summer of 1883.

Observations have been taken in a deep bore at Richmond, Surrey, by Mr. Collett Homersham, M.Inst.C.E., F.G.S. It is on the premises of the Richmond Vestry Waterworks, on the right bank of the Thames, and about 33 yards from high-water mark. The surface is 17 feet above Ordnance datum.

The upper part consists of a well 253 feet deep, with an internal diameter of 7 feet at top and 5 feet at bottom, which was sunk in 1876 for the purpose of supplying water to the town of Richmond, and carried down to the chalk. From the bottom of the well a 24-inch bore-hole was sunk to the total depth of 434 feet, thus penetrating 181 feet into the chalk. This portion of the work was completed in 1877. Above the chalk were tertiaries, consisting of 160 feet of London clay, 60 feet of the Woolwich and Reading beds, and some underlying sands. The water yielded at this stage was about 160 gallons a minute, and when not depressed by pumping was able to rise 4 or 5 feet above the surface. Its ordinary level, owing to pumping, was about 130 feet lower.

In 1881 the Richmond Vestry determined to carry the bore-hole to a much greater depth, and the deepening has been executed under the direction of Mr. Homersham's father, who is consulting engineer to the Vestry.

The existing bore-hole was first enlarged and straightened, to enable a line of cast-iron pipes, with an internal diameter of $16\frac{1}{2}$ inches, having the lower end driven water-tight into the chalk at a depth of 438 feet, to be carried up to the surface. The annular space surrounding this pipe served to furnish an uncontaminated supply of water to the town during the deepening.

The total thickness of the chalk was 671 feet. Below this was the upper greensand, 16 feet thick; then the gault clay, $201\frac{1}{2}$ feet thick; then 10 feet of a sandy rock, and a thin layer of phosphatic nodules. Down to this point the new boring had yielded no water. Then followed a bed $87\frac{1}{2}$ feet thick, consisting mainly of hard oolitic limestone. Two small springs of water were met with in this bed at the depths of 1,203 and 1,210 feet, the yield at the surface being $1\frac{1}{4}$ gallons a minute, with power to rise in a tube and overflow 49 feet above the ground. A partial analysis of this limestone rock showed it to contain 2·4 per cent. of

sulphide of iron in the form of pyrites. At the depth of 1,239 feet this limestone rock ended, and hard red sandstone was found, alternating with beds of variegated sandy marl or clay. After the depth of 1,253 feet had been attained, the yield of water steadily increased as the boring was deepened, the overflow at the surface being 2 gallons a minute at 1,254 feet, 8 gallons at 1,363 feet, and 11 gallons at 1,387 feet. It rose to the top of a tube carried 49 feet above the surface, and overflowed; and a pressure-gauge showed that it had power to rise 126 feet above the surface.

The diameter of the bore was $16\frac{1}{4}$ inches in the chalk, $13\frac{1}{2}$ inches in the gault, $11\frac{1}{4}$ inches in the oolitic limestone, and at the depth of 1,334 feet it was reduced to a little under 9 inches. At 1,337 feet the method of boring was changed, and instead of an annular arrangement of steel cutters, a rotary diamond rock-boring machine was employed. The bore-hole, with a diameter of $8\frac{1}{2}$ inches, was thus carried down to $1,367\frac{1}{2}$ feet, at which depth, lining tubes having to be inserted, the diameter was reduced to $7\frac{1}{4}$ inches, and this size was continued to 1,447 feet, at which depth the boring was stopped.

The bore-hole was lined with strong iron tubes down to the depth of 1,364 feet; and those portions of the tubes that are in proximity to the depths where water was struck were drilled with holes to admit the water into them. Three observations of temperature were taken at the depth of 1,337 feet, during the interval between the removal of the steel borers and the erection of the diamond boring-machine. The bore-hole was full of water, which was overflowing at the rate of from three to four gallons a minute. The thermometer employed was an inverted Negretti maximum, supplied by the secretary. In each case the temperature recorded was $75\frac{1}{2}°$ F. In the first observation, March 25, 1884, the thermometer was left for an hour and a quarter at the bottom of the bore-hole, and three weeks had elapsed since the water was disturbed by boring. The second observation was taken on March 31, when the thermometer was $5\frac{1}{2}$ hours at the bottom. In the third observation special precautions were taken to prevent convection. The thermometer was fixed inside a wrought-iron tube, 5 feet long, open at bottom. The thermometer was near the lower end of the tube, and was suspended from a water-tight wooden plug, tightly driven into the tube. There was a space of several inches between the plug and the thermometer, and this part of the tube was pierced with numerous holes to allow the escape of any cold water which might be carried down by the tube. The tube was one of a series of hollow boring-rods used in working the diamond drill-machine. By means of these it was lowered very slowly, to avoid disturbance of the water as much as possible; and the tube containing the thermometer was gradually worked through the sand at the bottom of the bore-hole. The lowering occupied five hours, and was completed at noon on Saturday, June 7.

Cement, mixed with sugar, for the purpose of slow setting, was immediately lowered on to the surface of the sand, and above this a mixture of cement and sand, making a total thickness of 3 or 4 feet of cement plugging. The thermometer was left in its place for three full days, the operation of raising being commenced at noon of Tuesday, June 10, and completed at 5 P.M. The thermometer again registered $75\frac{1}{2}°$ F., exactly the same as in the two previous observations which were taken without plugging. It would therefore appear that the steady upflow of water in

the lower part of the bore prevents any downward convection of colder water from above.

The boring has since been carried to the depth of 1,447 feet, with a diameter reduced to $7\frac{1}{8}$ inches, and Mr. Homersham made preparations for a final observation at the bottom with a plug consisting of a thick india-rubber disc covered with cement and sand; but the vestry declined to incur the responsibility of having the rods lowered again for this purpose; and as some pieces of broken lining-tube had fallen in, there would have been serious risk of jamming. Mr. Homersham accordingly contented himself with lowering the thermometer to the bottom without plugging. It remained down for six days (February 3 to 9, 1885), and gave a reading of $76\frac{3}{4}$° F. The water overflowing at the surface had a temperature of 59° F.

To deduce the mean rate of increase downwards, we shall assume a surface temperature of 50°. This gives for the first 1,337 feet an increase of $25\frac{1}{2}$°, which is at the rate of 1° F. in 52·4 feet, and for the whole 1,447 feet an increase of $26\frac{3}{4}$°, which is at the rate of 1° F. in 54·1 feet. These results agree well with the Kentish Town well, where Mr. Symons found in 1,100 feet an average increase of 1° in 55 feet.

Mr. Homersham carried on a lengthened correspondence with the secretary as to the best manner of taking the observations, and the method devised by him as above described will furnish a useful model for future observers.

Thanks are also due to the Richmond Vestry for permission to observe, and to the contractors, Messrs. Docwra, for the loan of their apparatus.

Mr. Galloway (member of the Committee) has furnished observations taken during the sinking of a shaft to the depth of 1,272 feet in or near the Aberdare valley, Glamorganshire. The name of the place is Cwmpennar, and the position of the shaft is on the slope on the east side of the valley, near the summit of the hill which separates it from the Merthyr valley. The mouth of the shaft is about 800 feet above sea level.

Observations were taken at four different depths, 546 feet, 780 feet, 1,020 feet, and 1,272 feet, the thermometer being in each case inserted, and left for twenty-four hours, in a hole bored to the depth of 30 inches, at a distance not exceeding $2\frac{1}{2}$ yards from the bottom of the shaft for the time being. About eight hours elapsed between the completion of the hole and the insertion of the thermometer. The strata consist mainly of shales and sandstone, with a dip of 1 in 12, and the flow of water into the shaft was about 250 gallons per hour.

The first of the four observations was taken in the fireclay under the Abergorkie vein; the second in strong 'clift' (a local name for arena ceous shale) in disturbed ground; the third in bastard fireclay under a small rider of coal previously unknown; the fourth in 'clift' ground two yards above the red coal vein, which overlies the 9-foot seam at a height of from 9 to 12 yards. The observations were taken by the manager, Mr. John Beith, and are as follow:

Depth in ft.	Temp. Fahr.
546	56°
780	$59\frac{1}{2}$°
1,020	63°
1,272	$66\frac{1}{2}$°

Comparing consecutive depths from 546 feet downwards, we have the following increments of temperature :—

$3\frac{1}{2}°$	in 234 ft.,	giving 1° for	67 ft.
$3\frac{1}{2}°$	„ 240 „	„	69 „
$3\frac{1}{2}°$	„ 252 „	„	72 „

—showing a remarkably regular rate of increase. A comparison of the first and fourth observations gives an increase of $10\frac{1}{2}°$ in 726 feet, which is at the rate of 1° F. in 69·1 feet. As the surface slopes about 1 in 5, and the pit is near the summit of a ridge, it is probable that in level ground of similar material the rate would be about 1° F. in 60 feet.

As a check upon this result, we find that this rate of *decrease* reckoned *upwards* from the smallest depth (546 feet) would give a surface temperature of (56 − 7·9 =) 48°·1, which, as the elevation is 800 feet, is probably very near the truth.

Mr. Garside has sent an observation of temperature taken by himself in the roof of the Mersey tunnel in August 1883. The temperature was 53°, the depth below Ordnance datum being 92 feet. A great quantity of water from the river was percolating through the sides of the tunnel.

On August 13, 1884, he verified his previous observation in Denton Colliery (15th Report). The second observation was made at the same depth as the first (1,317 feet), in the same pit and level, and under the same circumstances, except that the thermometer was allowed to remain fourteen days in the hole bored for it, instead of only six hours. The temperature observed was the same as before, namely 66°.

Mr. Garside has also supplemented his previous contribution to our knowledge of the surface temperature of the ground in the East Manchester coal-field (16th Report) by two more years' results from the same observing stations. The following are the collected results, including the year previously given :—

Croft House, in the centre of Ashton-under-Lyne, 345 *ft. above sea.*

—	4 ft. Deep	1 ft. Deep	Mean of Max. and Min. Air
1882	47°·5	46°·2	48°·4
1883	46°·6	45°·5	47°·8
1884	48°·3	47°·3	48°·9
Means	47°·5	46°·3	48°·4

District Infirmary, 501 *ft. above sea.*

—	4 ft. Deep	1 ft. Deep	Mean of Max. and Min. Air
1882	45°·9	45°·6	46°·6
1883	46°·3	45°·3	46°·3
1884	47°·7	47°·3	48°·2
Means	46°·6	46°·1	47°·0

Giving equal weight to the 4-foot and 1-foot observations, we have a mean surface temperature of 46°·9 at an elevation of 345 feet, and 46°·4

at 501 feet. The difference between them agrees well with the generally accepted rate of 1° for 300 feet, and indicates about 48° as the surface temperature at small elevations, such as 30 feet. The pits in the East Manchester coal-field from which we have observations, namely, Astley Pit (Dukinfield), Ashton Moss, Bredbury, Denton, and Nook Pit, are all sunk in ground at elevations of between 300 and 350 feet. It would therefore appear that the assumption of a surface temperature of 49°, which we made in reducing these observations, is about 2° in excess of the truth.

A very elaborate paper on Underground Temperature has recently been communicated to the Royal Society by one of the members of the Committee—Professor Prestwich. It contains probably the fullest collection that has ever been made of observations of underground temperature, accompanied in most cases by critical remarks; and adduces arguments to show that most of the temperatures observed are too low, owing to the influence of the air in mines, and of convection currents in wells. Professor Prestwich is disposed to adopt 1° F. in 45 feet as the most probable value of the normal gradient.

Report on Electrical Theories.
By Professor J. J. THOMSON, *M.A., F.R.S.*

IN this report I have confined myself exclusively to the consideration of those theories of electrical action which only profess to give mathematical expressions for the forces exerted by a system of currents, and which make no attempt to give any physical explanation of these forces; for it is evident that before we can test any theory of electrical action we must know what the actions are which it has to explain, and we cannot do this until we have a satisfactory mathematical theory. I have further limited myself to the consideration of the fundamental assumptions of each theory, and have not attempted to give any account of its mathematical developments, except in so far as they lead to results capable of distinguishing between the various theories.

I have divided the theories into the following classes :—

1. Theories in which the action between elements of current is deduced by geometrical considerations combined with assumptions which are not explicitly, at any rate, founded on the principle of the Conservation of Energy.

This class includes the theories of Ampère, Grassmann, Stefan, and Korteweg.

2. Theories which explain the action of currents by assuming that the forces between electrified bodies depend upon the velocities and accelerations of the bodies.

This class includes the theories of Gauss, Weber, Riemann, and Clausius.

3. Theories which are based upon dynamical considerations, but which neglect the action of the dielectric.

This class contains F. E. Neumann's potential theory and v. Helmholtz's extension of it.

4. C. Neumann's theory.

5. Theories which are based upon dynamical considerations, and which take into account the action of the dielectric.

This class includes the theories of Maxwell and v. Helmholtz.

We shall now proceed to the detailed consideration of these theories.

Theories in which the action between elements of current is deduced by geometrical considerations combined with certain assumptions which are not explicitly, at any rate, founded on the Principle of the Conservation of Energy.

The best known theory of this class is that of Ampère. Others, however, have been given by Grassmann, Stefan, and Korteweg, which we shall consider in order.

Ampère's Theory.

This theory was first published in 1820. In 1823 appeared his great paper, the 'Mémoire sur la Théorie Mathématique des Phénomènes Electro-dynamiques,' *Mémoires de l'Institut*, t. vi., which Maxwell describes as 'perfect in form and unassailable in accuracy,' and which at once brought the action between electric currents under the power of mathematics. Ampère founded his theory on certain postulates which he attempted to establish by experiment; inasmuch, however, as he always dealt with closed circuits in his experiments and elements of circuit in his postulates, the experimental evidence is not quite satisfactory. Ampère's experiments have been repeated by v. Ettingshausen [1] with much more delicate apparatus.

The postulates used by Ampère are as follows. The first four are given in the words of Professor Tait:—[2]

I. 'Equal and opposite currents in the same conductor produce equal and opposite effects on other conductors; whence it follows that an element of one current has no effect on an element of another which lies in the plane bisecting the former at right angles.'

II. 'The effect of a conductor bent or twisted in any manner is equivalent to that of a straight one, provided that the two are traversed by equal currents and the former nearly coincides with the latter.'

III. 'No closed circuit can set in motion an element of a circular conductor about an axis through the centre of the circle and perpendicular to its plane.'

IV. 'In similar systems traversed by equal currents the forces are equal.'

V. 'The action between two elements of current is a *force* along the straight line joining them, and proportional to the product of the lengths of the elements and the currents flowing through them.'

It follows from IV. that the force between two elements of current varies inversely as the square of the distance between them.

The assumption V. is one that can only be justified by the correctness of the results to which it leads. We have no right to assume *à priori* that the action is equivalent to a single force, and not to a force and a couple; and we have no more right to assume that the force is along the line joining the elements than we have to assume that the force between

[1] 'Ueber Ampère's elektrodynamische Fundamentalversuche,' *Wien. Ber.* (11), 77, p. 109, 1878.

[2] Tait's *Quaternions*, 2nd edit. p. 249.

two small magnets is along the line joining their centres, and in this case the assumption is untrue. It is in the nature of the assumption V. that Ampère's theory differs from others of this class. The second part of I. depends upon V. It is not true unless we assume that the force between two elements is along the line joining them.

Ampère deduces the force between two elements of current from these principles in the following way:—Suppose we have two elements of current of lengths ds_1, ds_2 traversed by currents of strengths i, j respectively. Let us take the line joining the centres of these currents as the axis of x; let the plane of ds_1 and x be taken as the plane of xy; let θ_1, θ_2 be the angles which ds_1, ds_2 respectively make with the axis of x, η the angle which the plane through ds_2 and r makes with the plane of xy.

By Ampère's second proposition the action of ds_1 on ds_2 will be the sum of the action of

$$\begin{cases} ds_1 \cos\theta_1 \text{ or } \alpha_1 \text{ along } x \\ ds_1 \sin\theta_1 \text{ or } \beta_1 \text{ along } y \end{cases}$$

on

$$\begin{cases} ds_2 \cos\theta_2 \text{ or } \alpha_2 \text{ along } x \\ ds_2 \sin\theta_2 \cos\eta \text{ or } \beta_2 \text{ along } y \\ ds_2 \sin\theta_2 \sin\eta \text{ or } \gamma_2 \text{ along } z. \end{cases}$$

Now by proposition I. α_1 cannot exert a force on either β_2 or γ_2, because it is in planes which bisect β_2 and γ_2 at right angles, so that the only component on which α_1 can exert a force is α_2. Let the force between these components be

$$\frac{a}{r^2}\alpha_1\alpha_2.$$

where r is the distance between the centres of the elementary currents.

In the same way we can show that the only component on which β_1 can exert any force is β_2. Let the force between these two elements be

$$\frac{b}{r^2}\beta_1\beta_2.$$

Thus the force between the two elements ds_1, ds_2 is

$$\frac{1}{r^2}\{a\alpha_1\alpha_2 + b\beta_1\beta_2\},$$

or, substituting for $\alpha_1\alpha_2$, $\beta_1\beta_2$ their values:

$$\frac{1}{r^2}\{a\cos\theta_1\cos\theta_2 + b\sin\theta_1\sin\theta_2\cos\eta\}\, ij\, ds_1\, ds_2.$$

The proposition III., that the action of a closed circuit on an element of current is always at right angles to the element, leads on integration to the condition

$$2a + b = 0,$$

so that the force between the two elements equals

$$\frac{a}{r^2}\{\cos\theta_1\cos\theta_2 - 2\sin\theta_1\sin\theta_2\cos\eta\}\, ij\, ds_1\, ds_2.$$

From this we are able to find the force between any two circuits or parts of circuits. To find the force on a magnetic system, Ampère used his

principle that the magnetic action of an electric current was the same as that due to a magnetic shell bounded by the circuit and magnetised to the proper intensity. In this way Ampère gave a complete theory of the action of currents upon currents and upon magnets—in fact, a complete theory of all the effects produced by a current which were known when his paper was published.

It is difficult to overrate the service which Ampère's theory has rendered to the science of electrodynamics. Perhaps the best evidence of its value for practical purposes is the extreme difficulty of finding any experiment which proves that it is insufficient. In spite of this, however, as a dynamical theory it is very unsatisfactory. If, as we are led to do by Ampère, we attach physical importance to elements of current, and regard them as something more than mathematical helps for calculating the force between two closed circuits, then we are driven to ask, not only what is the law of force between the elements, but what is the energy possessed by a system consisting of two such elements. If we do this, and find this energy by calculating the amount of work required to pull the elements an infinite distance apart, we arrive at the conclusion that the energy must depend upon the angles which the elements make with each other and with the line joining them; but if this is so, then the force between the elements cannot be along the line joining them, and there must in addition to this force be couples acting on the elements. For these reasons we see that Ampère's theory cannot give the complete action between two elements of current. What it does—and this for practical purposes is an advantage and not a disadvantage—is to give in most cases, instead of the complete action between two elements, that part of it which really affects the case under consideration.

Before discussing cases, however, in which the terms which Ampère neglects might be expected to produce measurable effects, we shall, in order to compare the various theories more easily, proceed to consider other theories of the same class.

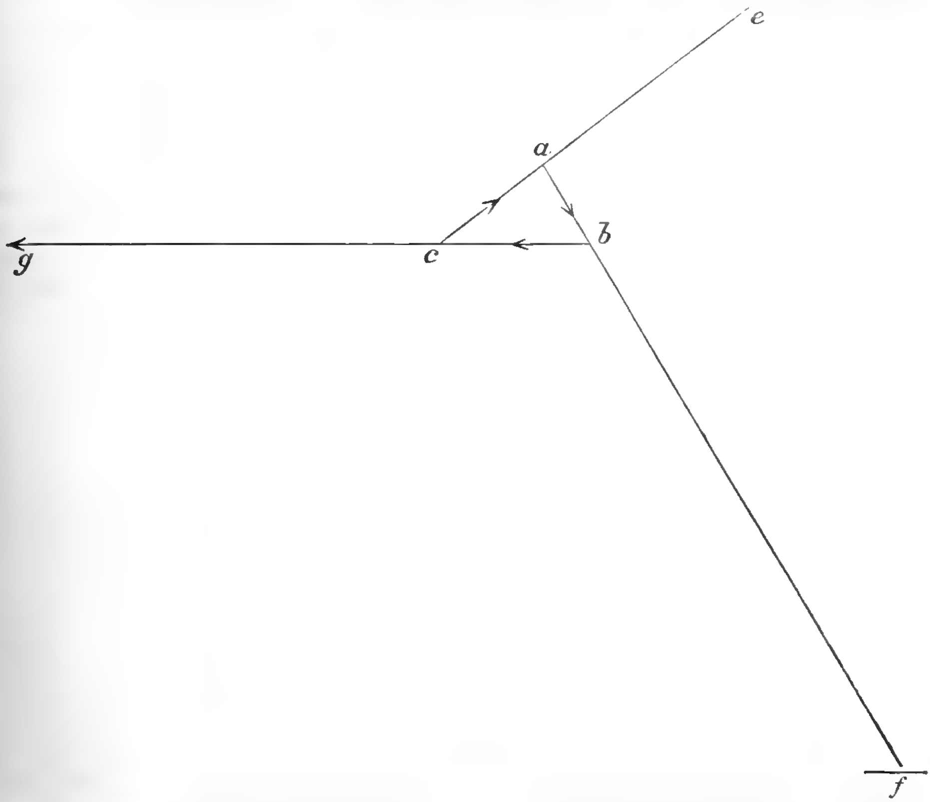
Grassmann's Theory.[1]

The method by which Grassmann obtains his theory is very remarkable. He objects to Ampère's formula for the force between two elements of current, because it makes the force between two parallel elements change from an attraction to a repulsion when the angle which the elements make with the line joining them passes through the value $\cos^{-1} 2/3$, and the object of his investigation is to get a law of force free from this peculiarity, and which, while giving the same result as Ampère's for closed circuits, shall yet be as simple as possible. He begins by regarding any circuit as built up of 'Winkelströme,' *i.e.*, currents flowing along the two infinite lines which form any angle. He points out that a circuit of any shape can be built up of such currents; the circuit *abc*, for example, may be regarded as built up of the 'Winkelströme' *eaf*, *fbg*, and *gce*.

Grassmann proceeds to calculate by Ampère's formula the action of a 'Winkelstrom' upon an element of current (a). Since the 'Winkelstrom' will have no action upon an element of current perpendicular to its plane, we see that it is only necessary to calculate its action upon the component (a') of a in its own plane. Grassmann does this by calculating the effect due to each arm of the 'Winkelstrom' separately. He

[1] Pogg. *Ann.* 64, p 1, 1845; Crelle, 83, p. 57

finds expression for the forces along and perpendicular to a', due to an infinite rectilinear current starting from a definite point. The force of such a current along a' does not depend on the angle the current makes with the line from its end to a', so that the effects of two such currents starting from the same point and flowing in opposite directions, *i.e.* of a 'Winkelstrom,' will be to produce no force along a'; thus the effect of a 'Winkelstrom' on an element of current in its own plane will be a force at right angles to the element. The force at right angles to a' due to a rectilinear current will consist of two parts, one independent of the angle made by the current with the line joining its end to the element, the other depending upon this angle. The first part will vanish when we consider a 'Winkelstrom'; the second part only will produce any effect.



Now Grassmann says that it will much simplify the analysis, and obviously (since any closed circuit may be built up of 'Winkelströme') lead, for closed circuits, to the same result as Ampère's formula, if we suppose that the law of force between elements of currents is such that the only effects produced by a rectilinear current are those which do not vanish for a 'Winkelstrom,' and hence that a straight current exerts on an element of current a force at right angles to the projection of the element on the plane containing the centre of the element and the rectilinear current, and that the magnitude of this force is

$$\frac{ij\,ds'}{r}\cot\frac{a}{2},$$

where i is the strength of the rectilinear current, j the strength of the

element of current, ds' its projection on the plane through its centre containing the straight current, r the distance of the element from the end of the straight current, and a the angle which the rectilinear current makes with the line joining its extremity to the elementary current. By taking the difference of two such rectilinear currents, Grassmann finds the action of an element (β) of current on another element (α) is a force at right angles to α', the component of α in the plane containing β and the middle point of α and equal to

$$i\,j\,\frac{d\sigma ds'}{r^2}\sin\theta,$$

where θ is the angle which β makes with r, $d\sigma$ the length of (β), and j the current flowing through it.

The direction of the force is along AB, where A is the centre of the element (α) and B the point where the normal to α' is cut by β produced *in the direction* of the current.

If we treat this theory in the same way as we did Ampère's on p. 99 by considering the action of the component α_1, β_1 of an element of current ds_1 on the components α_2, β_2, γ_2 of another element ds_2, we see that Grassmann's theory is equivalent to supposing that α_1 exerts no force on α_2, β_2, or γ_2; that β_1 exerts a force $A\beta_1\alpha_2$ on α_2 at right angles to α_2 in the plane of xy, and a force $A\beta_1\beta_2$ on β_2 at right angles to it, that is, along the line joining the element, and that it exerts no force on γ_2.

Thus we see that Grassmann's theory is equivalent to replacing Ampère's assumption, that the force between two elements of current acts along the line joining them, by the assumption that two elements of current in the same straight line exert no force on each other.

As a dynamical theory of electrodynamics, Grassmann's theory is open to the same objection as Ampère's, that it does not take into account the couples which may exist between the elements, and also to the additional objection that, according to it, the action of an element of current ds_1 on another element ds_2 is not equal and opposite to the action of ds_2 on ds_1, so that the momentum of the two elements ds_1 and ds_2 will not remain constant, and, as the theory does not take into account the surrounding ether, there is no way of explaining what has become of the momentum lost or gained by the elements. As a piece of geometrical analysis, however, the theory is very elegant and worthy of the author of the 'Ausdehnungslehre.'

From the way in which Grassmann's theory was developed we see that between closed circuits it must give the same forces as Ampère's; for unclosed circuits this is not the case, and Grassmann, at the end of the paper quoted above, mentions a case where the two theories would give opposite results, assuming that unclosed streams exist. Suppose we have a magnet ns and an unclosed current AB in the same plane as the magnet and passing through its middle point, then if Ampère's theory be true, the magnet will twist in one direction; if Grassmann's, it will twist in the opposite. This depends upon the change, according to Ampère's theory, of the force between two parallel elements from attraction to repulsion, when they make the angle with the line joining them at less than $\sin^{-1} 1/\sqrt{3}$, while according to Grassmann's theory, there is no such change.

Stefan's Theory.[1]

This resembles Ampère's theory very closely, except that Stefan does not make the assumption that the force between two elements of current is along the line joining them: this difference leads to the introduction of two forces which Ampère neglects.

We shall use the same notation as when we discussed Ampère's theory, and consider, as before, the action of an element of current ds_1 on another element ds_2. Stefan, like Ampère, assumes that we may replace an element of current by its component, so that we have to consider the action of the components (α_1, β_1) of ds_1 on the components $(\alpha_2, \beta_2, \gamma_2)$ of ds_1.

As in Ampère's theory, the component α_1 is supposed to exert a force

$$\frac{a\alpha_1\alpha_2}{r^2}$$

on α_2, this force by symmetry must be along the line joining the elements.

α_1 is supposed to exert a force on β_2 equal to

$$\frac{c\alpha_1\beta_2}{r^2}$$

along the axis of y. We can see that this force may exist, for it is conceivable that it should be in the same direction as β_2 when α_1 points from the middle of ds_1 to the middle of ds_2, and in the opposite direction to β_2 when α_1 points in the opposite direction. Stefan assumes that α_1 exerts no force on β_2 parallel to the axis of z, and no force at all on γ_2.

β_1 is supposed to exert a force on α_2 parallel to the axis of y and equal to

$$\frac{d}{r^2}\beta_1\alpha_2.$$

We may see, by the same reasoning as we used before for the force between β_1 and α_2, that it is conceivable that this force may exist. β_1 is supposed to exert no force on α_2 parallel to the axis of z.

As in Ampère's theory, β_1 is supposed to exert a force on β_2 equal to

$$\frac{b}{r^2}\beta_1\beta_2,$$

this force must by symmetry be along the line joining the elements; β_1 is supposed to exert no force on γ_2.

Thus the action of ds_1 on ds_2 consists of a force

$$\frac{1}{r^2}\left\{a\alpha_1\alpha_2 + b\beta_1\beta_2\right\}$$

along the line joining the elements, and a force

$$\frac{1}{r^2}\left\{c\alpha_1\beta_2 + d\beta_1\alpha_2\right\}$$

at right angles to this line in the plane containing ds_1 and r. If we take

[1] Stefan, *Wien. Sitzungsberichte*, 59, p. 693, 1869.

arbitrary coordinate axes and suppose that x, y, z are the coordinates of ds_1, x^1, y^1, z^1 those of ds_2, then the x component of the force on ds_2 due to ds_1 is shown by Stefan to be equal to

$$i\,j\,ds_1\,ds_2\left\{m\,\frac{d_2}{ds_1 ds_2}\,\frac{(x^1-x)}{r}+n\,\frac{d}{ds_1}\,\frac{1}{r}\,\frac{dx^1}{ds_2}+p\,\frac{d}{ds_2}\,\frac{1}{r}\,\frac{dx}{ds_1}+q\,\frac{x^1-x}{r^3}\cos\epsilon\right\}$$

with similar expressions for the force parallel to the axes of y and z.

Here i, j are the currents through ds_1, ds_2 respectively, ϵ is the angle between the elements of current, and

$$\begin{aligned} m&=-\tfrac{1}{3}\{a-b-c-d\}\\ n&=\tfrac{1}{3}\{a-b-c+2d\}\\ p&=-\tfrac{1}{3}\{a-b+2c-d\}\\ q&=\tfrac{1}{3}\{a+2b-c-d\}. \end{aligned}$$

We see from this expression for the force parallel to x that the last term is the only one which does not vanish when integrated round two closed circuits of which ds_1 and ds_2 are elements. So that the force will depend only upon q; the value of q will depend upon the units we adopt: in Stefan's work q is put equal to $-1/2$.

This is the only condition to be got by considering the translatory force between two circuits; we can get another by considering the couple acting on the closed circuit, supposed rigid, of which ds_2 forms a part. For the z component N of this couple Stefan finds the expression

$$\mathrm{N}=i\,j\,q\iint\frac{y^1x-x^1y}{r^3}\cos\epsilon\,ds_1ds_2-i\,j\,p\iint\frac{1}{r}\left\{\frac{dx^1}{ds_2}\,\frac{dy}{ds_1}-\frac{dy^1}{ds_2}\,\frac{dx}{ds_1}\right\}ds_1ds_2.$$

But supposing the two circuits to have a potential

$$i\,j\iint\frac{\cos\epsilon}{r}\,ds_1\,ds_2,$$

we can easily see that the couple

$$=i\,j\iint\frac{y^1x-x^1y}{r^3}\cos\epsilon\,ds_1ds_2-i\,j\iint\frac{1}{r}\left\{\frac{dx^1}{ds_2}\,\frac{dy}{ds_1}-\frac{dy^1}{ds_2}\,\frac{dx}{ds_1}\right\}ds_1ds_2;$$

thus if two circuits have a potential

$$p=q,$$

or substituting for p and q their values,

$$2a+b+c-2d=0.$$

If $c=0$ and $d=0$, as in Ampère's theory, this relation becomes

$$2a+b=0,$$

which is the same relation as Ampère deduced by finding the condition that the force due to a closed circuit on an element of current should be at right angles to the element, and Stefan has proved that on his theory the same condition leads to the equation

$$p=q,$$

i.e., the same condition as the one which expresses that two closed circuits have a potential.

Stefan shows that, from the consideration of the action of closed circuits on elements of other circuits or of themselves, it is impossible to get any other relation between the quantities a, b, c, d, so that we have only two relations between the quantities a, b, c, d, and thus two of them must be indeterminate.

We may give any values we please to these quantities, provided they satisfy these two relations; if we put $c = 0$, $d = 0$ we get Ampère's theory; if $a = 0$, $c = 0$, Grassmann's; and we can get a number of other theories by giving different values to these quantities.

Stefan's theory is open to the same objection as Ampère's, since it does not take into account the couples which one element may produce on another. He also limits the generality of his theory by supposing that the force between two elements of currents in one plane is in that plane.

Korteweg's Theory.[1]

According to this theory, the forces between two elements of current are the same as in Stefan's theory; Korteweg, however, considers in addition the couples which one element may produce on another.

If we use the notation we adopted in discussing Stefan's theory, we have, considering the force on ds_2, a force

$$\frac{1}{r^2}\{a\alpha_1\alpha_2 + b\beta_1\beta_2\}$$

along the line joining the elements, and a force

$$\frac{1}{r^2}\{c\alpha_1\beta_2 + d\alpha_2\beta_1\}$$

parallel to the axis of y.

In addition to these forces, Korteweg supposes that from the action of α_1 on β_2 there is a couple whose axis is parallel to the axis of z equal to

$$f\alpha_1\beta_2,$$

and from the action of α_1 on γ_2 a couple on γ_2 whose axis is parallel to the axis of y and equal to

$$-f\alpha_1\gamma_2;$$

from the action of β_1 on α_2 there is a couple on α_2 whose axis is parallel to the axis of z and equal to

$$g\beta_1\alpha_2,$$

and from the action of β_1 on γ_2 there is a couple on γ_2 whose axis is parallel to the line joining the elements and equal to

$$h\beta_1\alpha_2.$$

If we now take arbitrary co-ordinate axes, the forces on the element ds_2 are the same as those given by Stefan's theory. The couples, however, are different. The component parallel to the axis of x of the couple on ds_2 is given by the equation

$$\mathrm{L} = \left[\frac{d}{r^2}\,\frac{dr}{ds_2}\left(y\frac{dz}{ds_1} - z\frac{dy}{ds_1}\right) - \frac{a-d-c}{r^3}\,\frac{dr}{ds_2}\,\frac{dr}{ds}\,(y^1z - z^1y)\right.$$

[1] Crelle, xc. p. 49, 1881.

$$- \frac{b}{r^2} \frac{d^2r}{ds_1 ds_2} (y^1z - z^1y) - \frac{c}{r^2} \frac{dr}{ds_1} \left(z \frac{dy^1}{ds_2} - y \frac{dz_1}{ds_2} \right)$$

$$+ \frac{(h+g)}{r} \frac{dr}{ds_1} \left\{ (y^1 - y) \frac{dz_1}{ds_2} - (z^1 - z) \frac{dy^1}{ds_2} \right\}$$

$$+ \frac{h-f}{r} \frac{dr}{ds_2} \left\{ (y^1 - y) \frac{dz}{ds_1} - (z^1 - z) \frac{dy}{ds_1} \right\}$$

$$- h \left\{ \frac{dy^1}{ds_2} \frac{dz}{ds_1} - \frac{dy}{ds_1} \frac{dz}{ds_2} \right\} \Bigg] ii\, ds_1\, ds_2,$$

with similar expressions for the components of couple around the axes of y and z.

By making the force between two closed circuits have the same value as that given by Ampère's theory, Korteweg finds that

$$a + 2b - d - c = -3A^2,$$

where A is a constant quantity whose value depends upon the unit of current adopted.

By making the couples produced by one closed circuit on another have the same value as that given by Ampère and the potential theory, he finds that

$$\frac{d}{dr}(r^2h) + (g-h)r - c + 2A^2 = 0.$$

Korteweg considers that the experiments of v. Ettingshausen, quoted above, prove (1) that the force on an element of circuit produced by a closed circuit is at right angles to the element, and (2) that the couple on an element due to a closed circuit has the value given by Ampère's theory. The first condition gives

$$c - b = 2A^2;$$

the second the two conditions

$$\frac{d}{dr}(rh) - f = 0$$

$$h + g = 0.$$

And he points out that we cannot get any more conditions by considering the action between two closed circuits, or the action of a closed circuit on an element of another.

It should be noticed that since, according to this theory, part of the action of one element of a circuit on another consists of a couple, the condition that the force due to a closed circuit on an element of another should be at right angles to the element is not, as in Stefan's theory, identical with the condition that the expression for the couple exerted by one closed circuit on another should be the same as that given by Ampère.

This theory is valuable because it is the most general one of the class we are considering which has been published. It is the only one which takes into account the couples, and by giving special values to the quantities a, b, c, d, f, g, h, we can get any of the other theories of this class.

On the theories which explain the action of currents by assuming that the forces between two electrified bodies depend upon the velocities and accelerations of the bodies.

According to these theories a body conveying an electric current contains equal quantities of positive and negative electricity, so that it will not exert any ordinary electrostatic effect: the positive electricity is supposed, however, to be moving differently from the negative. In some of the theories (Weber's, Gauss's, Riemann's) Fechner's hypothesis, that the electric current consists of positive electricity moving in one direction (the direction of the current), and an equal quantity of negative electricity moving at the same speed in the opposite direction, is assumed; in other theories (Clausius') only one of the electricities is supposed to move, the other remains at rest. We can see in a general way how the assumption that the forces between two electrified particles depend on the velocities and the accelerations of the particles can explain the effects produced by an electric current.

Let us take first the mechanical action between two circuits A and B, and let us consider the action of an element (a) of A on an element (b) of B. We shall consider first the action of the two electricities which are flowing through a on the positive electricity which is flowing through b. Since the motion of the positive electricity in a relative to that of the positive electricity in b is not the same as the motion of the negative electricity in a relative to that of the positive in b, the forces due to the positive and negative electricities in a will not counterbalance, so that there will be a resultant force on the positive electricity in b depending on the inequality between the motion of the positive and negative electricities in a relative to that of the positive in b. Similarly there will be a force on the negative electricity in b depending on the inequality between the velocities of the positive and negative electricities in a relative to that of the negative in b, and, except for special laws of force and special values of the velocities of the electricities in b, this force will not be equal and opposite to the force on the positive electricity in b, so that a mechanical force on b will be produced by the currents through a.

Let us now consider how inductive forces can be explained by this hypothesis: let us suppose that the element a is moving, and that the element b is at rest. The velocity of the electricity in a will be the resultant of the velocity with which the electricity flows through a and the velocity of translation of a itself, so that since the velocities of flow of the positive and negative electricities are different, the actual velocity of the positive electricity will differ in magnitude from the velocity of the negative (unless, assuming Fechner's hypothesis, the element a is moving at right angles to itself); thus the force due to the positive electricity in a on a unit of positive electricity at b will not be equal and opposite to that due to the negative electricity in a, and thus there will be an E.M.F. at b due to the motion of a. This explains induction due to the motion of the primary circuit.

Let us now consider induction due to the variation of the intensity of the current in the primary circuit. According to all the theories there is a force produced by a moving electrified body proportional to the first power of the acceleration of that body. Let us consider the elements a and b again, and suppose that a variable current is flowing through a and no current through b; then if we suppose that a variation in the intensity

of a current is accompanied by an alteration in the velocity of flow, the acceleration of the positive electricity will, if we take Fechner's hypothesis, be equal and opposite to that of the negative; but since there is a part of the force due to the moving electrified body which changes sign both with the electrification and the acceleration, the force due to the acceleration of the positive electricity will be equal in all respects to that due to the acceleration of the negative, so that there will be a resultant force on a unit of positive electricity at b, and this force is the electromotive intensity at b due to the alteration of the intensity of the current in a. In this way we can explain the induction due to the variation of the current in the primary circuit.

Theories of this kind have been given by Gauss, Weber, Riemann, and Clausius, and these writers have given expressions for the force between two electrified particles moving in any way. We shall afterwards consider these expressions in detail, but we may remark in passing that the theories of Gauss, Weber, and Riemann have much in common; among other things they all lead to impossible results. In addition Clausius has shown that, unless we make Fechner's hypothesis about a current, viz. that it consists of equal quantities of positive and negative electricity moving with equal speeds in opposite directions, a current would on these theories exert a force on an electrified body at rest.

The question of the forces due to moving electrified bodies is interesting in connection with electrolysis. Taking the ordinary view that the current is carried by the ions, we know from Hittorf's researches that the anion and the cation move at different rates, so that the forces produced by these will be different; hence we should expect an electrolyte conveying a current to exert a force on a charged particle at rest.

We shall now go on to consider the various theories separately.

Gauss's Theory.[1]

Gauss assumes that the force between two particles separated by a distance r and charged with quantities of electricity e and e' is along the line joining the particles and equal to

$$\frac{ee'}{r^2}\left\{1+\frac{1}{c^2}\left\{u^2-\frac{3}{2}\left(\frac{dr}{dt}\right)^2\right\}\right\}$$

where u is the relative velocity of the two particles and c is a constant. This law will, if we make Fechner's hypothesis, explain the mechanical force between two circuits; but, since it contains no term depending on the acceleration, it cannot explain the E.M.F. produced by the variation of the strength of the current in the primary; it is also inconsistent with the principle of the Conservation of Energy, and so we need not consider it any further.

W. E. Weber's Theory.[2]

Weber assumes that the force between two charged particles, using the same notation as before, is

$$\frac{ee'}{r^2}\left\{1+\frac{1}{c^2}\left(r\frac{d^2r}{dt^2}-\tfrac{1}{2}\left(\frac{dr}{dt}\right)^2\right)\right\}$$

[1] Gauss's theory was published after his death in his collected works, Göttingen edition, vol. v. p. 616. See also Maxwell's *Electricity and Magnetism*, 2nd edit. vol. ii. p. 440.

[2] Weber's theory was published in 1846 in *Abhandlungen der Königlich-Säch-*

This formula is not inconsistent with the principle of the Conservation of Energy; making Fechner's hypothesis, it will explain the mechanical force between circuits conveying currents; it will also explain induction due both to the motion of the primary and the alteration in the strength of the current in the primary. We shall see, however, that it makes a body under certain circumstances behave as if its mass were negative; *i.e.* if it were acted on by a force in a direction opposite to that in which it is moving, its velocity would continually increase.

Riemann's Theory.

This is explained in his 'Schwere Electricität und Magnetismus,' edited by Hallendorff, p. 327. According to this theory the force between two electrified bodies is not altogether along the line joining them, but consists of the following parts:—

1. A force along the line joining the particles equal with the same notation as before to

$$\frac{ee'}{r^2}\left\{1+\frac{u^2}{c^2}\right\}$$

2. A force on the first particle parallel to its velocity relative to the second equal to

$$-\frac{2ee'}{c^2r^2}u\frac{dr}{dt}.$$

3. A force on the first particle parallel to its acceleration relative to the second equal to

$$\frac{2ee'}{c^2r}f,$$

where f is the relative acceleration of the particles.

There are of course similar forces acting on the second particles, and we see from the form of the expressions of the forces that the force on the first particle is equal and opposite to the force on the second. Riemann's law of force is not inconsistent with the principle of the conservation of energy, and it explains the mechanical force between two circuits; hence it must explain the induction of currents. We shall see, however, that it is open to the same objection as Weber's theory, viz. that it makes an electrified particle under certain circumstances behave as if its mass were negative.

Clausius' Theory.[1]

If x, y, z are the co-ordinates of the first electrified particle, x', y', z' those of the second, then according to this theory the x component of the force on the first particle is equal to

$$-ee'\left[\frac{d}{dx}\left\{(1-v\,v'\cos\epsilon/c^2)\frac{1}{r}\right\}-\frac{1}{c^2}\frac{d}{dt}\left(\frac{1}{r}\;\frac{dx'}{dt}\right)\right]$$

With similar expressions for the components parallel to y and z, here

sischen Gesellschaft der Wissenschaften, 1846, p. 211; it is reprinted in *Electrodynamische Maassbestimmungen*, 1871. A good account of the theory is given in Maxwell's *Electricity and Magnetism*, 2nd edit. vol. ii. chap. xxiii.

[1] This theory is given in Crelle, vol. 82, p. 85. There is also a full abstract in Wiedemann's *Beiblätter*, vol. i. p. 143.

v and v' are the velocities of the first and second particles respectively, and ϵ is the angle between their directions of motion. We may analyse these forces a little differently, and say that the force on the first particle consists of—

1. A force along the line joining the particles equal to

$$\frac{ee'}{r^2}\left\{1-vv'\cos\epsilon/c^2\right\}$$

2. A force parallel to the velocity of the *second* particle and equal to

$$\frac{ee'}{c^2r^2}\frac{dr}{dt}v'.$$

3. A force parallel to the acceleration of the *second* particle equal to

$$-\frac{ee'}{c^2r}\frac{dv'}{dt}.$$

We have, of course, corresponding expressions for the force on the second particle.

Clausius' formulæ differ from those of Gauss, Weber, and Riemann in two very important respects.

1. They make the forces between two electrified bodies depend on the absolute velocities and accelerations of the bodies, while the others make them depend only on the relative velocities and accelerations.

2. They do not make the forces between the bodies equal and opposite, so that the momentum of the system does not remain constant.

These results show that if this theory is true, we must take the ether surrounding the bodies into account. The first result can then be explained by supposing that the velocities which enter into the formulæ are the velocities of the bodies relatively to the ether at a considerable distance from the bodies, and the second result by supposing that the ether possesses a finite density, and that the momentum lost or gained by the bodies is added to or taken from the surrounding ether.

The case is analogous to the case of two spheres A and B moving in an incompressible fluid; in this case the forces on the sphere A depend on the velocities and accelerations of B relatively to the fluid at a great distance from the sphere, and are independent of the velocity and acceleration of A; the forces are not equal and opposite, and the momentum lost or gained by the system is added to or taken from the momentum of the fluid. At the end of this section we shall see that, if we assume that variations in what Maxwell calls the electric displacement produce effects analogous to those produced by ordinary conduction currents, we get the same forces between moving electrified bodies as are given by Clausius' theory.

Clausius' theory is not inconsistent with the principle of the conservation of energy, and we shall see that it does not lead to the same difficulty as the theories of Weber and Riemann, viz., that under special circumstances a body would behave as if its mass were negative.

Assuming that in an electric current we have equal quantities of positive and negative electricity moving with different velocities, Clausius has shown in the paper already cited that his theory gives Ampère's results for the mechanical force between two circuits, and the usual

expression for the induction due to the motion of the primary circuit, or variation in the strength of the current passing through it.

Fröhlich[1] urges against Clausius' law that since, according to it, an electric current in motion exerts an electromotive force on a moving electrified particle, even though the particle is moving at the same rate as the circuit, every current on the earth's surface ought to exert an electromotive force on an electrified particle relatively at rest, since each is moving with the velocity of the earth. This force is one that can be derived from a potential, so that the integral of the force taken round a closed curve would vanish, and thus, even if this result were true, two circuits would not induce currents in each other if they were relatively at rest. Budde[2] points out, however, that the moving circuit would exert an electromotive force at each point of itself, and thus cause a separation of the electricity in the circuit, so that it would get coated with a distribution of electricity, the electrostatic action of which would balance that due to the action due to its motion on a point relatively at rest. The velocities which enter into Clausius' formulæ are velocities relative to the ether, so that if the ether moves with the earth, an electric current will, according even to this theory, exert no electromotive force on a point relatively at rest, and there will be no electrification on the surface of the circuit. The velocity c which occurs in all these theories is a velocity comparable with the velocity of light.

General Considerations on these Theories.[3]

We shall now go on to discuss a general way of treating theories of the kind we have been considering. Perhaps the best way of doing this is to consider not the forces between the electrified bodies, but the energy possessed by them. If the energy depends on the electrification there will be forces between two electrified bodies. Now the potential energy depends on the electrification, and this dependence produces the ordinary electrostatic forces between two electrified bodies at rest. If, however, the kinetic energy as well as the potential depends on the electrification, then the forces between two electrified bodies in motion will be different from the forces between the same bodies at rest. An easy way of seeing this is by means of Lagrange's equations.

If T be the kinetic energy, and x a co-ordinate of any kind, then we have, by Lagrange's equations,

$$\frac{d}{dt}\frac{d\mathrm{T}}{d\dot{x}}-\frac{d\mathrm{T}}{dx}=\text{external force of type } x.$$

Hence if we have any term T′ in the expression for the kinetic energy, we may, if we like, regard it as producing a force equal to

$$-\frac{d}{dt}\frac{d\mathrm{T}'}{d\dot{x}}+\frac{d\mathrm{T}'}{dx}.$$

A simple illustration of this is afforded by the centrifugal force. In

[1] Fröhlich, *Wied. Ann.*, ix. p. 277, 1880.

[2] *Wied. Ann.*, x. p. 553, 1880.

[3] See Clausius 'On the Employment of the Electrodynamic Potential for the Determination of the Ponderomotive and Electromotive Forces,' *Phil. Mag.*, 1880, v. 10, p. 255.

the expression for the kinetic energy of a moving particle there is the term

$$\tfrac{1}{2}mr^2\,\dot{\theta}^2,$$

where r is the distance of the particle from some fixed point, and θ the angle which the radius from this point to the particle makes with some fixed line; m is the mass of the particle. This term, by the above rule, will give rise to a force of type r, *i.e.*, along the radius vector equal to

$$mr\dot{\theta}^2,$$

and this is the ordinary centrifugal force.

Now let us consider a moving electrified body. If it is symmetrical, and moves in an isotropic dielectric, it is evident that the electrification, if it enters at all, can only enter as a factor of the total velocity q, and cannot affect the separate components of the velocity differently.

Let us suppose that the body is charged with a quantity of electricity denoted by e, then the kinetic energy, if it depends on the electrification, must be of the form

$$\tfrac{1}{2}mq^2 + f(e)q^2,$$

where $f(e)$ denotes some function of e. Now $f(e)$ must be always positive, for if it were negative we could make

$$\tfrac{1}{2}m + f(e)$$

negative, and then the electrified body would behave like one of negative mass. The simplest form satisfying this condition which we can take for $f(e)$ is αe^2, where α is some positive constant; so that the form of expression for the kinetic energy may be taken as

$$(\tfrac{1}{2}m + \alpha e^2)q^2.$$

Now let us go on to the case where we have two electrified bodies present, with charges e and e' of electricity; let m and m' be their masses, q, q' their velocities, of which the components parallel to the axes of x, y, z are (u, v, w), (u', v', w') respectively, the co-ordinates of the particles being (x, y, z), (x', y', z').

If everything is symmetrical, the expression for the kinetic energy, if it only involves second powers of the charges of electricity, will be of the form

$$\tfrac{1}{2}mq^2 + \tfrac{1}{2}mq'^2 + \alpha e^2q^2 + \beta e'^2\,q'^2 + ee'\,\kappa\,.\,f\,\{u, v, w, u', v', w'\}$$

where $f\,(u, v, w, u', v', w')$ is a quadratic function of u, v, w, u', v', w'.

By Lagrange's equations we see that the last term will give rise to a force parallel to the axis of x on the particle whose charge is e equal to

$$\kappa ee'\left\{\frac{df}{dx} - \frac{d}{dt}\frac{df}{du}\right\},$$

with similar expressions for the forces parallel to y and z. We can see, by substituting in this expression, that we get Weber's law if we make

$$f = \frac{1}{r}\left\{\frac{x - x'}{r}(u - u') + \frac{y - y'}{r}(v - v') + \frac{z - z'}{r}(w - w')\right\}^2;$$

Riemann's law, if we make

$$f=\frac{1}{r}\{(u-u')^2+(v-v')^2+(w-w')^2\};$$

Clausius' law, if we make

$$f=\frac{1}{r}\{uu'+vv'+ww'\};$$

and that we cannot get Gauss's law in this way; this is in accordance with the fact that Gauss's law does not satisfy the principle of the conservation of energy. This way of considering the theories enables us to see that neither Weber's nor Riemann's formulæ can be right, for if they were, an electrified body, when in presence of another, would, under certain circumstances, behave as if its mass were negative. Thus take Weber's law as an example: let us suppose that two electrified bodies are moving along the line joining them, which we may take as the axis of x; then the expression for the kinetic energy, putting in the value of f which corresponds to Weber's law, is

$$\tfrac{1}{2}mq^2+\tfrac{1}{2}mq'^2+\alpha e^2q^2+\beta e'^2q'^2+\frac{\kappa ee'}{r}\{q-q'\}^2,$$

so that if

$$\tfrac{1}{2}m+\alpha e^2+\frac{\kappa ee'}{r}$$

be negative, then the coefficient of q^2 in the kinetic energy will be negative, and the body will behave as if its mass were negative; and, by sufficiently increasing e' or diminishing r, we can make this expression negative, so that Weber's law leads to results which are inconsistent with experience. This result of Weber's law was first pointed out by Helmholtz.[1]

Exactly the same objection applies to Riemann's theory, and indeed we see that it will apply to any theory which makes the force between two electrified bodies depend on *relative* velocities and accelerations.

The same objection need not apply to Clausius' theory, for substituting the value of f belonging to his theory, the kinetic energy equals

$$(\tfrac{1}{2}m+\alpha e^2)q^2+(\tfrac{1}{2}m'+\beta e'^2)q'^2+\kappa ee'\,\frac{qq'\cos\epsilon}{r},$$

so that the kinetic energy will be always positive if

$$(\tfrac{1}{2}m+\alpha e')\ \ (\tfrac{1}{2}m'+\beta e'^2)>\frac{\kappa^2e^2e'^2\cos^2\epsilon}{4r^2}.$$

This condition will evidently be satisfied if

$$\alpha\beta>\frac{\kappa^2}{4r^2},$$

and this relation does not involve the electrification. We cannot assume that we can make r so small that this condition is not satisfied, for r has a minimum value depending upon the shape and size of the electrified bodies. For example, if these are spheres, r cannot be less than the sum of their radii. On the other hand, α and β may be functions of the

[1] *Ueber die Theorie der Elektrodynamik.* Crelle, vol. lxxv. p. 535; Collected Works, Bd. 1, S. 647.

sizes of the electrified bodies, and the geometrical relations may be such that the condition written above must be always satisfied.

Physical reasons why the force between two electrified bodies should depend on their velocities and accelerations.

If we assume Maxwell's hypothesis that a change in the electric polarisation produces the same effect as an electric current, then we see that the kinetic energy of an electrified body must be different from the kinetic energy of the same body moving at the same rate but not electrified. For let us suppose that we have an electrified body at rest, and consider the amount of work necessary to start it with a velocity q. It is evident that it will be greater than when it is not electrified, for when it is electrified and in motion the electric polarisation in the surrounding dielectric will be in changing, and so in addition to starting the body with a velocity q we have, if Maxwell's hypothesis be true, to establish what is equivalent to a field full of electric currents. The production of these currents of course requires work, so that more work is required to start the body with a velocity q when it is electrified than when it is not; in other words, the kinetic energy of a moving electrified body is greater than that of one not electrified, but under similar conditions as to mass and velocity. In fact in this case electricity behaves as if it possessed inertia.

In a paper published in the 'Philosophical Magazine,' April 1881, I have shown that the kinetic energy of a charged sphere of radius a and mass m moving at a velocity q

$$= \tfrac{1}{2}mq^2 + \tfrac{2}{15}\frac{e^2\mu}{a}q^2,$$

where μ is the magnetic permeability of the surrounding dielectric and e the charge on the sphere. If there are two spheres in the field, then I have shown in the same paper that the kinetic energy

$$= \tfrac{1}{2}mq^2 + \tfrac{2}{15}\frac{\mu e^2}{a}q'^2 + \tfrac{1}{2}m'q'^2 + \tfrac{2}{15}\frac{\mu e'^2}{a'}q'^2 + \tfrac{1}{3}\frac{\mu ee'}{\mathrm{R}}qq'\cos\epsilon,$$

where corresponding quantities for the two spheres are denoted by plain and accented letters. We see from this expression that the forces between the spheres are exactly the same as those given by Clausius' formulæ. It would not, however, be legitimate to go and develope the laws of electrodynamics from this result in the way that Clausius does, as Clausius' conception of an electric current does not accord with that of the displacement theory. We may remark that in this case the part of the kinetic energy due to the electrification is always positive.

On theories which are based on dynamical considerations, but which neglect the action of the dielectric.

F. E. Neumann[1] was the first to develope a theory founded on the principles of the Conservation of Energy. His theory was based upon the assumption that two elements of circuit ds, ds', traversed by currents ι, ι' possess an amount of energy equal to

$$\mathrm{A}^2\frac{\iota\,\iota'\cos\epsilon}{r}\,ds\,ds',$$

[1] 'Die mathematischen Gesetze der inducirten electrischen Ströme,' *Schriften der Berliner Academie der Wissensch.*, 1845.

where A is a constant which depends upon the unit of current, r is the distance between the elements, and ε the angle between their directions. F. E. Neumann showed that this assumption leads to the same law of force between two closed circuits as that given by Ampère, and also explained by means of it the induction of electric currents. v. Helmholtz [1] has investigated the most general expression for the energy possessed by two elements of current which is consistent with the condition that the force between two closed circuits should be the same as that given by Ampère's theory. We shall consider this theory in detail, as it includes all theories of this class, and we shall wish to refer to it when we come to discuss the relative merits of the various theories. v. Helmholtz begins by showing that the most general expression for the energy of two elements of circuit consistent with Ampère's laws for closed circuits is

$$\tfrac{1}{2}\,\frac{A^2\,\iota\,\iota'}{r}\,\{(1+k)\cos\varepsilon + (1-k)\cos\theta\cos\theta'\}\,ds\,ds',$$

where θ and θ' are respectively the angles ds and ds' make with the line joining the elements, k is a constant, and the other symbols have the same meaning as before.

Let us call this quantity T; then we know that T denotes the existence of a force $d\text{T}/dr$ or

$$-\tfrac{1}{2}\,\frac{A^2\,\iota\,\iota'}{r^2}\,\{(1+k)\cos\varepsilon + (1-k)\cos\theta\cos\theta'\}\,ds\,ds'$$

along r, and a force $-d\text{T}/rd\theta$ at right angles to r in the plane of ds and r, and in such a direction that it tends to diminish θ; this force equals

$$\tfrac{1}{2}\,\frac{A^2\,\iota\,\iota'}{r^2}(1-k)\left(\sin\theta\cos\theta' + \cos\theta\sin\theta'\,\frac{d\theta'}{d\theta}\right);$$

and since

$$\frac{d\theta'}{d\theta} = \cos\eta,$$

where η is the angle between the plane containing r and ds and that containing r and ds', the transverse force

$$= \tfrac{1}{2}\,\frac{A^2\,\iota\,\iota'}{r^2}(1-k)\,\{\sin\theta\cos\theta' + \cos\theta\sin\theta'\cos\eta\}.$$

We see that these forces will coincide with those assumed in Korteweg's theory if the quantities a, b, c, d, which occur in that theory, have the following values:

$$\begin{aligned} a &= -A^2 \\ b &= -\tfrac{1}{2}(1+k)\,A^2 \\ c &= \tfrac{1}{2}(1-k)\,A^2 \\ d &= \tfrac{1}{2}(1-k)\,A^2. \end{aligned}$$

So that whatever be the value of k, these quantities satisfy the condition

$$2a + b + c - 2d = -3A^2.$$

[1] Crelle, lxxii. p. 57; *Gesammelte Werke*, vol. i. p. 545.

According to Stefan, it is necessary if two circuits have a potential that

$$2a + b + c - 2d = 0.$$

But Stefan did not consider the couple exerted by one element of circuit on another. The couples acting on the element ds' will be as follows. There will be a couple tending to increase θ', *i.e.* a couple whose axis is at right angles to both ds' and r, equal to $dT/d\theta'$, *i.e.* to

$$\tfrac{1}{2}\,\frac{A^2\,\iota\,\iota'}{r}\{(1+k)\sin\theta\cos\theta'\cos\eta - 2\cos\theta\sin\theta'\},$$

and another couple tending to increase η, *i.e.* a couple whose axis is along the line joining the elements equal to $dT/d\eta$, *i.e.* to

$$-\tfrac{1}{2}\,\frac{A^2\,\iota\,\iota'}{r}(1+k)\sin\theta\sin\theta'\sin\eta.$$

We see that these will agree with the couples in Korteweg's theory of

$$f = -\frac{A^2}{r}; \qquad g = -\tfrac{1}{2}A^2\,\frac{(1+k)}{r}; \qquad h = \tfrac{1}{2}A^2\,\frac{(1+k)}{r}.$$

Let us return to the consideration of the energy of the circuits, and suppose that, instead of currents flowing along linear circuits, we have a distribution of them throughout space. If u, v, w be the currents in the element dx, dy, dz, then the part of the energy contributed by this element will be

$$-A^2\,\{Uu + Vv + Ww\}\,dx\,dy\,dz,$$

where

$$U = \tfrac{1}{2}\iiint\left\{(1+k)\frac{u}{r} + (1-k)\frac{x-\xi}{r^2}\,\{u(x-\xi) + v(y-\eta) + w(z-\zeta)\}\right\}d\xi\,d\eta\,d\zeta,$$

with symmetrical expressions for V and W, where

$$r^2 = (x-\xi)^2 + (y-\eta)^2 + (z-\zeta)^2.$$

We may write the expressions for U, V, W in the form

$$U = \tfrac{1}{2}(1-k)\frac{d\psi}{dx} + \iiint\frac{u}{r}\,d\xi\,d\eta\,d\zeta$$

$$V = \tfrac{1}{2}(1-k)\frac{d\psi}{dy} + \iiint\frac{v}{r}\,d\xi\,d\eta\,d\zeta$$

$$W = \tfrac{1}{2}(1-k)\frac{d\psi}{dz} + \iiint\frac{w}{r}\,d\xi\,d\eta\,d\zeta,$$

where $\psi = \iiint\left(u\,\frac{dr}{d\xi} + v\,\frac{dr}{d\eta} + w\,\frac{dr}{d\zeta}\right)d\xi\,d\eta\,d\zeta$

If u, v, w are the components of the ordinary conduction current, e the volume density of the free electricity, then

$$\frac{du}{dx} + \frac{dv}{dy} + \frac{dw}{dz} = -\frac{de}{dt};$$

and if l, m, n be the direction cosines of the normal to a surface at which

the currents become discontinuous, σ the surface density of the electricity on this surface, then

$$l\,(u-u^1) + m\,(v-v^1) + n\,(w-w^1) + \frac{d\sigma}{dt} = 0.$$

Remembering these equations, ψ may be transformed into

$$\iiint r\,\frac{de}{dt}\,dx\,dy\,dz + \iint r\,\frac{d\sigma}{dt}\,ds\,;$$

or if ϕ denote the electrostatic potential of the free electricity, we see

$$\psi = -\frac{1}{2\pi}\iiint \frac{1}{r}\,\frac{d\phi}{dt}\,dx\,dy\,dz.$$

Substituting this value of ψ we find

$$\nabla^2\mathrm{U} = (1-k)\frac{d^2\phi}{dx\,dt} - 4\pi u,$$

$$\nabla^2\mathrm{V} = (1-k)\frac{d^2\phi}{dy\,dt} - 4\pi v,$$

$$\nabla^2\mathrm{W} = (1-k)\frac{d^2\phi}{dz\,dt} - 4\pi w.$$

We also see that

$$\frac{d\mathrm{U}}{dx} + \frac{d\mathrm{V}}{dy} + \frac{d\mathrm{W}}{dz} = -k\frac{d\phi}{dt}.$$

In order to get the equations connecting the electromotive force with the variation of the electrodynamic potential, Neumann made use of Lenz's law, and assumed that, since by that law the electromotive force tending to increase the current in an element of circuit moving with a velocity w in the direction s would be of the same sign as

$$-\mathrm{X}w,$$

where X is the force along s on the element per unit of length per unit of current flowing through it, it was actually equal to this quantity multiplied by a constant c, *i.e.* to

$$-c\mathrm{X}w\,;$$

but if Ti ds be the energy of the element of current whose length is ds, and current strength i,

$$\mathrm{X} = \frac{d\mathrm{T}}{ds},$$

and

$$w = \frac{ds}{dt}\,;$$

so that the electromotive force per unit of length of the element

$$= -c\,\frac{d\mathrm{T}}{ds}\,\frac{ds}{dt}$$

$$= -c\,\frac{d\mathrm{T}}{dt}.$$

v. Helmholtz has shown that it follows from the principle of the Conservation of Energy that if the energy in the elements dx, dy, dz, traversed by currents u, v, w, be

$$A^2 (Uu+Vv+Ww)\, dx\, dy\, dz,$$

then the components of the electromotive force parallel to the axes x, y, z respectively, due to the variation in the electrodynamic potential, will be

$$-A^2\frac{dU}{dt},\ -A^2\frac{dV}{dt},\ -A^2\frac{dW}{dt};$$

the free electricity produces an electromotive force whose components are

$$-\frac{d\phi}{dx},\ -\frac{d\phi}{dy},\ -\frac{d\phi}{dz},$$

so that the total electromotive force parallel to x, y, z

$$=-\frac{d\phi}{dx}-A^2\frac{dU}{dt}.$$

Now if σ be the specific resistance of the conductor, σu equals the electromotive force parallel to the axis of x, so that

$$\sigma u=-\frac{d\phi}{dx}-A^2\frac{dU}{dt};$$

so that by the preceding equations

$$\frac{\sigma}{4\pi}\left\{\nabla^2 U-(1-k)\frac{d^2\phi}{dx\,dt}\right\}=-\frac{d\phi}{dx}-A^2\frac{dU}{dt},$$

with similar equations for V, W. The quantities U, V, W and their first differential coefficients with respect to x, y, z are continuous, and these equations enable us to find them if we know the value of ϕ, the potential of the free electricity. Helmholtz shows that the whole energy in the field due to the currents may be written

$$\frac{A^2}{8\pi}\iiint\left\{\left(\frac{dU}{dy}-\frac{dV}{dz}\right)^2+\left(\frac{dV}{dz}-\frac{dW}{dy}\right)^2+\left(\frac{dW}{dy}-\frac{dU}{dz}\right)^2+k\left(\frac{d\phi}{dt}\right)^2\right\}dx\,dy\,dz,$$

so that if k be negative, this expression may become negative, and in that case the equilibrium would be unstable; hence we conclude that only those theories are tenable for which k is positive.

The equations written above are those which hold in a conductor, in an insulator the equations are

$$\nabla^2 U=(1-k)\frac{d^2\phi}{dx\,dt}$$

$$\nabla^2 V=(1-k)\frac{d^2\phi}{dy\,dt}$$

$$\nabla^2 W=(1-k)\frac{d^2\phi}{dz\,dt}$$

$$\nabla^2\phi=0.$$

v. Helmholtz shows that in the conductor the electrostatic potential ϕ satisfies the equation

$$\nabla^2\left\{\phi+\frac{\sigma}{4\pi}\frac{d\phi}{dt}\right\}=A^2 k\frac{d^2\phi}{dt^2},$$

so that if the conductor has an infinitely small resistance, the equation becomes

$$\nabla^2\phi = A^2 k \frac{d^2\phi}{dt^2}.$$

This represents a wave motion, the velocity of propagation of which is $1/A\sqrt{k}$. If k, as in Neumann's theory, be equal to unity, then the velocity of propagation is $1/A$, and from the value of A, found from experiments on the force between circuits conveying currents, this is nearly equal to the velocity of propagation of light. Thus, according to Neumann's theory, in a perfect conductor an electrostatic disturbance is propagated with the velocity of light. In an insulator ϕ satisfies the equation

$$\nabla^2\phi = 0;$$

and this represents a motion propagated with an infinite velocity, and thus, according to this theory, an electrostatic disturbance is propagated with an infinite velocity in a perfect non-conductor. In an imperfectly conducting substance the velocity of propagation of a wave motion would depend upon the length of the wave.

Let us now go on to consider, what, according to this theory, are the forces acting on an element of circuit conveying a current. Let us suppose that the element ds forms an element of a circuit through which a current ι is flowing; then the energy of the circuit will be

$$A^2\int \iota\ \left\{U\frac{dx}{ds} + V\frac{dy}{ds} + W\frac{dz}{ds}\right\} ds.$$

In order to find the force parallel to x, let us suppose that each element of the circuit receives an arbitrary displacement x, parallel to the axis of x; then the alteration in the energy will be

$$A^2\int \iota\ \left\{\frac{dU}{dx}\frac{dx}{ds} + \frac{dV}{dx}\frac{dy}{ds} + \frac{dW}{x}\frac{dz}{ds}\right\}\delta x\, ds + A^2\int \iota\, U\ \frac{d\,.\delta x}{ds}\, ds.$$

Integrating the second term by parts, we see that it may be written

$$[A^2\iota U\delta x] - A^2\int \iota\ \left\{\frac{dU}{dx}\frac{dx}{ds} + \frac{dU}{dy}\frac{dy}{ds} + \frac{dW}{dz}\frac{dz}{ds}\right\}\delta x\, ds.$$

Substituting this value for the second term, we see that the alteration in the energy,

$$= [A^2\iota U\delta x] + A^2\int \iota\ \left\{\frac{dy}{ds}\left(\frac{dV}{dx} - \frac{dU}{dy}\right) - \frac{dz}{ds}\left(\frac{dU}{dz} - \frac{dW}{dx}\right)\right\}\delta x\, ds;$$

hence we see by the Conservation of Energy that there is a force on each element of current parallel to the axis of x, equal to

$$\iota\left\{\frac{dy}{ds}\left(\frac{dV}{dx} - \frac{dU}{dy}\right) - \frac{dz}{ds}\left(\frac{dU}{dz} - \frac{dW}{dx}\right)\right\}A^2,$$

and by symmetry forces parallel to y and z equal respectively to

$$\iota\left\{\frac{dz}{ds}\left(\frac{dW}{dy} - \frac{dV}{dz}\right) - \frac{dx}{ds}\left(\frac{dV}{dx} - \frac{dU}{dy}\right)\right\}A^2;$$

$$\iota\left\{\frac{dx}{ds}\left(\frac{dU}{dz} - \frac{dW}{dx}\right) - \frac{dy}{ds}\left(\frac{dW}{dy} - \frac{dV}{dz}\right)\right\}A^2$$

so that the resultant of these forces is at right angles to the element. In addition to these forces there are other forces at places where the quantity ιU is discontinuous, or, since U is continuous, at places where ι is discontinuous, whose components parallel to the axes of x, y, z, are respectively

$$A^2U\partial\iota,\ A^2V\partial\iota,\ A^2W\partial\iota;$$

but $\partial\iota$ equals de/dt, the rate at which the free electricity is increasing at the place, so that we have at any place where the free electricity is changing a force whose components are

$$A^2U\frac{de}{dt},$$
$$A^2V\frac{de}{dt},$$
$$A^2W\frac{de}{dt}.$$

We saw before that the force acting on the circuit per unit length is at right angles at each point to the element of circuit at that point, so that, unless a circuit includes places at which the quantity of free electricity is changing, the circuit will behave as if it were acted on by forces which were everywhere normal to the elements on which they act. In the experiments which have been made to test whether the force on the element is at right angles to it, there have been no points where the free electricity is changing, so that these experiments do not contradict Neumann's theory, although, according to it, the force on an isolated element is not necessarily at right angles to that element, for in addition to the forces normal to the element we have forces equal to $A^2U\,de/dt$, $A^2V\,de/dt$, $A^2W\,de/dt$ parallel to x, y, z respectively, acting at the ends, the resultant of these two forces is a force whose components parallel to the axes of x, y, z are respectively

$$\frac{A^2\,de\,dU\,ds}{dt\ ds},$$
$$\frac{A^2\,de\,dV\,ds}{dt\ ds},$$
$$\frac{A^2\,de\,dW\,ds}{dt\ ds},$$

and as these forces are not necessarily at right angles to the element, the resultant force is not necessarily so; the effect of these forces could not, however, be detected unless there was a discontinuity in the current.

v. Helmholtz in the memoir[1] which we have already quoted shows that, according to his extension of F. E. Neumann's theory, the forces between two elements of circuit ds and ds' may be looked upon as made up of—

(1) A repulsive force on ds due to an end of ds', equal (per unit length) to

$$-A^2\iota\frac{de'}{dt}\frac{1}{r}\frac{dr}{ds};$$

[1] *Ueber die Theorie der Elektrodynamik*, dritte Abhandlung, Crelle, lxxviii. pp. 273, 324, 1874; *Gesammelte Werke*, p. 723.

(2) A repulsive force on ds due to ds', equal per unit length to

$$-\frac{A^2\iota'}{r^2}\left\{2\cos(ds\,ds') - 3\cos(r\,ds)\cos(r\,ds')\right\};$$

(3) A repulsion between the ends of ds and ds', equal to

$$-\frac{1}{2}(1+k)\,A^2\frac{de}{dt}\frac{de'}{dt};$$

(4) A repulsion on ds', due to an end of ds equal per unit length to

$$-A^2\iota'\frac{de}{dt}\frac{1}{r}\frac{dr}{ds}.$$

The second of these is the only one considered in Ampère's theory. We must remember in calculating these forces that each element has two ends.

Let us now go on to find the couples acting at each point of the circuit. If the tangent to the circuit makes an angle θ with the axis of z, and the plane containing the tangent and the axis of z an angle ϕ with the plane of xz, then we may write

$$\frac{dx}{ds} = \sin\theta\cos\phi,$$

$$\frac{dy}{ds} = \sin\theta\sin\phi,$$

$$\frac{dz}{ds} = \cos\theta,$$

so that with the same notation as before the energy equals

$$A^2\int\iota\left(U\frac{dx}{ds} + V\frac{dy}{ds} + W\frac{dz}{ds}\right)ds$$

$$= A^2\int\iota\,(U\sin\theta\cos\phi + V\sin\theta\sin\phi + W\cos\theta)\,ds,$$

so that if ϕ increase by $\delta\phi$, the alteration in the energy equals

$$A^2\int\iota\,(-U\sin\theta\sin\phi + V\sin\theta\cos\phi)\,\delta\phi\,ds,$$

so that the couple tending to increase ϕ, *i.e.* the couple whose axis is parallel to the axis of z, equals

$$A^2\iota\,(V\sin\theta\cos\phi - U\sin\theta\sin\phi)$$

per unit length of current; this may be written

$$A^2\iota\left(V\frac{dx}{ds} - U\frac{dy}{ds}\right),$$

hence the couples parallel to the axes of y and x are by symmetry respectively

$$A^2\iota\left\{U\frac{dz}{ds} - W\frac{dx}{ds}\right\},$$

$$A^2\iota\left\{W\frac{dy}{ds} - V\frac{dz}{ds}\right\}.$$

The axis of the resultant couple is perpendicular to the element and to the vector whose components are U, V, W.

In another paper[1] v. Helmholtz discusses the force acting per unit of volume on a conductor traversed by electric currents; he shows that, according to the potential theory, if u, v, w are the components of current through an element $dx\,dy\,dz$, and X, Y, Z the components of the force acting on this element of volume per unit of volume, then

$$\mathrm{X}=\mathrm{A}^2\left[v\left(\frac{d\mathrm{V}}{dx}-\frac{d\mathrm{U}}{dy}\right)+w\left(\frac{d\mathrm{W}}{dx}-\frac{d\mathrm{U}}{dz}\right)+\mathrm{U}\frac{de}{dt}\right]$$

$$\mathrm{Y}=\mathrm{A}^2\left[u\left(\frac{d\mathrm{U}}{dy}-\frac{d\mathrm{V}}{dx}\right)+w\left(\frac{d\mathrm{W}}{dy}-\frac{d\mathrm{V}}{dz}\right)+\mathrm{V}\frac{de}{dt}\right]$$

$$\mathrm{Z}=\mathrm{A}^2\left[u\left(\frac{d\mathrm{U}}{dz}-\frac{d\mathrm{W}}{dx}\right)+v\left(\frac{d\mathrm{V}}{dz}-\frac{d\mathrm{W}}{dy}\right)+\mathrm{W}\frac{de}{dt}\right]$$

He then discusses the application of the potential law to sliding contacts, that is, contacts such as those made by a wire dipping into mercury; in the derivation of the forces from the potential law it is assumed that the displacements are continuous, and it might be objected that we have no right to apply the law in this case as the motion of the wire and the mercury seems at first sight discontinuous. v. Helmholtz, however, points out that, as the wire carries the mercury with it as it moves, the motion is not really discontinuous and that Neumann's law is applicable. The question of sliding contacts comes prominently forward when we compare the various theories; we shall return to it again in this connection.

v. Helmholtz also in this paper investigates the electromotive forces acting on a conductor in motion; he shows that if the components of the velocity of the conductor at any point are α, β, γ, then P, Q, R, the components of the electromotive force, are given by the equation

$$\mathrm{P}=\beta\left(\frac{d\mathrm{U}}{dy}-\frac{d\mathrm{V}}{dx}\right)+\gamma\left(\frac{d\mathrm{U}}{dz}-\frac{d\mathrm{W}}{dx}\right)+\frac{d}{dx}(\mathrm{U}\alpha+\mathrm{V}\beta+\mathrm{W}\gamma),$$

with similar equations for Q and R.

He also investigates the difference between the results of Ampère's and Neumann's theory for the E.M.F. due to induction. The results are complicated; for practical purposes it is sufficient to notice that when there is a mechanical force tending to make the body move in a certain direction, there must be an E.M.F. when the body moves in that direction.

C. Neumann's Theory.

C. Neumann assumes that the electric potential energy is propagated with a finite velocity, and that if two electrified bodies are in motion, the mutual potential energy is not ee'/r, where r is the distance between them, but ee'/r', where r' is the distance between them at a time t before, where t is the time taken by the potential to travel from the one body to the other.

The energy considered in C. Neumann's theory is a kind of energy quite different from any that we have experience of; it is not poten-

[1] *Ueber die Theorie der Elektrodynamik*, Crelle, lxxviii. pp. 273–324, 1874; *Gesammelte Werke*, vol. ii. p. 703.

tial energy, because that at any time depends only on the position of the system at that time; it is not kinetic, because that depends only on the position and velocity of the system at the time under consideration, whilst Neumann's energy depends on the velocity and position of the system at some previous time. In spite of all this, however, Neumann applies the ordinary dynamical processes to this energy just as if it were kinetic or potential; and in this way arrives at the same expression as Weber for the force between two moving electrified bodies. The rest of the theory is the same as Weber's, except that Neumann's assumption about the nature of a current is different from Weber's. According to Weber, an electric current consists of equal quantities of positive and negative electricity, moving with equal velocities in opposite directions. According to Neumann, the positive electricity alone can move, the negative being attached to the molecules of the conductor. Riecke and Clausius have shown that with this assumption and Weber's law a steady current must exert a force upon a particle at rest and charged with electricity, and must in consequence produce an irregular distribution of electricity over any conductor in its neighbourhood.

Theories which are founded on dynamical considerations and which take into account the action of the dielectric.

In the theories we have hitherto considered, the influence of the medium which exists between the currents has been left altogether out of account. In the theories which we shall now proceed to discuss, the influence of this medium is taken into consideration. This is, perhaps, the most important step that has ever been made in the theory of electricity, though from a practical point of view it is comparatively of little importance; in fact, for practical purposes almost any one of the preceding theories will satisfy every requirement.

Faraday was the first to look upon the dielectric as an important agent in electrical phenomena; he was led to this by his desire to get rid, as far as possible, of the idea of action at a distance, which was so prevalent in his time, but to which his researches have given the death-blow. In his 'Experimental Researches,' § 1164, speaking of electrostatic induction, he says, 'I was led to suspect that common induction itself was in all cases an action of contiguous particles, and that electrical action at a distance (*i.e.* ordinary inductive action) never occurred except through the influence of surrounding matter.' And later on he gives his views as to the nature of the effect in the medium; in § 1298 of the 'Researches' he says, 'Induction appears to consist in a certain polarised state of the particles into which they are thrown by the electrified body sustaining the action, the particles assuming positive and negative points or parts, which are symmetrically arranged with respect to each other and the inducting surfaces or particles. This state must be a forced one, for it is originated and sustained only by force, and sinks to the normal or quiescent state when that force is removed. It can be continued only in insulators by the same portion of electricity, because they only can retain this state of the particles.' He gives an experimental illustration of his view in § 1350. He says, 'As an illustration of the condition of the polarised particles in a dielectric under induction I may describe an experiment. Put in a glass vessel some clear rectified

oil of turpentine, and introduce two wires passing through glass tubes, when they coincide with the surface of the fluid and terminating in balls or points. Cut some very clean dry white silk into small particles, and put these also into the liquid; then electrify one of the wires by an ordinary machine and discharge by the other. The silk will immediately gather from all parts of the liquid and form a band of particles reaching from wire to wire, and if touched by a glass rod will show considerable tenacity; yet the moment the supply of electricity ceases the band will fall away and disappear by the dispersion of its parts. The conduction by the silk is in this case very small, and after the best examination I could give to the effects, the impression on my mind is that the adhesion of the whole is due to the polarity which each filament acquires, exactly as the particles of iron between the poles of a horse-shoe magnet are held together in one mass by a similar disposition of forces. The particles of silk therefore represent to me the condition of the molecules of the dielectric itself, which I assume to be polar, just as that of the silk is. In all cases of conductive discharge the contiguous polarised particles of the body are able to effect a neutralisation of their forces with greater or less facility, as the silk does also in a very slight degree. Further we are not able to carry the parallel, except in imagination; but if we could divide each particle of silk into two halves, and let each half travel until it met and united with the next half in an opposite state, it would then exert its carrying power (1307), and so far represent electrolytic discharge.'

And it is not only in statical electricity that Faraday recognised the importance of the dielectric. When he is discussing his discovery of the induction of currents, which he ascribes to the assumption of what he called the electrotonic state by the body in which induced currents are developed, he says, § 73, 'It may even exist in non-conductors,' that is, that there is an electromotive force acting on the surrounding dielectric due to the variation in the primary current. Again, in § 1661, he says, 'Now though we perceive the effects only in that portion of matter which, being in the neighbourhood, has conducting properties, yet hypothetically it is probable that the non-conducting matter has also its relations to, and is affected by, the disturbing causes, though we have not yet discovered them. Again and again the relation of conductors and non-conductors has been shown to be one, not of opposition in kind, but only in degree (1334, 1603); and therefore for this, as well as for other reasons, it is probable that what will affect a conductor will affect an insulator also, producing, perhaps, what may deserve the term of the electrotonic state (60, 242, 1114).' And though he was unable to detect these effects experimentally, the following paragraph (1728) shows that his belief in their existence was not shaken: 'But then it may be asked, What is the relation of the properties of insulating bodies, such as air, sulphur, or lac, when they intervene in the line of magnetic action? The answer to this is at present merely conjectural. I have long thought there must be a particular condition of such bodies, corresponding to the state which causes currents in metals and other conductors (26, 53, 191, 201, 213); and considering that the bodies are insulators, one could expect that state to be one of tension. I have, by rotating non-conducting bodies near magnetic poles, and poles near them, and also by causing powerful electric currents to be suddenly formed and to cease around and about insulators in various directions, endeavoured to make some

such state sensible, but have not succeeded. Nevertheless as any such state must be of exceedingly low intensity, because of the feeble intensity of the currents which are used to induce it, it may well be that the state may exist, and may be discoverable by some more expert experimentalist, though I have not been able to make it sensible.'

Maxwell was the first to express Faraday's ideas in mathematical language. In his papers on 'Physical Lines of Force' in the 'Philosophical Magazine' for March, April, May, 1861, and January, February, 1862, he developes a theory of electricity according to which the energy of the electro-magnetic field resides in the dielectric as well as in the conductors; later, in the 'Philosophical Transactions' for 1865, he greatly extended Faraday's ideas as well as put them into definite mathematical language, and this without reference to any special theory of the mechanism which produces electrical phenomena. We shall devote some time to discussing Maxwell's theory, as it is freer from serious objections than any other, while at the same time it covers a much wider ground.

We shall begin by referring to Maxwell's view of the state of the dielectric in the electric field. Maxwell supposes that the dielectric is changed, and perhaps the clearest way of describing this change is that of Faraday in the extract already quoted. Maxwell's nomenclature as to this change is a little unfortunate; instead of speaking, like Faraday, of the polarisation of the dielectric, he speaks of the change as consisting of an electric displacement, which in isotropic media is in the direction of the electromotive force. Mathematically the two things are identical; we may either say of a wire that it is negatively electrified at one end A, and positively at the other end B, or else that there is a displacement of positive electricity from A to B, so that there is an excess of positive electricity at B and a deficiency at A. But though the words in a mathematical sense are identical, still the word displacement seems to connote special qualities which limit the generality of the conception in an undesirable way; the word displacement seems to imply motion in the direction of displacement, while polarisation only implies that there is a vector change of some kind in the dielectric. The condition of the dielectric is quite analogous to the state of a piece of soft iron placed in a magnetic field. The polarisation or displacement is in isotropic media in the direction of the electromotive force and proportional to it, just as the magnetic induction in isotropic media is in the direction of the magnetic force and proportional to it. It was this proportionality combined with the fact that as soon as the electromotive force is removed the dielectric springs back, as it were, to its original state, that led Maxwell to use the word displacement. He looked on the case as analogous to that of an elastic solid, which springs back to its original position when the external force is removed, and in which the displacement is proportional to the impressed force. To avoid any unnecessary definiteness we shall use the term dielectric polarisation instead of electric displacement. Thus according to this view the dielectric in the electric field is polarised. This polarisation means change of structure of some kind, and to produce this change of structure work is required. The energy in the polarised dielectric will be greater than the energy when it was unpolarised, for if the energy were less the dielectric would go into the polarised condition of itself, without the application of any external forces.

It is rather difficult to see what is meant in Maxwell's theory by the phrase 'quantity of electricity.' According to the old two-fluid theory

an electrified body was supposed to contain a certain quantity of something called electricity, rules were given for measuring this quantity, and the phrase 'quantity of electricity' meant something quite definite. In Maxwell's theory, where everything is referred to the dielectric, the meaning of the phrase is not so obvious. We can, however, arrive at some idea of what is meant by the consideration of what are called 'tubes of force.' Let us suppose at first that the dielectric is air. A line of force is a line whose direction at any point coincides with the direction of the electromotive force at that point, so that we may conceive the electric field to be filled with lines of force. If we consider the lines of force passing through some small closed curve, they will form a tube, and such a tube is called a tube of force; and if the dimensions of the tube are such that the product of the cross section at any point and the electromotive force at that point is constant and equal to 4π, the tube is called a unit tube. We may thus conceive space to be filled with unit tubes of force. Since the electromotive force inside a conductor vanishes these tubes will end at the surface of a conductor. And the quantity of electricity on the conductor will be equal to the excess of the number of lines of force which leave the conductor over those which enter it. A tube is said to leave the conductor when the direction of the electromotive force is along the normal drawn outwards, and to enter it when the direction of the electromotive force is along the normal drawn inwards. As the conductor moves about it may be supposed to carry the tubes of force along with it, so that the number of tubes which end on the conductor remains constant. This way of looking at electrification is quite satisfactory as long as we keep to one dielectric air; when we have to consider different dielectrics it requires modification, because the electromotive force changes abruptly as we pass from one dielectric into another, so that a tube which was a unit tube in one dielectric is not so in another. It is easy, however, to extend the definition of unit tubes so as to meet this difficulty; for if the tubes pass from one dielectric A into another B the ratio of the product of the cross section and electromotive force is constant for all the tubes and depends only on the nature of the dielectrics; this ratio is the ratio of the specific inductive capacities in B and A. Air is taken as the standard dielectric, and the specific inductive capacity of another dielectric A is the ratio of the product of the electromotive force and cross section of a tube in air to the product of the same quantities for the same tube in the dielectric A. Thus if we amend our definition and say that a circuit tube is one such that the product of the cross section, the electromotive force, and the specific inductive capacity of the medium in which the cross section is situated is equal to 4π, then the quantity of electricity on a conductor is equal to the excess of the number of unit tubes which leave the conductor over the number of those which enter it. In this way we get an idea of what is meant by 'quantity of electricity' in Maxwell's theory. Maxwell accounts for the forces observed between electrified bodies by a system of stresses in the dielectric separating them; as, however, at present we wish to compare Maxwell's theory with other theories which do not touch upon this point, we shall discuss this part of the theory separately later on and go on to discuss those points which are involved in all the theories.

The next great point in Maxwell's theory is the development of Faraday's remark that the electrotonic state may exist even in non-conductors, *i.e.*, that the dielectric surrounding a changing current is acted

on by electromotive forces which polarise it. This statement is one as to whose truth nobody seems to entertain any doubt, whilst the statement that changes in the dielectric polarisation produce effects analogous to those produced by ordinary conduction currents is by no means so universally received, and yet the one seems the necessary consequence of the other. If we regard the whole electric field as a dynamical system, and to fix our ideas consider an element a of the dielectric, and the current, which is supposed to vary, then, since a variation in the current polarises a, *i.e.*, produces a change in its structure, there must be mechanism connecting the current with the element a; but if this is so then it follows from dynamical principles that a non-uniform variation in the structure of a must produce a change in the current—in other words, that a change in the rate of change of the polarisation of a produces an electromotive force on the current, *i.e.* that the change of polarisation produces an effect analogous to that of an ordinary conduction current. We may illustrate this by a purely dynamical example. Suppose we have a dynamical system defined by two co-ordinates p and q, and let T be the kinetic energy of the system and V the potential energy; then by Lagrange's equation the force tending to increase q

$$= -\frac{dV}{dq} + \frac{dT}{dq} - \frac{d}{dt}\frac{dT}{d\dot{q}}.$$

Now if there is a force tending to alter q which depends upon the acceleration of p, there must be a term in the kinetic energy of the form

$$A\dot{p}\dot{q};$$

but if we apply Lagrange's equations to the p co-ordinates we see that this term implies the existence of a force tending to increase p equal to

$$-\frac{d}{dt}A\dot{q},$$

so that an acceleration of q will produce a force tending to alter p. To make this applicable to the case of the current and the dielectric, we have only to suppose that $\dot{p}$ represents the current, q the polarisation of the dielectric. That a change in $\dot{p}$ produces a change in q is shown by the fact that the dielectric is polarised when the current is changing, and this shows that there must be a term of the form $A\dot{p}\dot{q}$, in expression for the kinetic energy; from this it follows that a change in $\dot{q}$, *i.e.*, in the rate of change of the polarisation, will produce an E.M.F. on the circuit. As the variation of the dielectric polarisation produces the same effect as a conduction current, we must in the case, when both conduction current and alteration in the polarisation are present, look upon the true or effective current as the sum of the conduction current and the change in the polarisation.

The components f, g, h of the dielectric polarisation are defined by the equation

$$f = \frac{K}{4\pi}X \qquad g = \frac{K}{4\pi}Y \qquad h = \frac{K}{4\pi}Z,$$

where K is the specific inductive capacity of the medium, X, Y, Z the components of the electromotive force. If u, v, w are the components of the effective current, p, q, r the components of the conduction

current, then Maxwell in his paper on a 'Dynamical Theory of the Electromagnetic Field,' 'Phil. Trans., 1885,' puts

$$u = p + \frac{df}{dt}, \qquad v = q + \frac{dg}{dt}, \qquad w = r + \frac{dh}{dt}.$$

Since
$$\frac{dp}{dx} + \frac{dq}{dy} + \frac{dr}{dz} = -\frac{d\rho}{dt}$$

and
$$\frac{df}{dx} + \frac{dg}{dy} + \frac{dh}{dz} = \rho,$$

where ρ is the volume density of the free electricity, we see that

$$\frac{du}{dx} + \frac{dv}{dy} + \frac{dw}{dz} = 0.$$

If the values of the quantities in a medium A be denoting by putting the suffix 1 to the symbols representing them, and those in another dielectric B by putting the suffix 2, then if l, m, n are the direction cosines of the normal from A to B, we have at the boundary of the two media

$$l\,(p_1 - p_2) + m\,(q_1 - q_2) + n\,(r_1 - r_2) = \frac{d\sigma}{dt}$$

$$l\,(f_1 - f_2) + m\,(g_1 - g_2) + n\,(h_1 - h_2) = -\sigma,$$

where σ is the surface density of the electricity; thus

$$l\,(u_1 - u_2) + m\,(v_1 - v_2) + n\,(w_1 - w_2) = 0;$$

so that u, v, w satisfy the same equations as the components of the velocity of an incompressible fluid.

This assumption about the magnitude of the effects produced by the alteration in the dielectric polarisation makes the mathematics of the theory as simple as possible. If Maxwell had merely assumed that the alteration of the dielectric polarisation produces effects analogous to those produced by ordinary conduction currents, and that the equivalent conduction current was proportional to the rate of alteration of the dielectric polarisation, then these equations would have been

$$u = p + \alpha \frac{dX}{dt},$$

$$v = q + \alpha \frac{dY}{dt},$$

$$w = r + \alpha \frac{dZ}{dt};$$

so that in a homogeneous dielectric

$$\frac{du}{dx} + \frac{dv}{dy} + \frac{dw}{dz} = -\frac{d\rho}{dt}\left\{1 - 4\frac{\alpha\pi}{k}\right\},$$

$$l(u_1 - u_2) + m\,(v_1 - v_2) + n\,(w_1 - w_2) = \frac{d\sigma}{dt} + \alpha_1 \frac{dN_1}{dt} - \alpha_2 \frac{dN_2}{dt}$$

where N is the component of the electromotive force normal to the surface.

Maxwell's assumption is that $a = \mathrm{K}/4\pi$, and this makes the equations much simpler; it is, however, important to remember that Maxwell's theory of the dielectric involves the two assumptions—

1st. That alterations in the dielectric polarisation produce effects analogous to those of ordinary conduction currents;

2nd. That the magnitude of the equivalent conducting current $= d\left\{\frac{\mathrm{K}}{4\pi}\mathrm{F}\right\}/dt$, where F is the electromotive force at the point; this is equivalent to saying that all the currents are closed currents, and that there is no discontinuity in them.

Maxwell developes his theory by means of the principle of the Conservation of Energy.

Let us consider an electric field full of currents, whether ordinary conduction currents or polarisation ones. Then this field may be looked upon as a material system, and all the phenomena have to be explained as the effects of the motion of this system; a current must be looked upon as a change in the structure of the system, and so capable of representation by means of the differential coefficients of the co-ordinates fixing the system; we can thus represent the current at each point as the differential coefficient of some generalised co-ordinate fixing the system; the components u, v, w of the current passing through an element dx, dy, dz may be looked upon as the rates of change of some generalised co-ordinates; we may write the energy as

$$\tfrac{1}{2}\iiint \{\mathrm{F}u + \mathrm{G}v + \mathrm{H}w\}\,dx\,dy\,dz,$$

where F, G, H may be looked upon as momenta corresponding to u, v, w. It remains to identify F, G, H with known quantities. Maxwell does this by the aid of Faraday's result, that the electromotive force round a circuit equals the rate of diminution of the number of lines of force passing through it.

Let us consider a single linear circuit in which the current is i, or say dq/dt, then the energy

$$= \tfrac{1}{2}\int \frac{dq}{dt}\left\{\mathrm{F}\frac{dx}{ds} + \mathrm{G}\frac{dy}{ds} + \mathrm{H}\frac{dz}{ds}\right\}ds,$$

where ds is an element of circuit; but by Lagrange's equation the force tending to increase q, *i.e.*, the electromotive force in the circuit,

$$= -\frac{d}{dt}\int\left(\mathrm{F}\frac{dx}{ds} + \mathrm{G}\frac{dy}{ds} + \mathrm{H}\frac{dz}{ds}\right)ds;$$

so that

$$\int\left(\mathrm{F}\frac{dx}{ds} + \mathrm{G}\frac{dy}{ds} + \mathrm{H}\frac{dz}{ds}\right)ds$$

equals the number of lines of force passing through the circuit; but if $d\mathrm{S}$ be an element of surface closing up the circuit, l, m, n the direction cosines of the normal, then by Stokes' theorem

$$\int\left(\mathrm{F}\frac{dx}{ds} + \mathrm{G}\frac{dy}{ds} + \mathrm{H}\frac{dz}{ds}\right)ds$$

$$\iint\left\{l\left(\frac{d\mathrm{H}}{dy} - \frac{d\mathrm{G}}{dz}\right) + m\left(\frac{d\mathrm{F}}{dz} - \frac{d\mathrm{H}}{dx}\right) + n\left(\frac{d\mathrm{G}}{dx} - \frac{d\mathrm{F}}{dy}\right)\right\}d\mathrm{S};$$

but the number of lines of force passing through the circuit

$$=\iint(la+mb+nc)dS,$$

where a, b, c are the components of magnetic induction, so that

$$a=\frac{dH}{dy}-\frac{dG}{dz},$$

$$b=\frac{dF}{dz}-\frac{dH}{dx},$$

$$c=\frac{dG}{dx}-\frac{dF}{dy}.$$

To connect a, b, c with the current, Maxwell makes use of the principle that the line integral of the magnetic force taken round any closed curve equals the current flowing through the curve. This leads to the equations—

$$4\pi u=\frac{d\gamma}{dy}-\frac{d\beta}{dz},$$

$$4\pi v=\frac{d\alpha}{dz}-\frac{d\gamma}{dx},$$

$$4\pi w=\frac{d\beta}{dx}-\frac{d\alpha}{dy};$$

so that if μ be the coefficient of magnetic permeability,

$$4\pi\mu u=\frac{dc}{dy}-\frac{db}{dz},$$

and so on. Substituting the values of a, b, c, given above, we find

$$4\pi\mu u=\frac{d}{dx}\left\{\frac{dF}{dx}+\frac{dG}{dy}+\frac{dH}{dz}\right\}-\nabla^2F,$$

with similar equations for G and H.

Now v. Helmholtz, in his paper 'Ueber die Bewegungsgleichungen der Elektricität für ruhende leitende Körper' (Crelle, lxxii. p. 57; *Gesammelte Werke*, ii. p. 545), has investigated the most general expressions for F, G, H, consistent with the force between two closed circuits agreeing with that indicated by Ampère's theory, and he finds that if the circuits are closed circuits, as Maxwell assumes all circuits to be, then

$$\frac{dF}{dx}+\frac{dG}{dy}+\frac{dH}{dz}=0,$$

and therefore $$4\pi\mu u=-\nabla^2F,$$

with similar equations for G and H. These equations are sufficient to determine the quantities F, G, H.

Maxwell does not at once put $dF/dx+dG/dy+dH/dz=0$; he writes J for this quantity, and puts

$$\chi=\iiint\frac{J}{r}dx\,dy\,dz.$$

Then $$F=\iiint\frac{\mu u}{r}dx\,dy\,dz+\frac{d\chi}{dx};$$

as, however, he subsequently puts $J=0$, we may at once simplify the equation by making this assumption.

Since the kinetic energy equals

$$\tfrac{1}{2}\iiint(Fu+Gv+Hw)\,dx\,dy\,dz,$$

we see by Lagrange's equations that the electromotive force tending to increase u

$$=-\frac{dF}{dt};$$

in addition to this there is the force arising from the electrostatic potential ϕ, so that the total electromotive force parallel to the axis of x

$$=-\frac{dF}{dt}-\frac{d\phi}{dx},$$

so that if σ be the specific resistance of the substance, K its specific inductive capacity, then

$$\sigma p=\frac{4\pi}{K}f=-\frac{dF}{dt}-\frac{d\phi}{dx};$$

but
$$u=p+\frac{df}{dt}=-\frac{1}{\sigma}\left\{\frac{dF}{dt}+\frac{d\phi}{dx}\right\}-\frac{K}{4\pi}\left\{\frac{d^2F}{dt^2}+\frac{d^2\phi}{dx\,dt}\right\};$$

but we saw before that

$$4\pi\mu u=-\nabla^2F;$$

substituting for u this value, we see

$$\nabla^2F=\frac{4\pi\mu}{\sigma}\left\{\frac{dF}{dt}+\frac{d\phi}{dx}\right\}+K\mu\left\{\frac{d^2F}{dt^2}+\frac{d^2\phi}{dx\,dt}\right\},$$

thus in the dielectric the equation becomes

$$\nabla^2F=K\mu\left\{\frac{d^2F}{dt^2}+\frac{d^2\phi}{dx\,dt}\right\},$$

in the conductor

$$\nabla^2F=\frac{4\pi\mu}{\sigma}\left\{\frac{dF}{dt}+\frac{d\phi}{dx}\right\}.$$

The equation for the dielectric shows that it represents a wave-motion propagated with the velocity $1/\sqrt{K\mu}$; the numerical value of this velocity agrees very approximately with the velocity of light, and this led Maxwell to the theory that the changes in the structure of the dielectric which take place when the dielectric is polarised are of the same nature as those which constitute light. This theory, which is called the electromagnetic theory of light, might almost as justly be called the mechanical theory of dielectric polarisation. Kirchhoff, in his paper 'Ueber die Bewegung der Electricität in Drähten' (Pogg. *Ann.*, vol. c. 1857; *Gesammelte Werke*, p. 131), was the first to point out that some electrical actions are propagated with the velocity of light. In this paper he considers the motion of electricity in wires whose diameters are small compared with their length. There are three things which have to be considered in this problem—(1) the self-induction of the electric current, and

if the medium be taken into account, that of the polarisation currents in the dielectric. This self-induction produces very much the same effect as if the electric current possessed momentum—(2) the electrostatic action of the free electricity which tends to bring things to a definite state, and corresponds very much to the spring in a material system. Then, lastly, there is the electrical resistance, which corresponds to friction in an ordinary system. We see from the analogy that if the resistance be small enough, the electrical system will vibrate; if, however, the resistance is large, the electrical disturbance will be propagated in the same way as heat. Kirchhoff in his paper considers the propagation of electrical disturbance along a wire under various conditions: we shall only consider here one of these cases; that of an endless wire. In his solution Kirchhoff only considers the self-induction of the current flowing along the wire; he does not consider the effects in the surrounding dielectric. He shows that if e be the quantity of electricity per unit length of the wire, and

$$e = \mathrm{X} \sin ns,$$

where s is the length of a portion of the wire measured from some fixed point, then X satisfies the differential equation

$$\frac{d^2\mathrm{X}}{dt^2} + \frac{c^2 r}{16\gamma l}\frac{d\mathrm{X}}{dt} = \frac{c^2}{2}\frac{d^2\mathrm{X}}{ds^2},$$

where c is a quantity which occurs in Weber's theory, and is the velocity with which two charged particles must move if the electrodynamic attraction between them balances the electrostatic repulsion;

r is the resistance of the wire in electrostatic measure; $\gamma = log\ l/a$,

where l is the length of the wire and a the radius of its cross section. The form of the solution of this equation depends on the magnitude of

$$\frac{32\gamma}{cr\sqrt{2}} nl.$$

If this quantity be large, the solution takes the form representing the propagation of a wave along the wire with the velocity $c/\sqrt{2}$. Weber's researches show that this velocity is very nearly equal to the velocity of light. If, however, the above-mentioned quantity be small, then the solution of the equation takes the same form as the formula which expresses the conduction of heat along the wire. We must not, however, take this to mean that the electric disturbance is propagated with an infinite velocity, so that if we had an infinitely delicate electrometer at a finite distance from the source of disturbance we could detect an electrification after an indefinitely short time, for it seems obvious that the electrical resistance cannot increase the velocity of propagation any more than the resistance of the air could increase the velocity of propagation of a disturbance along a line of particles connected by an elastic string. The conditions at the end help to determine the form of the solution, and these cannot make themselves felt until the disturbance has reached it; thus the heat form of solution probably only holds after a time from the commencement of the disturbance greater than the time taken by light to travel along the wire. If we take the case of a copper wire one square centimetre in area, we shall find that the wave form of solution will hold if the wire is not more than 100 miles in length, while the heat form will correspond to wires which are much longer than this. Kirchhoff's

solution only refers to the propagation of a disturbance in a conductor, while Maxwell's refers to the propagation of such a disturbance in the dielectric.

Maxwell considers the effect of the motion of the medium on the electromotive force; he shows that the electromotive force parallel to the axis of x

$$= cv - bw - \frac{dF}{dt} - \frac{d\psi}{dx},$$

where u, v, w are the components of the velocity of the medium conveying electric action. Here ψ is not the electrostatic potential merely; it is equal, as Helmholtz has shown,[1] to the electrostatic potential plus the term

$$Fu + Gv + Hw.$$

We must remark here that u, v, w are the components of the velocity of the medium conveying the electric action, *i.e.* the ether, and this need not necessarily be the same as the velocity of the dielectric.

v. Helmholtz's Dielectric Theory.

v. Helmholtz, in the paper[2] to which we have so often referred, considers the effect of the polarisation of the dielectric; he supposes that when an electromotive force X, parallel to the axis of x, acts on an element of a dielectric, it puts it into such a state that it produces the same effect as if there were electricity of surface-density $\mathfrak{x}$ on the face $dy\,dz$ of the element, and an equal quantity of electricity of the opposite sign on the parallel face, $\mathfrak{x}$ being given by the equation

$$\mathfrak{x} = \epsilon X,$$

the variations in the electromotive forces acting on the dielectric are supposed to produce the same effect as ordinary conduction currents whose components are $\dot{\mathfrak{x}}, \dot{\mathfrak{y}}, \dot{\mathfrak{z}}$, where $\mathfrak{x}, \mathfrak{y}, \mathfrak{z}$ are the components of a vector quantity which in isotropic media is parallel to the electromotive force and equal to the product of ϵ and the intensity of the force. This agrees with Maxwell's assumption, provided

$$\epsilon = K/4\pi,$$

where K is the specific inductive capacity of the dielectric. If ϕ be the electrostatic potential of the free electricity, ψ the potential due to the polarisation of the dielectric, then Helmholtz shows that

$$\frac{d}{dx}\left\{(1+4\pi\epsilon)\frac{d}{dx}(\phi+\psi)\right\} + \frac{d}{dy}\left\{(1+4\pi\epsilon)\frac{d}{dy}(\phi+\psi)\right\}$$
$$+\frac{d}{dz}\left\{(1+4\pi\epsilon)\frac{d}{dz}(\phi+\psi)\right\} = -4\pi E,$$

where E is the volume-density of the free electricity. The corresponding equation in Maxwell's theory is of the same form, provided

$$1 + 4\pi\epsilon = K.$$

[1] *Ueber die Theorie der Elektrodynamik; die elektrodynamische Kräfte in bewegten Leitern,* Crelle, lxxviii. p. 309; *Gesammelte Werke,* ii. p. 745.

[2] *Ueber die Theorie der Elektrodynamik,* Crelle, lxxii. p. 57; *Gesammelte Werke,* i. p. 544.

This relation seems inconsistent with the previous one; it may, however, be reconciled with it in the following way:—

The potential due to a quantity E of electricity at a point distant r from it is proportional to

$$\frac{E}{(1+4\pi\varepsilon)r}.$$

If ε_0 be the value of ε for air, the potential under the same circumstances in air is proportional to

$$\frac{E}{(1+4\pi\varepsilon_0)r};$$

if, then, we define unit potential as the potential at unit distance from unit of electricity in air, the potential due to a quantity E in another medium will be

$$\left\{\frac{1+4\pi\varepsilon_0}{1+4\pi\varepsilon}\right\}\frac{E}{r}.$$

We see that this is equivalent to increasing the unit of potential, and therefore the unit electromotive force, $1+4\pi\varepsilon_0$ times, so that if we use the new unit the equations will be

$$\mathfrak{x}=\frac{\varepsilon}{1+4\pi\varepsilon_0}X,$$

$$\frac{d}{dx}\left\{\frac{1+4\pi\varepsilon}{1+4\pi\varepsilon_0}\frac{d}{dx}(\phi+\psi)\right\}+\dots\quad=-4\pi E.$$

These will coincide with Maxwell's equation if we make ε and ε_0 each infinite and put $K=\varepsilon/\varepsilon_0$.

Returning to Helmholtz's theory, if u, v, w are the components of the total current

$$u=p+\dot{\mathfrak{x}},$$
$$v=q+\dot{\mathfrak{y}},$$
$$w=r+\dot{\mathfrak{z}},$$

where p, q, r are the components of the conduction current.

Helmholtz puts

$$\frac{du}{dx}+\frac{dv}{dy}+\frac{dw}{dz}=-\frac{d\rho}{dt},$$

where ρ is the volume-density of the free electricity, and if σ be the surface-density of the free electricity at any point of a surface separating two media, u_1, v_1, w_1; u_2, v_2, w_2 the components of the current in the two media, l, m, n the direction cosines of the normal to the surface drawn from the first medium to the second, then according to v. Helmholtz

$$l\,(u_1-u_2)+m\,(v_1-v_2)+n\,(w_1-w_2)=\frac{d\sigma}{dt}.$$

According to Maxwell the corresponding equations are

$$\frac{du}{dx}+\frac{dv}{dy}+\frac{dw}{dz}=0,$$

$$l\,(u_1-u_2)+m\,(v_1-v_2)+n\,(w_1-w_2)=0.$$

As it is in the difference between these equations that the difference in the theory really lies, it will be instructive to look at them from another point of view. We know of no way in which the quantity of free electricity can be altered except by electricity being conveyed by conduction currents to the place where the alteration takes place. Assuming, then, that the alteration in the density is caused by such currents

$$\frac{dp}{dx}+\frac{dq}{dy}+\frac{dr}{dz}=-\frac{d\rho}{dt},$$

$$l\,(p_1-p_2)+m\,(q_1-q_2)+n\,(r_1-r_2)=\frac{d\sigma}{dt}.$$

So that Helmholtz's equations taken in conjunction with these are equivalent to the condition

$$\frac{d\dot{\mathfrak{x}}}{dx}+\frac{d\dot{\mathfrak{y}}}{dy}+\frac{d\dot{\mathfrak{z}}}{dz}=0\,;$$

$$l\,(\dot{\mathfrak{x}}_1-\dot{\mathfrak{x}}_2)+m\,(\dot{\mathfrak{y}}_1-\dot{\mathfrak{y}}_2)+n\,(\dot{\mathfrak{z}}_1-\dot{\mathfrak{z}}_2)=0.$$

Thus on Helmholtz's theory the dielectric currents behave like the flow of an incompressible fluid, while on Maxwell's theory it is the total current, which is the sum of the conduction currents and the dielectric currents which behave in this way.

The equations we have arrived at for the dielectric currents seem inconsistent with Helmholtz's definition of them; for since

$$\mathfrak{x}=\epsilon X,$$

with similar equations for $\mathfrak{y}$ and $\mathfrak{z}$, and since in a medium at rest

$$X=-\frac{dU}{dt}-\frac{d\phi}{dx},$$

$$Y=-\frac{dV}{dt}-\frac{d\phi}{dy},$$

$$Z=-\frac{dW}{dt}-\frac{d\phi}{dz},$$

where U, V, W are the components of the vector potential. If we consider a surface separating two portions of the same dielectric and coated with electricity whose surface-density is σ, we have, since U, V, W are not discontinuous on crossing the surface,

$$l\,\{\dot{\mathfrak{x}}_1-\dot{\mathfrak{x}}_2\}+m\,(\dot{\mathfrak{y}}_1-\dot{\mathfrak{y}}_2)+n\,(\dot{\mathfrak{z}}_1-\dot{\mathfrak{z}}_2)=-\epsilon\,\frac{d}{dt}\left[l\,\frac{d\phi}{dx}+m\,\frac{d\phi}{dy}+n\,\frac{d\phi}{dz}\right]_1^2,$$

where $\left[l\,\frac{d\phi}{dx}+m\,\frac{d\phi}{dy}+n\,\frac{d\phi}{dz}\right]_1^2$ denotes the difference between the values of $l\,\frac{d\phi}{dx}+m\,\frac{d\phi}{dy}+n\,\frac{d\phi}{dz}$ on the two sides of the surface.

But
$$\left[l\,\frac{d\phi}{dx}+m\,\frac{d\phi}{dy}+n\,\frac{d\phi}{dz}\right]_1^2=-\frac{1}{1+4\pi\epsilon}\,\sigma,$$

so that
$$l\,(\dot{\mathfrak{x}}_1-\dot{\mathfrak{x}}_2)+m\,(\dot{\mathfrak{y}}_1-\dot{\mathfrak{y}}_2)+n\,(\dot{\mathfrak{z}}_1-\dot{\mathfrak{z}}_2)=\frac{\epsilon}{1+4\pi\epsilon}\,\frac{d\sigma}{dt},$$

and so cannot vanish if the surface-density of the electricity changes;

thus Helmholtz's equation seems to be inconsistent with the principle that the change in the quantity of free electricity is caused by conduction currents. In the case above considered, Maxwell's equations lead to no difficulty; it does not follow, however, that Maxwell's assumption that the total current behaves like the flow of an incompressible fluid is absolutely necessary. We shall consider later on the differences which the abandonment of this assumption will make in the theory.

We shall now go on to consider Helmholtz's equations and compare them with the corresponding ones in Maxwell's theory.

The quantities U, V, W are given by equation of the form

$$\mathrm{U}=\tfrac{1}{2}(1-k)\frac{d\psi}{dx}+\iiint\frac{u}{r}d\xi\,d\eta\,d\zeta,$$

where k is the constant which we mentioned before as occurring in Helmholtz's theory, and

$$\psi=-\frac{1}{2\pi}\iiint\frac{d\phi}{dt}\frac{1}{r}\,d\xi\,d\eta\,d\zeta,$$

where ϕ is the electrostatic potential; it follows from these equations that

$$\frac{d\mathrm{U}}{dx}+\frac{d\mathrm{V}}{dy}+\frac{d\mathrm{W}}{dz}=-k\frac{d\phi}{dt}.$$

The corresponding equation in Maxwell's theory is

$$\frac{d\mathrm{U}}{dx}+\frac{d\mathrm{V}}{dy}+\frac{d\mathrm{W}}{dz}=0,$$

so that these equations coincide if $k=0$. We can see from the value of χ given on page 116 that, on Helmholtz's theory, this quantity would also vanish, whatever be the value of k, if the *total* current behaved like the flow of an incompressible fluid.

If α, β, γ are the components of the magnetic force, then on Helmholtz's theory

$$\frac{d\gamma}{dy}-\frac{d\beta}{dz}=\mathrm{A}\left\{\frac{d^2\phi}{dt\,dx}-4\pi u\right\},$$

$$\frac{d\alpha}{dz}-\frac{d\gamma}{dx}=\mathrm{A}\left\{\frac{d^2\phi}{dt\,dy}-4\pi v\right\},$$

$$\frac{d\beta}{dx}-\frac{d\alpha}{dy}=\mathrm{A}\left\{\frac{d^2\phi}{dt\,dz}-4\pi w\right\},$$

where A is a quantity depending on the unit of current adopted, and is such that the force between two parallel elements of currents at right angles to the line joining them is

$$\tfrac{1}{2}\frac{\mathrm{A}^2}{r^2}i\,j\,ds\,ds',$$

where r is the distance between the elements, $i\,j$ the current through them, and $ds\ ds'$ their lengths; the corresponding equations on Maxwell's theory are

$$\frac{d\gamma}{dy}-\frac{d\beta}{dz}=4\pi u,$$

with similar equations for v and w.

If λ, μ, ν are the intensities of magnetisation, ϑ the coefficient of induced magnetisation, the equations satisfied by the components of the dielectric and magnetic polarisation are of the type

$$\nabla^2\mathfrak{x}=\frac{4\pi\epsilon\,(1+4\pi\vartheta)}{(1+4\pi\epsilon_0)\,(1+4\pi\vartheta_0)}A^2\frac{d^2\mathfrak{x}}{dt^2}+\left\{1-\frac{(1+4\pi\vartheta)\,(1+4\pi\epsilon)}{k}\right\}\frac{d}{dx}\left\{\frac{d\mathfrak{x}}{dx}+\frac{d\mathfrak{y}}{dy}+\frac{d\mathfrak{z}}{dz}\right\},$$

$$\nabla^2\lambda=\frac{4\pi\epsilon\,(1+4\pi\vartheta)}{(1+4\pi\epsilon_0)\,(1+4\pi\vartheta_0)}A^2\frac{d^2\lambda}{dt^2},$$

where ϵ_0 and ϑ_0 are the values of ϵ and ϑ for air.

These equations show that the dielectric and magnetic polarisations are propagated by waves. For the dielectric polarisation longitudinal waves are propagated with the velocity

$$\frac{1}{A}\left\{\frac{(1+4\pi\epsilon)\,(1+4\pi\epsilon_0)\,(1+4\pi\vartheta_0)}{4\pi\epsilon k}\right\}^{\frac{1}{2}}.$$

Transverse waves are propagated with the velocity

$$\frac{1}{A}\sqrt{\frac{(1+4\pi\epsilon_0)\,(1+4\pi\vartheta_0)}{4\pi\epsilon\,(1+4\pi\vartheta)}}.$$

Longitudinal waves of magnetic disturbances are propagated with an infinite velocity, and traverse ones with the same velocity as the transverse waves of dielectric polarisation. The electrostatic potential is propagated with the velocity $1/A\sqrt{k}$. In Maxwell's theory the corresponding equations are

$$\nabla^2 x=\mu K\frac{d^2x}{dt^2},$$

$$\nabla^2\lambda=\mu K\frac{d^2\lambda}{dt^2},$$

where μ is the magnetic permeability and K the specific inductive capacity, so that for both dielectric and magnetic polarisation the velocity of the longitudinal wave is infinite, while the velocity of the transverse wave is $1/\sqrt{\mu K}$. The velocity of propagation of the electrostatic potential is infinite. If in Helmholtz's theory we put $k=0$, $\vartheta_0=0$, $\epsilon/\epsilon_0=K$, while both ϵ and ϵ_0 are infinite, we see that the results of his theory will in this respect agree with Maxwell's.

Though in Maxwell's theory the velocity of propagation of the electrostatic potential is infinite, and in Helmholtz's theory $1/A\sqrt{k}$, the electromotive force at a point, and consequently the dielectric polarisation, does not travel with an infinite velocity in Maxwell's theory, or with the velocity $1/A\sqrt{k}$ in Helmholtz's. We can see the reason of this more easily from Maxwell's theory, as the equations are simpler.

Using the notation of that theory, viz., f, g, h, for the components of the electric displacement, F, G, H for the components of the vector potential, and ϕ for the electrostatic potential, then in a dielectric the equations are

$$\frac{4\pi}{K}f=-\frac{dF}{dt}-\frac{d\phi}{dx}$$

$$\frac{4\pi}{K}\frac{df}{dt} = -\frac{d^2F}{dt^2} - \frac{d^2\phi}{dx\,dt};$$

but, since

$$4\pi\mu\frac{df}{dt} = -\nabla^2 F,$$

we see that

$$\frac{1}{\mu K}\nabla^2 F = \frac{d^2F}{dt^2} + \frac{d^2\phi}{dx\,dt}.$$

Now, since $\nabla^2\phi = 0$, a particular solution of this differential equation will be

$$\frac{dF}{dt} + \frac{d\phi}{dx} = 0,$$

while the general solution will be the sum of this solution and the general solution of

$$\frac{1}{\mu K}\nabla^2 F = \frac{d^2F}{dt^2}.$$

The particular solution is propagated at the same rate as ϕ, while the other part of the solution represents a wave travelling with the velocity $1/\sqrt{\mu K}$. Since the part of the solution which travels at an infinite rate satisfies the equation

$$\frac{dF}{dt} + \frac{d\phi}{dx} = 0$$

or

$$f = 0,$$

we see that the electromotive force due to the change in the vector potential just balances the electrostatic electromotive force, so that until the part of the vector potential which travels at the rate $1/\sqrt{\mu K}$ comes up the resultant electromotive force vanishes. This explains how the electromotive force on Maxwell's theory travels at a different rate from the potential, and a similar explanation will apply to Helmholtz's theory. Helmholtz's equations for a conductor are

$$\sigma\nabla^2 u = (1+4\pi\vartheta)\,4\pi A^2\frac{du}{dt} - \frac{d}{dx}\left\{\nabla^2\phi + (1+4\pi\vartheta-k)\,A^2\frac{d^2\phi}{dt^2}\right\}$$

where σ is the specific resistance of the conductor; on Maxwell's theory the equations are

$$\sigma\nabla^2 u = 4\pi\mu\frac{du}{dt},$$

These equations differ by terms involving the unknown constant k; but v. Helmholtz's[1] investigations on the motion of electricity along thin conducting wires show that there is not much hope of distinguishing between the theories by experiments on conductors. We have seen that we can make certain equations which occur in Helmholtz's theory coincide with the corresponding ones in Maxwell's by giving particular values to certain constants. The difference in Helmholtz's and Maxwell's views as to the continuity of the currents is too serious to let us expect that we should ever get a complete agreement between the

[1] *Ueber die Bewegungsgleichungen der Elektricität für ruhende leitende Körper. Gesammelte Werke*, vol. i. p. 603.

theories; and, in fact, make as many assumptions about the constants as we may, there are still differences between the theories.

In order to get as general a theory of these dielectric currents as possible, we shall investigate the consequences of assuming merely that these currents are proportional to the rate of change of the electromotive force, and write dielectric current$=\eta$ (rate of change of the electromotive force), where η is a constant which for the present is left indeterminate; In Maxwell's theory $\eta=\mathrm{K}/4\pi$, where K is the specific inductive capacity of the dielectric; in Helmholtz's theory, η is also proportional to the specific inductive capacity. We shall denote the components of the dielectric currents by the symbols $\dot{f}, \dot{g}, \dot{h}$; the components of the conduction current by p, q, r, and the components of the total current by u, v, w, so that

$$u=p+\dot{f}.$$

Let us put

$$\frac{du}{dx}+\frac{dv}{dy}+\frac{dw}{dz}=\mathrm{P},$$

$$l\,(u_1-u_2)+m\,(v_1-v_2)+n\,(w_1-w_2)=\Sigma\,;$$

on Maxwell's theory P and Σ are each zero.

If F, G, H are the components of the vector potential, then by v. Helmholtz's investigation of the most general expression possible for these quantities consistent with the condition that the forces between closed circuits should agree with those given by Ampère's laws,

$$\mathrm{F}=\tfrac{1}{2}\,(1-k)\,\frac{d\psi}{dx}+\mu\iiint\frac{u}{r}\,d\xi\,d\eta\,d\zeta,$$

with similar expressions for G and H, where k is a constant and

$$\psi=\iiint\mu\left(u\,\frac{dr}{d\xi}+v\,\frac{dr}{d\eta}+w\,\frac{dr}{d\zeta}\right)d\xi\,d\eta\,d\zeta.$$

Transforming this expression we see, using the same notation as before, that

$$\begin{aligned}\psi=&\iint r\mu\,\{l\,(u_1-u_2)+m\,(v_1-v_2)+n\,(w_1-w_2)\}\,d\mathrm{S}\\&\qquad-\iiint r\mu\left(\frac{du}{d\xi}+\frac{dv}{d\eta}+\frac{dw}{d\zeta}\right)d\xi\,d\eta\,d\zeta\\=&\iint\mu r\,\Sigma\,d\,\mathrm{S}-\iiint\mu r\,\mathrm{P}\,d\xi\,d\eta\,d\zeta,\end{aligned}$$

where $d\mathrm{S}$ is an element of a surface at which there is discontinuity in u, v, w.

Let us now consider the equations which hold in a perfectly insulating dielectric.

The rate of change of the x component of the electromotive force in a medium at rest

$$=-\frac{d^2\mathrm{F}}{dt^2}-\frac{d^2\phi}{dt\,dx},$$

where ϕ is the electrostatic potential; it also equals $\dot{f}/\eta$, so that

$$\frac{\dot{f}}{\eta}=-\frac{d^2\mathrm{F}}{dt^2}-\frac{d^2\phi}{dt\,dx}.$$

Since in this case there is no conduction current $u = \dot{f}$, and the preceding equation for F shows that

$$\nabla^2 F = \tfrac{1}{2}(1-k)\frac{d}{dx}\nabla^2\psi - 4\pi\mu\dot{f}.$$

substituting for $\dot{f}$

$$\nabla^2 F - \tfrac{1}{2}(1-k)\frac{d}{dx}\nabla^2\psi = 4\pi\eta\left\{\frac{d^2F}{dt^2} + \frac{d^2\phi}{dx\,dt}\right\}.$$

if $\dfrac{dF}{dx} + \dfrac{dG}{dy} + \dfrac{dH}{dz} = \chi$, we get, by differentiating this expression, with regard to x and the corresponding equations for G and H with regard to y and z respectively, and adding

$$\nabla^2\chi - \tfrac{1}{2}(1-k)\,\nabla^4\psi = 4\pi\eta\mu\left\{\frac{d^2}{dt^2}\chi + \frac{d}{dt}\nabla^2\phi\right\}.$$

Now, as the dielectric is a perfect insulator, there are no conduction currents, so that the density of the free electricity remains constant, and therefore

$$\frac{d}{dt}\nabla^2\phi = 0.$$

From the expression for ψ we see that

$$\begin{aligned}\nabla^4\psi &= +\,8\pi P \\ &= -\,8\pi\eta\mu\left(\frac{d^2\chi}{dt^2} + \frac{d}{dt}\nabla^2\phi\right) \\ &= -\,8\pi\eta\mu\frac{d^2\chi}{dt^2}.\end{aligned}$$

Substituting this value of $\nabla^4\psi$ in the equation for χ, we get

$$\nabla^2\chi = 4\pi\eta\mu k\frac{d^2\chi}{dt^2},$$

which represents the propagation of a normal wave with the velocity

$$1/\sqrt{4\pi\eta k}.$$

The transverse wave is propagated with the velocity $1/\sqrt{4\pi\eta\mu}$, so that if the view that light consists of electric or magnetic disturbances be correct, since experiment shows that this velocity is very nearly equal to $1/\sqrt{K\mu}$, we must have $4\pi\eta = K$ or $\eta = K/4\pi$, which is Maxwell's theory. So that if we assume that light is an electric phenomenon, then in those media in which its velocity $= 1/\sqrt{\mu K}$ Maxwell's theory that the electric currents flow like an incompressible fluid must be true.

If α, β, γ are the components of the magnetic force, then, since

$$F = \tfrac{1}{2}(1-k)\frac{d\psi}{dx} + \mu\iiint\frac{u}{r}\,d\xi\,d\eta\,d\zeta,$$

we see from Ampère's formula for the magnetic force due to a circuit that

$$\mu\alpha = \frac{dH}{dy} - \frac{dG}{dz} - \mu\frac{dV}{dx},$$

where V is the magnetic potential due to the magnetism in the field both permanent and induced. From these equations we get

$$\mu\left\{\frac{d\alpha}{dy}-\frac{d\beta}{dx}\right\}=\nabla^2 H-\frac{d}{dz}\left(\frac{dF}{dx}+\frac{dG}{dy}+\frac{dH}{dz}\right)$$

$$=-4\pi\mu w+\frac{d}{dz}\left\{\tfrac{1}{2}(1-k)\nabla^2\psi-\chi\right\}$$

instead of the equation

$$\frac{d\alpha}{dy}-\frac{d\beta}{dx}=-4\pi w.$$

We have been obliged to introduce another assumption here, viz., that the magnetic force due to an element of current is given by Ampère's expression.

We could not assume Maxwell's way of connecting currents with magnetic force, viz. that the total current flowing through any closed curve is equal to the line integral of the magnetic force round the curve, for the result can only be true when the currents flow like an incompressible fluid.

Let us now go on to consider the force acting on the medium conveying the current.

If we consider a continuous distribution of currents, the kinetic energy

$$=\tfrac{1}{2}\iiint (Fu+Gv+Hw)\,dx\,dy\,dz.$$

If we derive the force parallel to x by the variation of the energy in the usual way we find, just as in Helmholtz's paper,[1] that the force parallel to x

$$=\left\{v\left(\frac{dG}{dx}-\frac{dU}{dy}\right)+w\left(\frac{dH}{dx}-\frac{dU}{dz}\right)-F\left(\frac{du}{dx}+\frac{dv}{dy}+\frac{dw}{dz}\right)\right\},$$

or with our notation

$$=v\left\{\frac{dG}{dx}-\frac{dU}{dy}\right\}+w\left\{\frac{dH}{dx}-\frac{dU}{dz}\right\}-FP,$$

and that on any surface where there is a discontinuity in the values of u, v, w there is a force equal per unit of area to

$$F\{l(u_1-u_2)+m(v_1-v_2)+n(w_1-w_2)\}$$

or $F\Sigma$.

In the same paper it is shown that it follows from the principle of the Conservation of Energy that the force exerted by a distribution of currents equals the force given by Ampère's expression along with a force at the point $\xi\eta\zeta$ whose component parallel to the axis of x equals

$$\iiint\left(\frac{du}{dx}+\frac{dv}{dy}+\frac{dw}{dz}\right)\frac{x-\xi}{r^4}\Big(u'(x-\xi)+v'(y-\eta)+w'(z-\zeta)\Big)dx\,dy\,dz$$

$$+\iint\left\{l(u_1-u_2)+m(v_1-v_2)+n(w_1-w_2)\right\}\frac{x-\xi}{r^2}\Big(u'(x-\xi)$$

$$+v'(y-\eta)+w'(z-\zeta)\Big)dS;$$

[1] *Die elektrodynamischen Kräfte in bewegten Leitern*, Crelle, lxxviii. p. 298. 1874, or *Gesammelte Werke*, vol. i. p. 733.

or with our notation

$$\iiint \mathrm{P}\,\frac{x-\xi}{r^4}\Big(u'\,(x-\xi)+v'\,(y-\eta)+w'\,(z-\zeta)\Big)\,dx\,dy\,dz$$

$$+\iint \Sigma\,\frac{x-\xi}{r^4}\Big(u'\,(x-\xi)+v'\,(y-\eta)+w'\,(z-\zeta)\Big)\,d\mathrm{S},$$

where u', v', w' are the components of the current at the point $\xi\,\eta\,\zeta$; so that in addition to Ampère's forces we have additional forces wherever P and Σ have finite values. From the above expressions we see that any element where P has a finite value exerts a repulsive force equal per unit of volume to

$$\frac{\mathrm{P}}{r}\,i\cos\theta,$$

tending from the element; where r is the distance of the element from the point at which the force is reckoned, i the intensity of the current at this point, and θ the angle between the direction of the current and r. Any element of surface where Σ has a finite value exerts a repulsive force equal per unit of surface to

$$\frac{\Sigma}{r}\,i\cos\theta,$$

where the notation is the same as before. Of course none of these forces exist in Maxwell's theory. They could be most easily detected in cases where the part of the forces given by Ampère's theory vanishes as it would for the case of an endless solenoid. In this case, though the Ampèrian forces vanish, the forces due to the discontinuity in the current do not, so that if the endless solenoid were to move under the action of external currents it would denote the existence of discontinuity in the current. An experiment of this kind has been made by Schiller; we shall discuss the results of it later.

To sum up, the differences between the most general theory which takes into account the action of the dielectric, and Maxwell's, are—

1. The existence of a normal wave in the general theory, but not in Maxwell's.

2. The difference in the velocity of propagation of the transverse wave.

3. The difference in the relation between electric currents and magnetic force.

4. The forces which arise from discontinuity in the currents.

The Experimental Evidence as to the Truth of the various Theories.

The theories we have considered may be divided into two great classes, according as they do or do not take into account the action of the dielectric surrounding the various conductors in the field. The first thing, therefore, that we have to do is to see whether experiment throws any light on this point.

When a dielectric is in an electric field it experiences a change in its structure; this is rendered evident by the alterations in its volume and elasticity observed by Quincke, by the change in its optical properties

observed by Kerr, and also by the fracture of the dielectric when the field is made sufficiently intense. So that whenever an electromotive force acts on a dielectric it produces a change in its structure which we shall always speak of as polarisation. This, strictly speaking, has only been directly proved for electromotive forces produced by charges of statical electricity; but, unless we are prepared to say that the electromotive force due to statical electricity is in some way different from that due to a changing current, we must admit that when an electromotive force of the latter kind acts on a dielectric it polarises it. And we are not without experimental evidence that the electromotive force due to variations in the vector potential does produce some of the effects of the electromotive force due to a charge of statical electricity. Rowland's experiments have shown that a moving electrified body will set a magnet placed near to it in motion. It follows from this, by dynamical principles, that if we have the charged body initially at rest and move the magnet it will, if no other forces act upon it, be set in motion; so that in this case there is an electromotive force due to the motion of the magnet, *i.e.*, the variation in the vector potential produces the same effect on the electrified body as the electromotive force due to a charge of statical electricity. For this reason we shall suppose that the electromotive force due to the variation in the vector potential always produces effects on a dielectric on which it acts of the same type as those which have been observed to arise from the action of an electromotive force due to a charge of statical electricity.

Let us now consider a magnet surrounded by a dielectric. If we set the magnet in motion, we produce an electromotive force which polarises the dielectric. Let us, to fix our ideas, consider an element of the dielectric and the magnet. When the magnet moves it polarises the dielectric; it follows from dynamical principles (an extension of the principle of action and reaction),[1] that if the polarisation of the dielectric be altered, the magnet will move, so that a change in the polarisation of a dielectric produces a magnetic force.

Again, let us instead of the magnet consider a coil of wire conveying a current. A change in the rate of flow of the current produces a change in the polarisation of the dielectric; it follows that a change in the rate of change of the polarisation of the dielectric will produce a change in the current, *i.e.*, will produce an electromotive force.

It follows too, from dynamical principles, that as the change in the polarisation of an element of the dielectric due to the change in the current depends on the distance of the element from the current, there must be a force between the current and the element when the polarisation of the latter is changing. Thus we see that a change in the polarisation of the dielectric must produce all the effects of an ordinary conduction current, so that it is only absolutely necessary to consider how the experimental evidence affects those theories which take the action of the dielectric into account. As, however, the experiments which have been made are few in number, and are all concerned with interesting points, we shall consider them in their relation to all the theories, and not only to those which take the dielectric into account.

[1] See a paper by the author of this report 'On some Applications of Dynamical Principles to Physical Phenomena,' *Phil. Trans.*, 1885.

Schiller's Experiments.

The first experiment which we shall discuss is one made by Schiller, and described by him in Poggendorf's Annalen, vol. clix. pp. 456, 537; it was intended to test the potential theories of Neumann and Helmholtz. We saw that, according to these theories, in an unclosed circuit there are, in addition to the forces due to the elements of current, and which are expressed by Ampère's law, forces arising from the discontinuity of the currents at the ends of the circuit. If we have an end of a circuit where the current stops, and the electricity accumulates at the rate de/dt, it will exert on an element of current of length ds traversed by a current of intensity i a force tending to the end and equal to

$$A^2 ids \frac{de}{dt} \frac{\cos\theta}{r}$$

where θ is the angle between the element of current and the radius drawn to it from the end. If we calculate from this expression the couple produced by an end on an endless solenoid, or on what is practically the same thing, a ring magnet, we shall find that the couple tending to turn the ring about an axis in its own place will not vanish, while the couple arising from the forces given by Ampère's law will. Thus if the ring rotates, as it should according to the potential theory, it must be from the action of the end.

In Schiller's experiment the end of the current was the end of wire connected with a Holtz machine. This was placed near to a ring magnet which was suspended by a long cocoon fibre; the magnet was protected from electrostatic influences by being enclosed in a metal box connected with the earth. Schiller determined the intensity of magnetisation of the ring magnet and the quantity of electricity passing through the point, and he calculated that if the potential theory were true, he ought to get a deflection of the magnet of about 27 scale divisions, instead of which there was no perceptible deflection.

This experiment shows conclusively that the potential theory is wrong if we neglect altogether the action of the dielectric, and assume the current to stop at the end of the wire. If, however, we take the dielectric into account, the experiment tells us nothing as to whether Maxwell's theory or the more general one is true; for since the current from the Holtz machine is steady, as much electricity flows out from the end of the wires as arrives there; and thus there is really no discontinuity in the current, the only difference being that before reaching the end the current is flowing through copper and after passing it through air. The condition of things at the end of the wire remains steady, and thus the quantities which we denoted by P and Σ vanish.

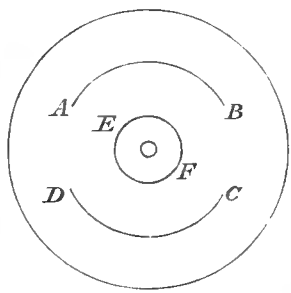
The experiment might, however, be modified so as to be capable of distinguishing between the theories which take the dielectric into account. For suppose that, instead of letting the electricity escape through the point, we never let the potential at the end of the wire get so high as to allow the electricity to escape; then if the wire is initially uncharged, the condition at the end will be changing whilst the wire is charging up, and thus Σ will have a finite value; so that if the magnet were sufficiently delicate and remained undeflected, whilst the point was surrounded by dielectrics of all kinds, it would show that Maxwell's theory is correct.

I have calculated the effect which would be produced on Schiller's

suspended magnet, and find that it is too small to be observed; as, however, the time of charging up the wire will be very small compared with the time of vibration of the magnet, the effect will be of the nature of an impulse, so that in this case there will be considerable advantage in having the moment of inertia of the suspended magnet small; while, as Schiller arranged the experiment, there was no such advantage, as the thing expected was a steady deflection. Thus if the ring magnet were retained it would be desirable to make the opening of it as small as possible, retaining the same cross action. I think the arrangement could be made sensitive enough to be deflected if the value of Σ were any considerable fraction of the rate of increase of the electricity at the end of the wire.

There is another way in which the continuity or discontinuity of the current might be tested, and which might perhaps be more delicate than the last. We saw on p. 141 that at any point of a current at which Σ had a finite value the mechanical force on the element is not at right angles to the element. In addition to the ordinary force at right angles to the element, there is a force in the direction of the vector potential equal in magnitude to the product of the values of the vector potential and Σ.

The existence of this force could be tested by an arrangement of the following kind:—



AB and CD are light movable segments of the same circle, having balls covered with paraffin A, B, C, D fastened to their ends. These segments are connected with a very light framework which can rotate about an axis perpendicular to the plane of the segments; the segments touch at their middle points contact-pieces which are connected with a Holtz machine. EF is the section of an electromagnet concentric with AB and CD; the whole is surrounded with a metal cylinder to screen it from external electric influences. When a current is passing through the electromagnet it produces a vector potential, whose direction is at right angles to the radius from O, the centre of the electromagnet perpendicular to its axis. Thus if Σ exists there will be a couple tending to twist the system AB, CD about its axis, but if Σ exists at all it will be when the electrical condition of the balls A, B, C, D is changing, so that unless the currents are continuous we should expect the system to rotate when the balls are being charged up. I have calculated that the system might easily be made sensitive enough to be sensibly deflected on charging or discharging, provided Σ is an appreciable fraction of the rate of change of the surface-density of the electricity on the balls.

Schiller's Second Experiment.[1]

Schiller has made another experiment, which shows that Ampère's theory fails for unclosed circuits. The first form of the experiment consisted in having a solenoid placed over a condenser one of whose plates could rotate about a vertical axis coinciding with the axis of the solenoid. One end of the solenoid was connected to one plate of the condenser and the other end to the other plate. When the solenoid is connected to a

[1] Pogg. *Ann.*, clix. p. 456; clx. p. 333.

battery the condenser will charge up and there will be radial currents of electricity in the plates; the current passing through the solenoid will produce a magnetic force which will, if Ampère's theory be true, act on the radial currents in the plate of the condenser and set it in rotation. Schiller found that this effect was too small to be observed, so he modified the experiment in the following way. Let us suppose that we have the two plates of the condenser rigidly attached to their axis and placed in a field symmetrical about its axis, in which the vertical component of the magnetic force is not uniform. Then if a current be sent through the upper plate, down through the axis, and out at the lower plate, the couple tending to twist the lower plate will not be equal and opposite to that tending to twist the upper one, as the magnetic force is not equal at the two plates, and thus the condenser will be set in rotation. Conversely, if the condenser be set in rotation in the magnetic field, and two electrodes of a galvanometer be connected with its axis, then if Ampère's theory be true there will be an electromotive force acting round the galvanometer circuit, which will produce a current, and this current could be much more easily detected than the rotation in the first form of the experiment. Schiller calculated the deflection which he ought to get if Ampère's theory were true, and found that he could easily detect it if it existed; as he was not able to see any deflection, we must conclude that Ampère's theory is not the true one.

It is easy to see that, according to the potential theory, there would be no current in the galvanometer; for, as everything is symmetrical about the axis, the potential is not altered by the rotation. The following calculation will show that, according to the dielectric theories, there should be no current through the galvanometer.

For if a, b, c are the components of magnetic induction, F, G, H those of the vector potential, X, Y, Z those of the electromotive force, then

$$\mathrm{X} = c\frac{dy}{dt} - b\frac{dz}{dt} - \frac{d}{dx}\left\{\mathrm{F}\frac{dx}{dt} + \mathrm{G}\frac{dy}{dt} + \mathrm{H}\frac{dz}{dt}\right\},$$

$$\mathrm{Y} = a\frac{dz}{dt} - c\frac{dx}{dt} - \frac{d}{dy}\left\{\mathrm{F}\frac{dx}{dt} + \mathrm{G}\frac{dy}{dt} + \mathrm{H}\frac{dz}{dt}\right\}.$$

Suppose the condenser is rotating with an angular velocity ω about the axis of Z; then the E.M.F. arising from one plate is, if R be its radius,

$$\omega\int_0^{\mathrm{R}} cr\,dr - \left(\mathrm{F}\frac{dx}{dt} + \mathrm{G}\frac{dy}{dt}\right),$$

Now
$$\mathrm{F}\frac{dx}{dt} + \mathrm{G}\frac{dy}{dt} = \omega\mathrm{R}\Theta,$$

where Θ is the component of the vector potential along the direction of motion of a point on the circumference of the plate of the condenser.

But the line integral of the vector potential round any curve equals the number of lines of magnetic force passing through it, so that, since the field is symmetrical,

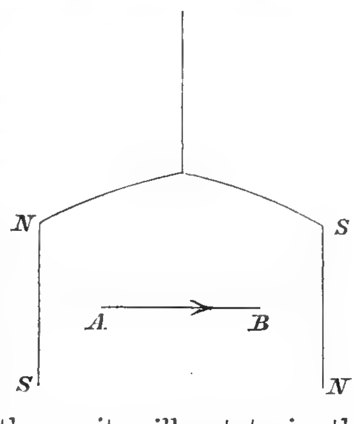
$$2\pi\int_0^{\mathrm{R}} cr\,dr = 2\pi\mathrm{R}\Theta.$$

From this equation we see that the E.M.F. due to the rotation vanishes for each plate, so that, according to this theory, there should be no current through the galvanometer.

This experiment of Schiller shows that both Grassmann's and Clausius' theories must be wrong, as well as Ampère's and Korteweg's, for we can easily see that they would make the disc rotate in the way in which Schiller first tried the experiment, and if this were so, it follows from dynamical principles that a current must be produced in the second form of the experiment.

This would seem to be the case even if we take into account the currents in the dielectric, unless we suppose that all the circuits are closed, for if all the circuits are closed then the disc will not rotate, as all the theories agree. If the circuits are not closed we may divide the currents in the disc into two parts, one part being of such magnitude as to form with the dielectric currents closed circuits; then the forces on this part and the dielectric will form a system in equilibrium; and there remains the other part of the currents, the action of the magnet on which ought to set the disc in rotation. Taking Schiller's experiments together, we may say that they show that the dielectric must be taken into account, and that some form of the potential theory is the only one of the theories we are considering which can give the expression for the forces due to a distribution of currents.

Although these two experiments of Schiller's show that of the theories we have discussed only the dielectric ones can be retained, we shall describe one or two more experiments which have been or could be made to distinguish between the various theories. Clausius' and Grassmann's theories lead to the same expression for the force between two elements of current, so that these theories stand or fall together. Grassmann in his paper[1] describes an experiment which would distinguish between his theory and Ampère's, or, in fact, any other except Clausius' which has ever been published.

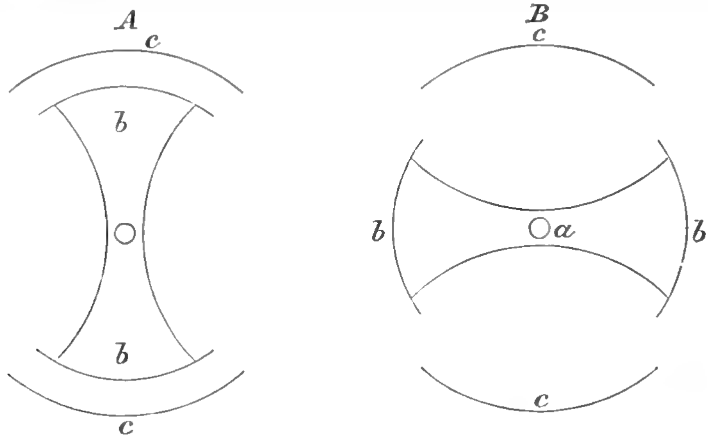


Suppose that NS and SN are two magnets whose north and south poles are denoted by N and S respectively, and that these magnets are fastened together by a rod NS, the system being suspended by a cocoon thread attached to the middle point of NS. Let AB be an unclosed circuit, say a wire joining the plates of a charged condenser; then, according to Grassmann's and Clausius' theories, the system will rotate in such a way that the sense of rotation is related to a vertical line drawn downwards like rotation and translation in a right-handed screw. According to every other theory it will rotate in the opposite direction.

Another experiment has been made by v. Helmholtz,[2] which shows that the potential theory leads to wrong results unless the action of the dielectric is taken into account. *bb* is a rotating conductor, to the ends of which large condenser plates are attached, which, when in rotation, come very near to the similar plates *c*, *c*. The plates *b* and *c* are segments

[1] Pogg., lxiv. 1, 1845. [2] *Wissenschaftliche Abhandlungen*, vol. . 783.

of coaxial cylinders. In v. Helmholtz's experiments bb was rotated between the poles of a powerful electromagnet. The plates c, c were connected with a commutator, which put them to earth when the rotating piece was in the position A, and to the plates of a Kohlrausch condenser when it was in the position B. Now suppose there is a difference of potential between b and c; suppose, for clearness, that b is at a higher potential than c, then when the rotating piece is in the position A the positive electricity goes to earth, and the negative is left to go to the Kohlrausch condenser, when the rotating piece gets to the position B. The change in this condenser was measured by a quadrant electrometer. v. Helmholtz found that the needle of the electrometer was deflected when the piece bb was rotating. Since everything is symmetrical about the axis of rotation, there would be no difference of potential between the



plates b and c, according to the potential law, if we neglect the action of the dielectric. According to Ampère's law there will be a difference of potential between b and c equal to $\Theta a\omega$, where a is the radius of the rotating piece, ω its angular velocity, and Θ the vector potential along the direction of motion of the disc. According to the dielectric theory there will also be the same difference of potential between b and c if we suppose that there is no discontinuity in the motion. We shall suppose that, instead of the velocity changing abruptly from ωa to zero as we pass from the rotating conductor to the dielectric, there is a layer of the dielectric next to the conductor in which the change of velocity is very rapid, one side of the layer moving with the velocity ωa, the other side being at rest. Then, using the same notation as before, we have—

$$X = c\frac{dy}{dt} - b\frac{dz}{dt} - \frac{d}{dx}\left\{F\frac{dx}{dt} + G\frac{dy}{dt} + H\frac{dz}{dt}\right\},$$

$$Y = a\frac{dz}{dt} - c\frac{dx}{dt} - \frac{d}{dy}\left\{F\frac{dx}{dt} + G\frac{dy}{dt} + H\frac{dz}{dt}\right\}.$$

Integrating across the thin layer of the dielectric, in which the velocity is changing rapidly, we see that the difference of potential between b and c equals

$$F\frac{dx}{dt} + G\frac{dy}{dt} + H\frac{dz}{dt},$$

where dx/dt, dy/dt, dz/dt are the velocities of a point on the boundary

of the moving conductor. This equals $\Theta a\omega$, the same value as that given by Ampère's theory, so that in this case the two theories lead to identical results, which are in agreement with the result of Helmholtz's experiments.

Rontgen has recently published[1] a preliminary account of some experiments which seem to prove directly that the variations in the dielectric polarisation produce effects analogous to those due to a current.

This completes the account of the experiments which have been made to test the various theories. As the result of them we may say that they show that it is necessary to take into account the action of the dielectric, but they tell us nothing as to whether any special form of the dielectric theory, such as Maxwell's or Helmholtz's, is true or not.

I have described two experiments which would decide whether Maxwell's theory that all circuits are closed is true or not. It seems to me, however, that even if Maxwell's theory be wrong, Helmholtz's is not the only alternative. I have given a sketch of a theory in which I have tried to make as few assumptions as possible; all that I have assumed is that when a dielectric is acted on by a changing electromotive force, it behaves like a conductor conveying a current whose intensity is proportional to the rate of change of the electromotive force. We know from experiment that it produces effects of the same character, and I have assumed as the simplest assumption I could make that for the same dielectric the equivalent current is proportional to the rate of change of the electromotive force, so that equivalent current $= \eta$ (rate of change of electromotive force).

Both Maxwell and Helmholtz assume that η depends only on the specific inductive capacity of the dielectric, but I think it is preferable, until we have more experiments on this point, to look on η as the measure of a new property of a dielectric, and not to assume that it is merely a function of the specific inductive capacity, the only experimental evidence for this being the by no means perfect agreement between the refractive index and the reciprocal of the square root of the specific inductive capacity. To prove Maxwell's theory of closed circuits it would not be sufficient to prove that for one medium, say air, $\eta = \mathrm{K}/4\pi$, for it is quite conceivable that electrical phenomena may be simpler in a dielectric like air, where the electrical behaviour of the ether seems to be but little affected by the presence of the dielectric, than in such a one as glass or other substance possessing a comparatively large specific inductive capacity, when the effect of the ether is seriously modified by the presence of the medium.

Since in the theory I have sketched the values of

$$\frac{du}{dx} + \frac{dv}{dy} + \frac{dw}{dz},$$

and

$$l\,(u_1 - u_2) + m\,(v_1 - v_2) + n\,(w_1 - w_2)$$

are not zero, but arbitrary, inasmuch as they involve η, in order to find the value of the force between two circuits where there is any discontinuity in the currents we shall require to know the value of the quantity k which occurs in v. Helmholtz's theory.

The most pressing need in the theory of electrodynamics seems to

[1] *Phil. Mag.*, May, 1885.

be an experimental investigation of the question of the continuity of these dielectric currents; we have experimental proof that they exist, but we do not know whether Maxwell's assumption that they always form closed circuits with the other currents is true or not. If Maxwell's assumption should turn out to be true, we should have a complete theory of electrical action; if, on the other hand, it should turn out to be wrong, then we should have to go on to determine the quantity k. This quantity is difficult to determine, as its influence on all closed circuits disappears. It influences, as v. Helmholtz has shown, the rate of propagation of the electric potential along conducting wires, and I think we can see that it would influence the time of oscillation of an irregular distribution of electricity over a conducting shell. The easiest way, however, of determining this quantity would seem to be the straightforward one of measuring electrostatically the value of the electromotive force due to a variation in the charge of a condenser; the expression for the vector potential, as we saw on p. 140, involves k, so that if we measure the electromotive force, which is equal to the rate of variation of the vector potential, we shall determine the value of the vector potential, and consequently of k.

APPENDIX I.

Since the Report was written I have had through the kindness of the author an opportunity of seeing the advance proofs of a paper by Professor J. H. Poynting, of Mason's College, Birmingham, 'On the Connexion between Electric Current and the Electric and Magnetic Induction in the Surrounding Medium,' which is about to appear in the 'Philosophical Transactions.'

The views expressed in this paper are rather a new way of looking at Faraday and Maxwell's theory than a new theory of electrodynamic action, as however it brings the action of the dielectric into great prominence it is instructive to consider it.

The paper is largely based on a previous one by the same author on the 'Transference of Energy in the Electromagnetic Field,'[1] it is therefore necessary to give a brief account of this paper.

In it the author shows that the rate of increase of the energy inside any closed surface equals

$$\frac{1}{4\pi}\iint\{l(\mathrm{R}'\beta-\mathrm{Q}'\gamma)+m(\gamma\mathrm{P}'-\alpha\mathrm{R}')+n(\alpha\mathrm{Q}'-\beta\mathrm{P}')\}\,d\mathrm{S},$$

where $d\mathrm{S}$ is an element of surface, l, m, n the direction cosine of the normal to $d\mathrm{S}$, α, β, γ the components of magnetic induction, and P', Q', R' given by the following equations:—

$$\mathrm{P}'=-\frac{d\mathrm{F}}{dt}-\frac{d\psi}{dx},$$

$$\mathrm{Q}'=-\frac{d\mathrm{G}}{dt}-\frac{d\psi}{dy},$$

$$\mathrm{R}'=-\frac{d\mathrm{H}}{dt}-\frac{d\psi}{dz},$$

[1] *Phil. Trans.*, 1884, part ii

where F, G, and H are the components of the vector potential and ψ the electrostatic potential; thus if the medium is at rest P′, Q′, R′ are the components of the electromotive force at the point.

Professor Poynting interprets this equation to mean that the components parallel to the axes of x, y, z of the flow of energy across *each* element of surface are respectively

$$\frac{1}{4\pi}(R'\beta - Q'\gamma),$$

$$\frac{1}{4\pi}(P'\gamma - R'\alpha),$$

$$\frac{1}{4\pi}(Q'\alpha - P'\beta),$$

so that according to this view the energy flows in the direction which is at right angles both to the magnetic and electromotive forces, and in the direction in which a right-handed screw would move if turned round from the positive direction of the electric intensity to the positive direction of the magnetic intensity; the quantity of energy crossing in unit time unit surface at right angles to this direction being

$$\frac{1}{4\pi}\ .\ \text{Electromotive force at the point} \times \text{magnetic force} \times \text{sine of the angle between these forces.}$$

This interpretation of the expression for the variation in the energy seems open to question. In the first place it would seem impossible *à priori* to determine the way in which the energy flows from one part of the field to another by merely differentiating a general expression for the energy in any region with respect to the time, without having any knowledge of the mechanism which produces the phenomena which occur in the electromagnetic field: for although we can by means of Hamilton's or Lagrange's equations deduce from the expression for the energy the forces present in any dynamical system, and therefore the way in which the energy will move, yet for this purpose we require the energy to be expressed in terms of coordinates fixing the system, and it will not do to take any expression which happens to be equal to it. The problem of finding the way in which the energy is transmitted in a system whose mechanism is unknown seems to be an indeterminate one; thus, for example, if the energy inside a closed surface remains constant we cannot unless we know the mechanism of the system tell whether this is because there is no flow of energy either into or out of the surface, or because as much flows in as flows out. The reason for this difference between what we should expect and the result obtained in this paper is not far to seek. Though the increase in the energy inside a closed surface equals

$$\frac{1}{4\pi}\iint\{l\,(R'\beta - Q'\gamma) + \ldots\}\,dS,$$

it does not follow that the components of the flow of energy across *each* element of surface are $(R'\beta - Q'\gamma)/4\pi$, &c., for we can find quantities u, v, w which are of the dimensions of rate of change of energy per unit area, and for which

$$\iint(lu + mv + nw)\,dS = 0.$$

The following values of u, v, w satisfy this condition :—

$$u = \frac{1}{\mu}\left\{ \frac{d^2}{dy\,dt}(\mathrm{FG}) - \frac{d^2}{dz\,dt}(\mathrm{HF}) \right\},$$

$$v = \frac{1}{\mu}\left\{ \frac{d^2}{dz\,dt}(\mathrm{GH}) - \frac{d^2}{dx\,dt}(\mathrm{FG}) \right\},$$

$$w = \frac{1}{\mu}\left\{ \frac{d^2}{dx\,dt}(\mathrm{HF}) - \frac{d^2}{dy\,dt}(\mathrm{GH}) \right\},$$

where μ is the magnetic permeability and F, G, H are the components of the vector potential, or if ψ be the electrostatic potential

$$u = \frac{d}{dy}\left\{ \frac{d\psi}{dz}\mathrm{H} \right\} - \frac{d}{dz}\left\{ \frac{d\psi}{dy}\mathrm{G} \right\},$$

$$v = \frac{d}{dz}\left\{ \frac{d\psi}{dx}\mathrm{F} \right\} - \frac{d}{dx}\left\{ \frac{d\psi}{dz}\mathrm{H} \right\},$$

$$w = \frac{d}{dx}\left\{ \frac{d\psi}{dy}\mathrm{G} \right\} - \frac{d}{dy}\left\{ \frac{d\psi}{dx}\mathrm{F} \right\},$$

If the values of u, v, w which satisfy these conditions be denoted by the (u_1, v_1, w_1), (u_2, v_2, w_2) . . . then the flow across any element of surface might have for its x component—

$$\frac{1}{4\mu}(\mathrm{R}'\beta - \mathrm{Q}'\gamma) + \lambda_1 u_1 + \lambda_2 u_2 + \lambda_3 u_3 + \ . \ . \ .$$

where $\lambda_1, \lambda_2, \lambda_3$ are arbitrary constants, thus we see that the components of the flow of energy, instead of being uniquely determined by this process are really left quite indeterminate by it. Though this is so, it is very instructive to follow Professor Poynting's description of the way in which the energy flows in some special cases; we shall select a very simple one, the case of a current flowing along a straight wire. Here the lines of electromotive force are straight lines parallel to the wire, the lines of magnetic force are circles with their centres on the wire, and their planes at right angles to it. Then, since according to the view expressed in the paper, the energy moves at right angles both to the electric and magnetic forces, it must in this case move radially inwards to the wire where it is converted into heat. The energy, instead of being supposed to be transmitted through the wire, is regarded as transmitted by the dielectric; and though we may not regard the exact law of flow of the energy as established, still it is very important that this view should be brought into prominence. Another important point brought prominently forward in this paper is the view that magnetic force is always the sign of transference of energy, according to Professor Poynting; indeed, there must be transference of energy from one part of the field to another to give rise to magnetic force. Thus, according to his view, no magnetic force would be exerted by the discharge of a leaky condenser, because in this case he considers the energy to be confined to the space between the plates of the condenser and to be converted into heat where it stands. If the plates were connected by a metallic wire, the energy could flow out and be converted into heat in the wire and this motion of energy would give rise to magnetic forces, so that magnetic

forces would be produced by the discharge of a condenser in this way, but not by leakage. In this case the theory differs from Maxwell's, as according to that theory the alteration in the electromotive force would produce magnetic forces in either case.

In Professor Poynting's second paper, which we have already mentioned, the fundamental principles of electrodynamics are described as the results of the motion of the tubes of electromotive and magnetic force. Maxwell develops electrodynamics from the principles :—

1st. That the total electromotive force round any closed curve is equal to the rate of decrease of the total magnetic induction through the curve.

2nd. The line integral of the magnetic force round any closed curve is equal to 4π times the current through the curve.

Professor Poynting restates these principles in the following way :—

1. 'Whenever electromotive force is produced by change in the magnetic field, or by motion of matter through the field, the E.M.F. per unit length is equal to the number of tubes of magnetic induction cutting or cut by the unit length per second, the E.M.F tending to produce induction in the direction in which a right-handed screw would move if turned round from the direction of motion relatively to the tubes towards the direction of the magnetic induction.'

The second principle he states in the following way :—

'Whenever magnetomotive force is produced by change in the electric field, or by motion of matter through the field, the magnetomotive force per unit length is equal to 4π times the number of tubes of electric induction cutting or cut by unit length per second, the magnetomotive force tending to produce induction in the direction in which a right-handed screw would move if turned round from the direction of the electric induction towards the direction of motion of the unit length relatively to the tubes of induction.'

By magnetomotive force is meant the line integral of the magnetomotive force round a tube of induction. This statement includes the more special one that the line integral of the magnetic force round any closed curve is equal to 4π times the number of tubes passing in or out through the curve per second.

The development of these principles leads to equations which are practically the same as those obtained by Maxwell, the chief difference being that the quantity corresponding to Maxwell's J is no longer arbitrary or rather redundant.

Professor Poynting also introduces into his equations the time integrals of the components of the magnetic force as fundamental quantities, and regards the components of the magnetic as the differential coefficients of these quantities with regard to the time. This method of representing magnetic force was also used by Professor Fitzgerald in his paper on the Electromagnetic Theory of the Reflection and Refraction of Light.[1] It has the advantage of calling attention to the dynamic character of magnetic phenomena. In Professor Poynting's paper some of the applications of his method of regarding electrical phenomena are worked out with great detail for some of the simpler cases.

[1] *Phil. Trans.*, 1880, part ii.

APPENDIX II.

ON THE STRESS IN THE DIELECTRIC.

In the preceding Report we have had so frequently to refer to the action of the dielectric that it may be convenient to give a very brief account of the work which has been done on the stresses which are supposed to exist in it. We shall confine ourselves to the work which has been done on the stresses in the electrostatic field; those existing in the electromagnetic field are of a similar nature, so that any remark applying to one will also apply to the other. The idea of explaining the forces in the electrostatic field by means of stresses in the dielectric seems to be due to Faraday, who describes [1] the stress in the medium by saying that the lines of force tend to contract and also to repel one another. The magnitude and distribution of this stress was investigated by Maxwell; [2] he found that in a medium whose specific inductive capacity was K, and at a point where the electromotive force is R, a tension equal to $KR^2/8\pi$ per unit area along the lines of force combined with a pressure of the same amount at right angles to these, would produce the effects observed in the electrostatic field, that is, at a point in a dielectric, the resultant of these stresses would be a force whose components, parallel to the axes of x, y, z, are eX, eY, eZ respectively, e being the charge of electricity at the point, and X, Y, Z the components of the electromotive force. It may be observed that this system of stress could not be produced by the strain in an elastic solid at rest: this points to the kinetic origin of electrostatic phenomena.

These stresses are in equilibrium at a point in a dielectric where there is no free electricity. At the junction of two media, whose specific inductive capacities are K_1 and K_2, and in which the electromotive forces are R_1 and R_2, and whose interface is perpendicular to the lines of forces, the stresses are not in equilibrium, but there is an unbalanced stress $(K_1 R_1^2 - K_2 R_2^2)/8\pi$ which will tend to make the boundary move towards the medium whose specific inductive capacity is K_1; if these dielectrics are liquids, their interface may become curved so that the forces due to surface tension balance this stress.

Quincke,[3] who has experimentally investigated the effects of electrification on various dielectrics, such, for example, as the effects on the glass of a Leyden jar, has found that the effects on different bodies are very different; he finds, for example, that though the effect of the electrification on the dielectric of the Leyden jar is generally to produce an expansion, yet in some substances, such as the fatty oils, contraction takes place.[4] This diversity in the effects of electrification on different dielectrics shows that the distribution of stress cannot be so simple as was supposed by Maxwell. It also shows that there must be forces in the electric field which are not recognised either by Maxwell's theory or the theory of action at a distance. More general theories have been given in order to meet this difficulty.

[1] *Experimental Researches*, § 1297.

[2] *Electricity and Magnetism*, 2nd edition, p. 149.

[3] *Wied. Ann.*, x. pp. 161, 374, 513; *Ibid.*, ix. p. 105; *Phil. Mag.*, vol. x. p. 30 (1880).

[4] The fatty oils are also an exception to the rule that the index of refraction equals the square root of the specific inductive capacity.

v. Helmholtz [1] has supposed that a change in the density of a dielectric might alter its specific inductive capacity, and he has investigated the consequences of this supposition. Korteweg and Lorberg [2] have investigated the more general case, when the specific inductive capacity of a strained dielectric is supposed to be a function of the strains. Korteweg supposes that if the body suffers dilatation e along the lines of force, and dilatations f and g at right angles to them, then the specific inductive capacity $= \mathrm{K} - \alpha e - \beta\ (f+g)$. Helmholtz assumed that $\alpha = \beta$. The presence of strain in a dielectric must influence the specific inductive capacity, for Quincke has shown that the various coefficients of elasticity are altered under the influence of electricity. Lorberg, l.c., has found the distribution of stress in the medium when the specific inductive capacity alters in this way. He finds that there is a tension along the line of force equal to

$$\left(\frac{\mathrm{K}}{8\pi} + \frac{\alpha}{2}\right) \mathrm{R}^2$$

and a pressure at right angles to them equal to

$$\left(\frac{\mathrm{K}}{8\pi} - \frac{\beta}{2}\right) \mathrm{R}^2$$

The force in the medium parallel to the axis of x

$$= - \rho \frac{d\phi}{dx} + \mathrm{A}$$

where

$$\mathrm{A} = - \frac{\mathrm{R}^2}{4\pi} \frac{d\mathrm{K}}{dx} + \frac{d}{dx} (\beta\, \mathrm{R}^2) + \frac{d}{dx} (\alpha - \beta) \frac{d\phi^2}{dx} + \frac{d}{dy} (\alpha - \beta) \frac{d\phi}{dx} \frac{d\phi}{dy}$$
$$+ \frac{d}{dz} (\alpha - \beta) \frac{d\phi}{dx} \frac{d\phi}{dz}$$

Where ϕ is the potential, and ρ the volume density of the free electricity. The part A of this force exists even when there is no free electricity at the place under consideration; if the dielectric were a fluid, these terms would indicate forces tending to move the fluid when placed in a variable electric field; this motion, however, seems not to have been observed. The supposition made by Korteweg and Lorberg is not the most general one that could be made; we might assume that the specific inductive capacity of the strained body became different in different directions, so that the body would behave like a crystal. Dr. Kerr's experiments on the double refraction in liquids placed between the poles of a powerful electrical machine seem to point to this conclusion.

Kirchhoff [3] has made similar assumptions to those of Korteweg and Lorberg on the effect of strain on the specific inductive capacity, and has arrived at similar equations; in the second paper he applies these equations to some cases which Quincke investigated experimentally.

Second Report of the Committee, consisting of Professor SCHUSTER (*Secretary*), Professor BALFOUR STEWART, Professor STOKES, Mr. G. JOHNSTONE STONEY, Professor Sir H. E. ROSCOE, Captain ABNEY, *and* Mr. G. J. SYMONS, *appointed for the purpose of considering the best methods of recording the direct intensity of Solar Radiation.*

THE Committee, working on the lines of their last report, have given their attention to the best form of a self-recording actinometer, and have come to the following conclusions :—

1. It seems desirable to construct an instrument which would be a modification of Professor Stewart's actinometer adapted for self-registration—the quantity to be observed being, not the rise of temperature of the inclosed thermometer after exposure for a given time, but the excess of its temperature when continuously exposed over the temperature of the envelope.

2. As the grant to the Committee will not admit of the purchase of a heliostat, it will no doubt be possible to procure the loan of such an instrument, and, by making by its means sufficiently numerous comparisons of the instrument proposed by the Committee with an ordinary actinometer, to find whether the arrangement suggested by the Committee is likely to succeed in practice. The Committee would therefore confine their action for the present to the carrying out of such a series of comparisons.

3. The size of the instrument might be the same as that of Professor Stewart's actinometer.

4. The instrument should have a thick metallic enclosure, as in the actinometer above mentioned, and in this enclosure there should be inserted a thermometer to record its temperature. Great pains should therefore be taken to construct this enclosure so that its temperature shall be the same throughout.

5. The interior thermometer should be so constructed as to be readily susceptible of solar influences. It is proposed to make it of dark glass, of such kind as to be a good absorber, and to give it a flattened surface in the direction perpendicular to the light from the hole.

6. It seems desirable to concentrate the sun's light by means of a lens upon the interior thermometer, as in the ordinary instrument. For if there were no lens the hole would require to be large, and it would be more difficult to prevent the heat from the sky around the sun from interfering with the determination. Again, with a lens there would be great facility in adjusting the amount of heat to be received by employing a set of diaphragms. There are thus considerable advantages in a lens, and there does not appear to be any objection to its use.

The Committee have not drawn their grant (20*l.*). They suggest that they be reappointed, and that the unexpended sum of 20*l.* be again placed at their disposal.

Report on Optical Theories.

By R. T. GLAZEBROOK, *M.A., F.R.S.*

DR. LLOYD'S well-known Report on Physical Optics was presented to the Association at its meeting in Dublin in 1834—fifty-one years ago. Since that time the question of double refraction has been treated of very fully by Professor Stokes in the Report for 1862, but unfortunately he confined himself to that one branch of the subject. The years immediately succeeding that in which Dr. Lloyd's report was read were marked by work of great importance, which has formed the basis for much that has since been done, and it is necessary, before writing of recent progress in the subject, to consider somewhat carefully the researches of Green, MacCullagh, Cauchy, and F. Neumann.

This I propose to do, in as brief a manner as possible, for that part of the subject which is not included in Professor Stokes's report. I then propose to go on to the consideration of more modern work, treating separately (1) of the simple elastic solid theory, (2) of theories based on the mutual reactions of matter and ether, (3) of the electro-magnetic theory.

PART I.—INTRODUCTION.

THE WORK OF MACCULLAGH, NEUMANN, GREEN, AND CAUCHY.

Chapter I.—MACCULLAGH.

§ 1. Fresnel[1] himself had developed a theory of reflexion and refraction, and had arrived at formulæ giving the intensities of the reflected and refracted waves in terms of the incident.

In obtaining these he relied on the two following principles :—

The resolved parts of the displacements parallel to the face of incidence are the same in the two media.

The total energy in the reflected and refracted waves is equal to that in the incident wave.

He further supposed that the rigidity of the ether is the same in all transparent media, and hence that reflexion and refraction are produced by a change of density ; from this it follows that the refractive index of a medium is proportional to the square of the density of the ether in the medium. The direction of vibration is considered to be perpendicular to the plane of polarisation. According to this theory there is a discontinuity in the component of the vibration at right angles[2] to the surface.

§ 2. An elegant geometrical expression of the laws to which these principles lead was given by MacCullagh. He defines as the transversal of a ray the line of intersection of the wave front and the plane of polarisation ; the length of this line being proportional to the

[1] Fresnel, *Ann. de Chim. et de Physique*, t. xlvi. p. 225 ; *Œuvres complètes*, t. i. p. 767.

[2] For a further consideration of this point see p. 186.

amplitude of the vibration multiplied by the density of the medium. Then Fresnel's results may be expressed by the statement that the transversal of the incident ray is the resultant, in the mechanical sense of the word, of those of the reflected and refracted rays.

This first suggestion of MacCullagh's was modified by reading some of Cauchy's work on double refraction, from which it appeared possible that the vibrations of polarised light might lie in the plane of polarisation instead of at right angles to it. Adopting, then, this hypothesis, a transversal represents in addition the direction of vibration; and if the further supposition is made that the ether is of the same density in all media, so that reflexion and refraction arise from variations in its rigidity and not in its density, expressions very nearly identical with Fresnel's can be found for the intensities of the reflected and refracted rays, while at the same time the principle of the continuity of the displacement normal to the surface is satisfied.

§ 3. These three principles—

(1) The ether is of the same density in all media,

(2) The displacement is the same on both sides of the surface of separation of the two media,

(3) The energy of the incident wave is equal to that of the reflected and refracted waves

—were applied by MacCullagh to the problem of reflexion and refraction at the surface of a crystal, and the results of a first investigation were communicated to the meeting of the Association in 1834.

The theory as there given was somewhat modified in consequence of a paper by Seebeck in Poggendorff's 'Annalen,' and took its final form in a memoir read before the Irish Academy [1] in January 1837. MacCullagh in this paper states his fundamental principles, not as based on mechanics, but merely as those which had led him to a solution, the results of which agree closely with the experiments of Seebeck and Brewster.

The analysis of the problem is greatly simplified by the introduction of the idea of 'uniradial directions.'

In a crystal, for any given direction of incidence, there are two positions for the incident transversals, which give rise each to only one refracted ray—there are corresponding positions for the reflected transversals. These directions of the incident transversals are the *uniradial* directions.

For a uniradial direction the incident, reflected, and refracted transversals lie in one plane, and the refracted transversal is the resultant of the other two.

The transversal is normal to the plane containing the ray and the wave normal. The polar plane is defined as a plane through the transversal and parallel to the line joining the extremity of the ray to the point in which the wave normal meets the surface of wave slowness, here designated the 'index surface.'

It is hence proved that for a uniradial direction the incident and reflected transversals lie in the polar plane of the refracted ray, and then the principles of equivalence of vibrations and of *vis viva* lead to equations to determine the relation between the azimuths of the transversals referred to the plane of incidence.

[1] MacCullagh, 'On the Laws of Crystalline Reflexion and Refraction,' January, 1837, *Trans. of Royal Irish Academy*, vol. xviii.

These give—

$$\left.\begin{aligned} \tan\theta &= \cos(\phi-\phi')\tan\theta' + \frac{\sin^2\phi'\tan\chi}{\cos\theta'\sin(\phi+\phi')} \\ \tan\theta_1 &= -\cos(\phi+\phi')\tan\theta' + \frac{\sin^2\phi'\tan\chi}{\cos\theta'\sin(\phi-\phi')} \end{aligned}\right\} \quad . \quad (1)$$

with exactly similar formulæ for the other uniradial direction; θ, θ_1, and θ' are the azimuths of the transversals in the incident, reflected, and refracted waves measured from the plane of incidence, and χ the angle between the ray and the wave normal. In the general case the incident vibration is resolved into two in the uniradial directions, and each considered separately. When the two values of θ_1, found from these, are equal, the partial reflected transversals coincide; the value of θ_1 at which this takes place is the deviation, and the angle of incidence the polarising angle.

The theory is applied to Iceland spar, and agrees with experiments of Brewster and Seebeck.

§ 4. The same problem is considered by Neumann [1] in a long paper read in 1835 before the Berlin Academy, and in a second memoir published separately in Berlin [2] in 1837, and the same results deduced from similar hypotheses.

§ 5. In 1839 MacCullagh [3] attempted to found his theory on a dynamical basis by finding an expression for the potential energy of the ether when strained by the passage of the waves of light, and applying to the expressions thus obtained Laplace's principle of virtual velocities.

This leads to a volume integral which holds throughout the space occupied by the medium, and a surface integral to be taken over the boundary.

The surface integral taken in connection with the principle of the continuity of the displacement gives the conditions at the surface, and these are shown to be identical with the conditions found in the previous paper.

Professor Stokes, in the Report on Double Refraction, has pointed out the error in the fundamental expression assumed by MacCullagh for the energy, and this error of course affects the theory of reflexion.

Chapter II.—Green.

§ 1. The correct expression for the energy, and the correct laws of reflexion and refraction on a strict elastic solid theory, had at the date of MacCullagh's paper been given by George Green [4] in a memoir read before the Cambridge Philosophical Society in December 1837.

The potential energy of the medium is shown to be a function (ϕ) of the three principal elongations s_1, s_2, s_3, and the three principal shearing-strains α, β, γ.

[1] Neumann, 'Theoretische Untersuchung der Gesetze nach welchen das Licht an der Gränze zweier vollkommenen durchsichtigen Medien reflectirt und gebrochen wird.'

[3] MacCullagh, 'An Essay towards a Dynamical Theory of Crystalline Reflexion and Refraction,' *Trans. of Royal Irish Academy*, vol. xxi.

[4] Geo. Green, 'On the Laws of Reflexion and Refraction of Light at the Common Surface of two Non-crystallised Media,' *Camb. Phil. Trans.* 1838, and *Papers of the late Geo. Green*, p. 243.

This function is then expanded in the form

$$\phi = \phi_0 + \phi_1 + \phi_2 + \cdot \;.\;.\;.$$

ϕ_0, &c., being homogeneous functions of the orders 0, 1, 2 of the small quantities s_1, s_2, &c.

The equations of motion depend on $\delta\phi$, and so, ϕ_0 being constant, it does not appear. If the medium in its equilibrium position is unstrained ϕ_1 vanishes also, and in general ϕ_2 contains twenty-one arbitrary coefficients. ϕ_3 may be neglected compared with ϕ_2. If the medium be not initially free from strain, ϕ_1 will introduce six more coefficients, so that finally we find the most general form of ϕ for our purposes involves twenty-seven coefficients.[1]

Green then supposes the medium to be symmetrical with regard to three rectangular planes, and obtains finally as the form for ϕ, taking the case in which the medium is initially strained, the value—

$$\begin{aligned} -2\phi = {} & 2\mathrm{A}\frac{du}{dx} + 2\mathrm{B}\frac{dv}{dy} + 2\mathrm{C}\frac{dw}{dz} \\ & + \mathrm{A}\left\{\left(\frac{du}{dx}\right)^2 + \left(\frac{dv}{dx}\right)^2 + \left(\frac{dw}{dx}\right)^2\right\} \\ & + \mathrm{B}\left\{\left(\frac{du}{dy}\right)^2 + \left(\frac{dv}{dy}\right)^2 + \left(\frac{dw}{dy}\right)^2\right\} \\ & + \mathrm{C}\left\{\left(\frac{du}{dz}\right)^2 + \left(\frac{dv}{dz}\right)^2 + \left(\frac{dw}{dz}\right)^2\right\} \\ & + \mathrm{G}\left(\frac{du}{dx}\right)^2 + \mathrm{H}\left(\frac{dv}{dy}\right)^2 + \mathrm{I}\left(\frac{dw}{dz}\right)^2 \\ & + 2\mathrm{P}\frac{dv}{dy}\frac{dw}{dz} + 2\mathrm{Q}\frac{du}{dx}\frac{dw}{dz} + 2\mathrm{R}\frac{du}{dx}\frac{dv}{dy} \\ & + \mathrm{L}\left(\frac{dv}{dz} + \frac{dw}{dy}\right)^2 + \mathrm{M}\left(\frac{du}{dz} + \frac{dw}{dx}\right)^2 + \mathrm{N}\left(\frac{du}{dy} + \frac{dv}{dx}\right)^2 \qquad (1) \end{aligned}$$

If the medium be initially unstrained A=B=C=0, while, further, if it be completely isotropic,

$$\left.\begin{aligned} &\mathrm{G} = \mathrm{H} = \mathrm{I} = 2\mathrm{N} + \mathrm{R} \\ &\mathrm{L} = \mathrm{M} = \mathrm{N} \\ &\mathrm{P} = \mathrm{Q} = \mathrm{R}. \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (2)$$

And introducing two new constants, A and B,

$$\begin{aligned} -2\phi_2 = {} & \mathrm{A}\left(\frac{du}{dx} + \frac{dv}{dy} + \frac{dw}{dz}\right)^2 \\ & + \mathrm{B}\left\{\left(\frac{du}{dy} + \frac{dv}{dx}\right)^2 + \left(\frac{du}{dz} + \frac{dw}{dx}\right)^2 + \left(\frac{dv}{dz} + \frac{dw}{dy}\right)^2\right. \\ & \left. - 4\left(\frac{dv}{dy}\frac{dw}{dz} + \frac{dw}{dz}\frac{du}{dx} + \frac{du}{dx}\frac{dv}{dy}\right)\right\} \quad . \quad . \quad . \quad . \quad (3) \end{aligned}$$

[1] For the difference between this and Cauchy's theory see Prof. Stokes's report.

According to Green's theory of double refraction, founded simply on the supposition that the displacements are in the wave front in a crystal,

$$\left.\begin{aligned} \mathrm{G}=\mathrm{H}=\mathrm{I}&=\mu, \text{ say} \\ \mathrm{P}&=\mu-2\mathrm{L} \\ \mathrm{Q}&=\mu-2\mathrm{M} \\ \mathrm{R}&=\mu-2\mathrm{N} \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (4)$$

The equations of motion are given by

$$\iiint dx\,dy\,dz\left\{\rho\left(\frac{d^2u}{dt^2}\,\delta u+\frac{d^2v}{dt^2}\,\delta v+\frac{d^2w}{dt^2}\,\delta w\right)-\delta\phi\right\}=0 \quad . \quad . \quad (5)$$

In treating of the problem of reflexion this integral is applied to the whole of the two media, and is transformed by partial integration into a volume integral, which may be written

$$\iiint dx\,dy\,dz\left\{\left(\rho\frac{d^2u}{dt^2}-\mathrm{X}\right)\delta u+\left(\rho\frac{d^2v}{dt^2}-\mathrm{Y}\right)dv+\left(\rho\frac{d^2w}{dt^2}-\mathrm{Z}\right)\delta w,\right.$$

and a surface integral, which we may write

$$\begin{aligned} \iint & dy\,dz\,(\overline{\mathrm{X}}\,\delta u-\overline{\mathrm{X}}_1\,\delta u_1) \\ & +dz\,dx\,(\overline{\mathrm{Y}}\,\delta v-\overline{\mathrm{Y}}_1\,\delta v_1) \\ & +dx\,dy\,(\overline{\mathrm{Z}}\,\delta w-\overline{\mathrm{Z}}_1\,\delta w_1). \end{aligned}$$

These two integrals must vanish separately. Green's work as to the former, on which the propagation of light depends, has been considered by Professor Stokes. It leads to the three equations—

$$\left.\begin{aligned} \rho\frac{d^2u}{dt^2}&=(\mathrm{A}-\mathrm{B})\frac{d}{dx}\left(\frac{du}{dx}+\frac{dv}{dy}+\frac{dw}{dz}\right)+\mathrm{B}\nabla^2u \\ \rho\frac{d^2v}{dt^2}&=(\mathrm{A}-\mathrm{B})\frac{d}{dy}\left(\frac{du}{dx}+\frac{dv}{dy}+\frac{dw}{dz}\right)+\mathrm{B}\nabla^2v \\ \rho\frac{d^2w}{dt^2}&=(\mathrm{A}-\mathrm{B})\frac{d}{dz}\left(\frac{du}{dx}+\frac{dv}{dy}+\frac{dw}{dz}\right)+\mathrm{B}\nabla^2w \end{aligned}\right\} \quad . \quad . \quad (6)$$

which form the basis of the whole theory of isotropic elastic solids.

§ 2. The latter integral equated to zero gives us the surface conditions; for over the surface, according to Green, who treats the ether in the two media as two separate elastic solids always in contact with each other, we must have

$$u=u_1,\ v=v_1,\ w=w_1, \quad . \quad . \quad . \quad . \quad (7)$$

and hence

$$\overline{\mathrm{X}}=\overline{\mathrm{X}}_1,\ \overline{\mathrm{Y}}=\overline{\mathrm{Y}}_1,\ \overline{\mathrm{Z}}=\overline{\mathrm{Z}}_1, \quad . \quad . \quad . \quad . \quad (8)$$

These six equations determine the motion completely.

Using Green's notation, and considering only the case of two homogeneous media, let us take the plane $x=0$ as the separating surface. Then the surface conditions become

$$u=u_1,\ v=v_1,\ w=w_1,$$

$$\left.\begin{aligned}
&A\left(\frac{du}{dx}+\frac{dv}{dy}+\frac{dw}{dz}\right)-2B\left(\frac{dv}{dy}+\frac{dw}{dz}\right)\\
&=A_1\left(\frac{du_1}{dx}+\frac{dv_1}{dy}+\frac{dw_1}{dz}\right)-2B_1\left(\frac{dv_1}{dy}+\frac{dw_1}{dz}\right)\\
&B\left(\frac{du}{dy}+\frac{dv}{dx}\right)=B_1\left(\frac{du_1}{dy}+\frac{dv_1}{dx}\right)\\
&B\left(\frac{du}{dz}+\frac{dw}{dx}\right)=B_1\left(\frac{du_1}{dz}+\frac{dw_1}{dx}\right)
\end{aligned}\right\} \quad . \quad . \quad . \quad (9)$$

when $x=0$.

The problem now resolves itself into two cases. Let us take the plane of incidence as the plane xy, and suppose that the vibrations in the incident wave are perpendicular to this, then—

CASE I.—Light polarised in the plane of incidence,

$$u=u_1=v=v_1=0,$$

and the conditions are

$$\left.\begin{aligned} w&=w_1\\ B\frac{dw}{dx}&=B_1\frac{dw_1}{dx}\end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad (10)$$

Now, we have seen that Fresnel originally assumed that the rigidity of the ether is the same in all media, and the density different. Green, adopting this view, puts $B=B_1$, $A=A_1$,* and the above formulæ lead him to results agreeing with those given by Fresnel's simple theory for this case, while, by making the angle of refraction imaginary, it is shown that the wave, when totally reflected, undergoes just the change of phase given by Fresnel.

CASE II.—Light polarised at right angles to the plane of incidence, the vibrations being therefore in that plane.

Then $w=w_1=0$, and the surface conditions are

$$u=u_1,\ v=v_1,$$

$$\left.\begin{aligned}
A\left(\frac{du}{dx}+\frac{dv}{dy}\right)-2B\frac{dv}{dy}&=A_1\left(\frac{du_1}{dx}+\frac{dv_1}{dy}\right)-2B_1\frac{dv_1}{dy}\\
B\left(\frac{du}{dy}+\frac{dv}{dx}\right)&=B_1\left(\frac{du_1}{dy}+\frac{dv_1}{dx}\right)
\end{aligned}\right\} \quad . \quad (11)$$

We have here four equations to determine two unknowns, viz. the intensities of the reflected and refracted rays, and it is clear, therefore, that two more quantities must come under consideration.

Now, in the general case it follows from the equations of motion given above that two waves can traverse the medium. In the one of these the vibrations are transverse, and travel with the velocity $\sqrt{B/\rho}$. This constitutes the light-wave. In the other the vibrations are longitudinal, and travel with the velocity $\sqrt{A/\rho}$. In the case before us, then, reflexion gives rise to both these, and we have two reflected and two refracted waves. But experi-

* The physical meaning of these constants and the relations implied by these conditions will be considered later, see p. 167.

ment tells us, to a high degree of approximation, that the whole of the energy of the incident light appears in the reflected and refracted light. We are therefore forced to suppose not merely that the longitudinal wave does not affect our eyes as light, but also that it does not absorb any material part of the incident energy. This conclusion is confirmed when we recollect that on arriving at a second refracting surface this longitudinal wave would, if it existed, set up transverse vibrations which would be visible, so that on passing through a prism, for example, there would always be two emergent rays.

Now, Green shows that very little energy will be absorbed by the longitudinal vibrations, provided that the ratio A/B be very small or very great; and, further, that the condition of stability of the medium requires that A/B should be greater than 4/3. He therefore concludes that A/B is very great—practically infinite, or that the wave of longitudinal vibrations travels with a velocity enormously greater than that of light.

The equations are then solved, assuming that $B=B_1$ and $A=A_1$,* by the substitutions—

$$\left.\begin{aligned} u &= \frac{d\phi}{dx} + \frac{d\psi}{dy} \\ v &= \frac{d\phi}{dy} - \frac{d\psi}{dx} \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (12)$$

The symbol ϕ represents the longitudinal or, as Sir Wm. Thomson has called it, the pressural wave, and ψ the transverse or light wave.

It is shown that by the reflexion a difference of phase is produced between the reflected and incident and the refracted and incident waves, and expressions are found for the intensities of the reflected and refracted waves in terms of that of the incident. According to these expressions, the intensity of the reflected wave never vanishes, but reaches a minimum when $\varphi + \phi' = 90°$. The minimum value of the ratio of the two intensities will be for air and water about 1/151, while for a diamond or other substance of great refractive index it would be much greater still.

§ 3. This result, then, of the theory is in direct antagonism to the fact that light is very nearly completely polarised by reflexion from most transparent surfaces at the polarising angle, while the values found for the change of phase do not agree with the experiments of Jamin,[1] Quincke, and others, and the theory as left by Green is certainly incorrect. We shall, however, return to this point later.[2]

Green does not apply his equations to the problem of crystalline reflexion, and, indeed, his theories of reflexion and of double refraction are entirely inconsistent, for the former supposes the ether to have the same rigidity in all bodies, while the latter attempts to explain double refraction by making the rigidity of a crystal a function of the direction of the strain.

* This last equation, as we shall see later, is not necessary.

Chapter III.—Cauchy.

§ 1. Cauchy's optical researches were being published about this same period, and a very full and interesting account of them, and of the work of other French authors, is given by M. de St. Venant in a paper to which I am greatly indebted for much valuable information.[1]

Cauchy's work on elastic solids began in 1822, and in 1829 he presented to the Academy his first memoir on isotropic media. His more generally known memoir followed in 1830,[2] containing his work on double refraction and the propagation of light in a crystal. An account of this is given in Professor Stokes's report in 1862. His first work on dispersion, which he explained (following a suggestion of Coriolis) by the addition of terms involving differential coefficients above the second, was published in 1830.[3] The great memoir, 'Sur la dispersion de la lumière,' in which he developed this principle, appeared between 1830 and 1836;[4] and in this same memoir he first considered the problem of reflexion and refraction, which led him to the idea of elliptic polarisation and a more general expression for the possible displacements of a molecule[5] in a plane wave.

§ 2. Further considerations on the subject of reflexion and refraction led him to conclude that, in order to obtain Fresnel's expressions for the intensities of the reflected and refracted rays in terms of that of the incident, it was necessary that not only the displacements, but their differential coefficients with respect to the normal to the surface of separation, should be continuous across that surface. This continuity had to be rendered compatible with the rest of his theory, in which the ether is considered as differing both in density and elasticity in different media.[6] It is, however, quite inconsistent with the true surface conditions established by Green, Neumann, and MacCullagh on their various hypotheses—the conditions, namely, that the displacements and the stresses over the surface should be the same in the two media; and Cauchy, in consequence, was led to conclude that the method of Lagrange, by which the above conditions were first established, is inapplicable to questions of this kind.[7] But, as St. Venant points out, these surface conditions do not in the least depend on Lagrange's method of virtual velocities, but on the fundamental elementary principles of mechanics, and can never be reconciled with Cauchy's theory of continuity so long as it is supposed that the rigidity of the ether varies from one body to another.

§ 3. In 1839[8] Cauchy re-established his equations of motion for an isotropic medium, basing them on analytical considerations of symmetry. For a perfectly isotropic body he arrived at the equations—

$$\rho \frac{d^2u}{dt^2} = (\mathrm{A}-\mathrm{B})\frac{d\theta}{dx} + \mathrm{B}\nabla^2 u \qquad . \quad . \quad . \quad (13)$$

&c., where
$$\theta = \frac{du}{dx} + \frac{dv}{dy} + \frac{dw}{dz},$$

already given by Green.[1] And in cases in which the axes can only be turned together about the origin, a third coefficient comes in, in the form of terms, such as

$$C\left(\frac{dw}{dy}-\frac{dv}{dz}\right).$$

In 1849[2] Cauchy propounded the idea that the ether atoms in a body such as a crystal are disposed, as it were, in shells round the matter atoms in such a manner as to have different elastic properties at different points of the same shell; the shells, however, are regularly placed, and the properties of the ether repeat themselves at similar points in the different shells. It results from this that the constants in the equations of motion will be periodic functions of the equilibrium positions of the molecules, and for optical effects we have to do with the average displacement over a small volume of the medium.[3]

The general equations established by Cauchy lead to a normal wave travelling with a velocity equal to $\sqrt{A/\rho}$. According to his earlier theory, resting on the law of action between the molecules of ether, A and B are not independent, and it is possible by suitably choosing the law of force to make A vanish or even be negative. The theory[4] of reflexion and refraction led him to conclude that A was a small negative quantity, so that the normal disturbance ceases to be propagated as such.

§ 4. Cauchy's work was continued by Briot,[5] starting from the equations of motion deduced from the mutual action between two particles of ether, and the supposition suggested by Cauchy that the ether within a crystal is in a state of unequal strain. In treating of dispersion Briot points out that it cannot be explained in the manner originally suggested by Cauchy, for there is no reason why the terms in his differential equations from which it arises should be insensible in a vacuum if they are sensible in ordinary transparent media. He therefore makes it depend on terms arising from a periodic distribution of the ether within material bodies, and shows that to obtain Cauchy's dispersion formula the law of action between the molecules must be as the inverse sixth power of the distance. In his memoir on reflexion and refraction, however, he adopts Cauchy's views as to the disappearance of the normal wave, and this is quite inconsistent with the above law, while the ether and matter molecules must attract each other with a force varying as the inverse square of the distance.

§ 5. The problem of reflexion and refraction for both isotropic and crystalline bodies is treated of in a memoir published in 1866–67,[6] starting from Cauchy's principle of continuity, to which he gives an extended meaning in the second memoir. He at first supposes the vibrations in the crystal to be rigorously in the plane of the wave, and, adopting MacCullagh's methods of the uniradial direction, arrives at his equations. The work is then extended to the general case in which the vibrations

are quasi-transversal, and it is shown how the simpler forms of the equations are modified by this.

Thus, for the uniradial directions in the case in which the longitudinal disturbance is supposed to be strictly normal to the wave, if χ is the angle between the ray and the wave normal, θ, θ', and θ_1 the azimuths of the planes of polarisation, measured from the plane of incidence, of the incident reflected and refracted waves, ϕ and ϕ' the angles of incidence and refraction, and m a quantity depending on the angle between the plane of the wave and the direction of vibration, then—

$$\left.\begin{aligned}\tan\,\theta &= \tan\,\theta'\cos\,(\phi - \phi') + \frac{m\,\sin^2\,\phi'\,\tan\,\chi}{\cos\,\theta'\,\sin\,(\phi + \phi')}\\ \tan\,\theta_1 &= \tan\,\theta'\cos\,(\phi + \phi') - \frac{m\,\sin^2\,\phi'\,\tan\,\chi}{\cos\,\theta'\,\sin\,(\phi - \phi')}\end{aligned}\right\} \quad . \quad (14)$$

These formulæ agree with those of MacCullagh if we put $m = 1$.

Chapter IV.—Elliptic Polarisation. Comparison of Results.

§ 1. The peculiar phenomena presented by quartz had been explained by Airy in 1831 [1] on the assumption that the two waves were elliptically polarised. In 1836 [2] MacCullagh made a further advance, and showed how the addition of certain terms to the differential equations of motion would lead to the elliptic polarisation required by Airy's theory. The equations assumed by MacCullagh, for the existence of which he does not attempt to assign a mechanical reason, were—

$$\left.\begin{aligned}\frac{d^2u}{dt^2} &= A\frac{d^2u}{dz^2} + C\frac{d^3v}{dz^3}\\ \frac{d^2v}{dt^2} &= B\frac{d^2v}{dz^2} - C\frac{d^3u}{dz^3}\end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (15)$$

Where $A = a^2$, $B = a^2 - (a^2 - b^2)\sin^2\theta$,

a and b being constants, and θ the angle between the optic axis and the wave normal—the axis of z. The two waves resulting from these equations are shown to be elliptically polarised, while their velocity is given by the equation

$$(w^2 - A)\,(w^2 - B) = \frac{4\pi^2C^2}{\lambda^2} \quad . \quad . \quad . \quad . \quad (16)$$

λ being the wave length. The rotation of the plane of polarisation produced by the passage of a plane polarised ray through a plate of crystal cut at right angles to the axis, and of unit thickness, is $2\pi^2C/a^4\lambda^2$.

MacCullagh shows that the results of this hypothesis as to the form of the equations agree fairly with Airy's experiments, and that the agreement would be made somewhat more close by the hypothesis that C varies slightly with θ.

[1] Airy, 'On the Nature of the Two Rays produced by the Double Refraction of Quartz,' *Camb. Phil. Soc. Trans.* vol. iv. pp. 79, 198.

[2] MacCullagh, 'On the Laws of the Double Refraction of Quartz,' *Irish Trans.* vol. xvii. p. 461.

§ 2. Terms of a similar kind were first applied by Airy [1] to explain the magnetic rotation of the plane of polarisation discovered by Faraday. Airy starts by calling attention to the fundamental difference between the rotation produced by quartz and that due to magnetic action. In quartz, sugar, etc., by reflecting the ray back along its original path the rotation is reversed, so that the ray emerges with its plane of polarisation unaltered, while in bodies under magnetic action the rotation is doubled by the same process. It is as if the former effect were due to a heliacal arrangement of the molecules, the latter to a continuous rotation of them round the lines of force. Airy shows that the effects produced can be accounted for by the introduction into the equation for u of terms involving odd differential coefficients of v with respect to the time, and he works out the case in which the equations are

$$\left.\begin{aligned}\frac{d^2u}{dt^2} &= A\frac{d^2u}{dz^2} + C\frac{dv}{dt}\\ \frac{d^2v}{dt^2} &= A\frac{d^2v}{dz^2} - C\frac{du}{dt}\end{aligned}\right\} \quad . \quad . \quad . \quad (17)$$

The two possible velocities for a wave of period τ are given by

$$v_1{}^2 = \frac{A}{1+\frac{\tau}{2\pi}C}, \qquad v_2{}^2 = \frac{A}{1-\frac{\tau}{2\pi}C}.$$

It is pointed out also that terms such as $\dfrac{d^3v}{dz^2dt}$ or $\dfrac{d^3v}{dt^3}$ would also lead to the effect observed; though they would differ in the law, expressing the relation between the velocity and the wave length. Airy remarks that 'the equations are given, not as offering a mechanical explanation of the phenomena, but as showing that they may be explained by equations, which equations appear such as might be introduced by some plausible mechanical assumption.'

§ 3. The attempt to estimate the relative value of the theories of reflexion and refraction just developed is rendered easier if we consider the physical meaning of the two constants involved. The importance of this has been continually insisted upon by Sir Wm. Thomson [2] in his numerous writings on the subject of elasticity, which have done so much to clear away difficulties and obscurities; and though these writings belong to the later period of our subject, we shall consider here some of the results they lead to.

To Green, Cauchy, and MacCullagh, A and B are constants, appearing in the most general form of the equations, and on which the rate of propagation of waves depends; their connection with the other physical properties of the solids is not considered. Now an isotropic elastic solid is one which possesses the power of opposing resistance (1) to change of shape, (2) to change of volume, and has in consequence only two principal moduluses of elasticity.

[1] Airy, 'On the Equations applying to Light under the Action of Magnetism,' *Phil. Mag.* (3), vol. xxviii. p. 469.

[2] See especially, Thomson, 'Elements of a Mathematical Theory of Elasticity,' *Phil. Trans.* 1856, p. 481; Thomson and Tait, *A Treatise on Natural Philosophy*, vol. i.; Thomson, article 'Elasticity,' *Encyclopædia Britannica*, ninth edition, 1880.

On the value of the one, the rigidity, n, in the notation of Thomson and Tait, depends the resistance which the body can oppose to a stress tending to produce distortion or change of shape without change of volume, and it is measured by the ratio of the shearing stress—or stress tending to produce distortion—to the strain or alteration of shape produced. It can be shown that this is equal to the constant, B, of Green's theory. And the velocity of a wave of transverse displacement, since it does not produce changes in the volume of the body through which it passes, depends only on the ratio of the rigidity to the density.

On the value of the other principal modulus depends the resistance which the body can offer to compression or change of volume when subjected to a uniform hydrostatic pressure at all points of its surface. The compression produced is measured by the ratio of the change in volume to the original volume, and the modulus of compression, k, is the ratio of the stress to the compression it produces.

It has been shown by Thomson that the relation between A and the principal moduluses is given by the equation $A = k + \frac{4}{3}n$, so that k, the modulus of compression, is equal to $A - \frac{4}{3}B$.

The expression for the stresses arising from simple elongations e, f, g in the directions of the axes, and from simple shears α, β, γ round the axes, are found; they are

$$\begin{aligned} N_1 &= (k + \tfrac{4}{3}n)e + (k - \tfrac{2}{3}n)(f + g) \\ &= (k + \tfrac{4}{3}n)(e + f + g) - 2n(f + g) \\ &= A\left(\frac{du}{dx} + \frac{dv}{dy} + \frac{dw}{dz}\right) - 2B\left(\frac{dv}{dy} + \frac{dw}{dz}\right), \end{aligned}$$

etc., using Green's notation, and

$$T_3 = n\alpha = B\left(\frac{dv}{dz} + \frac{dw}{dy}\right),$$

etc., and from these Green's expression for the energy can be obtained. We may note that the velocity of propagation of the longitudinal waves $\sqrt{A/\rho}$ depends on both the modulus of compression and the rigidity.

According to the mathematical theories of Navier, Poisson, Cauchy, and De St. Venant, there is a definite relation between n and k for all bodies given by the equation $n = \frac{3}{5}k$ or $B = \frac{1}{3}A$. Stokes[1] was the first to point out that this could not be true universally, and this conclusion has been confirmed by the experiments of Wertheim and Kirchhoff for various metals.

Thus, on the assumption that the properties of the ether are those of an elastic solid, Cauchy's theory in its original form, independently of the consideration of his surface conditions, must be rejected. In his later theory, as we have said, he does admit the second constant A.[2] But, we have seen that the existence of the two constants A and B implies that there will be two waves in the medium, while the absence of the wave of normal vibrations in light, combined with the conditions of stability, requires that A should be great compared with B, and this again requires that k, the modulus of compression, should be great compared with n, the

[1] Stokes, 'On the Friction of Fluids in Motion and the Equilibrium and Motion of Elastic Solids,' *Trans. Camb. Phil. Soc.* 1845; *Math. Papers*, i. p. 75.

[2] See pp. 164, etc.

rigidity. Thus we are compelled to treat the ether as an elastic solid of very great—practically infinite—incompressibility. Now, the cubical dilatation produced by a given state of strain is measured by $e+f+g$, or $\frac{du}{dx}+\frac{dv}{dy}+\frac{dw}{dz}$, and the condition of incompressibility requires that this should be zero. It is not, however, admissible to omit the terms in $e+f+g$ in the equations, for they occur with the constant A as a factor, and the physical condition that these terms should vanish implies also that A should be very large. To obtain the correct equations we must put

$$(\mathrm{A}-\mathrm{B})\left(\frac{du}{dx}+\frac{dv}{dy}+\frac{dw}{dz}\right)=-p,$$

and they then become

$$\rho\frac{d^2u}{dt^2}=-\frac{dp}{dx}+\mathrm{B}\nabla^2u. \qquad (18)$$

et cetera.

§ 4. MacCullagh and Neumann omit the terms in p entirely from their equations, both within the medium and over the surface, and are led in consequence to erroneous results, though, as we shall see later, their theories (modified so as to include the terms) have been developed by Lord Rayleigh[1] and Lorenz. Green, as we have seen, is perfectly consistent throughout; but his final equations, unfortunately, are not confirmed by experiment. If we assume the rigidity of the ether to be the same in the two media, it is not difficult to show that Cauchy's surface conditions are identical with those of Green, or, to be more accurate, that Green's correct equations expressing the continuity of the stress and of the displacement over the surface reduce to Cauchy's. Green obtains his surface condition from the value of a certain integral over the surface; they may be obtained, perhaps more simply, from the equations of motion of an element $d\mathrm{S}$ of the surface; for, taking the case when the plane $x=0$ is the bounding surface, let ν be the thickness of the element, N_1, N_1' the stresses on it parallel to the axis of x, then we have

$$\rho\nu\, d\mathrm{S}\frac{d^2u}{dt^2}=(\mathrm{N}_1-\mathrm{N}_1')\,d\mathrm{S} \qquad (19)$$

Hence, when ν is indefinitely decreased, $\mathrm{N}_1=\mathrm{N}_1'$, with other similar equations. On Green's supposition that $\mathrm{A}=\mathrm{A}_1$, $\mathrm{B}=\mathrm{B}_1$, these conditions for Case I. (vibrations normal to the plane of incidence) lead to

$$\left.\begin{aligned} w&=w_1,\\ \frac{dw}{dx}&=\frac{dw_1}{dx};\end{aligned}\right\} \qquad (20)$$

and for Case II. (vibrations in the plane of incidence) to

$$\left.\begin{aligned} u&=u_1, & v&=v_1,\\ \frac{du}{dx}&=\frac{du_1}{dx}, & \frac{dv}{dx}&=\frac{dv_1}{dx},\end{aligned}\right\} \qquad (21)$$

which are Cauchy's conditions. The difference between the two theories lies in their treatment of the waves of longitudinal displacement.

[1] See p. 189.

According to both Green and Cauchy they depend on a function ϕ, where

$$\phi = \phi_0 e^{\iota(a'x + by + ct)} \quad . \quad . \quad . \quad . \quad (22)$$

And in both theories

$$a'^2 + b^2 = \frac{c^2\rho}{A} \quad . \quad . \quad . \quad . \quad . \quad (23)$$

Green puts A/ρ very large, so that $a'^2+b^2=0$, and

$$\phi = e^{\pm bx}\{K \sin(by + ct) + L \cos(by + ct)\} \quad . \quad . \quad (24)$$

while Cauchy, without any dynamical justification, writes $A/\rho = -c^2/k^2$, k being a large quantity, so that A is a small negative quantity. Hence $a'^2+b^2= -k^2$.

The assumption of a negative value for A leads to the conclusion that the modulus of compression is negative—that is, that the medium is such that pressure causes it to expand and tension to contract, and this alone is fatal to the theory.

§ 5. We come, then, to the conclusion that the phenomena of reflexion and refraction cannot be explained, any more than the phenomena of double refraction, on a purely elastic solid theory involving a sudden change of properties on crossing the interface. Green's theory is the only possible consistent one, and it, in its original form, leads to results differing from experiment.

Part II.—Modern Developments of the Elastic Solid Theory.

We now come to the consideration of rather more modern investigation on this subject. The limits of space will confine us to the theoretical work which has been done. The great experimental researches of Fizeau, Jamin, Quincke, Cornu, and others, will only be occasionally referred to. A complete account of these must be left for some future time.

Chapter I.—General Properties of the Ether on the Elastic Solid Theory.

The elastic solid theory of the propagation of light and double refraction has been discussed in various papers by Haughton, Lamé, St. Venant, Boussinesq, Von Lang, Sarrau, Lorenz, Rankine, Lord Rayleigh, Kirchhoff, and others.

§ 1. Haughton considered the problem of the general equations of an elastic solid in a paper read before the Irish Academy in 1846, in which he adopts Cauchy's views as to the constitution of the medium. These views are modified in a second paper,[1] read in 1849, in which the general equations are formed, and the correct expression found for the potential energy.

In this paper Haughton shows how to calculate the strain in any direction produced by a given elongation in the same direction. This strain is proved to be inversely proportional to the fourth power of the radius of a certain surface, called by Rankine the tasimonic surface. A form is found for the equation to the surface of wave slowness, which is said to reduce to MacCullagh's if the vibrations be strictly transversal; but, in making the reduction, the dilatation θ is equated to zero, its co-

[1] Haughton, 'On a Classification of Elastic Media and the Law of the Propagation of Plane Waves through them,' *Irish Trans.* vol. xxii. p. 97.

efficient remaining a finite quantity, and in consequence the results are erroneous.

§ 2. Lamé is the author of numerous papers, in the 'Comptes Rendus' and elsewhere, on the propagation of waves through an elastic medium, and his results are summed up in his 'Leçons sur l'Elasticité.' [1] The general form of the equations for the strains are shown to contain twelve constants, which become six if the dilatations be equated to zero, and three when planes of symmetry are taken for the co-ordinate planes. The equations of motion finally obtained may be written

$$\frac{d^2u}{dt^2}=c^2\frac{d}{dy}\left(\frac{du}{dy}-\frac{dv}{dx}\right)-b^2\frac{d}{dz}\left(\frac{dw}{dx}-\frac{du}{dz}\right) \quad . \quad . \quad (1)$$

etc., which agree with MacCullagh's and with Green's if we omit the terms involving the dilatation. The arguments to be advanced against the theory are identical, then, with those which Professor Stokes has urged against MacCullagh's.

§ 3. St. Venant has written many most important papers on the subject of elasticity. He still adheres to Cauchy's theory and the form of the equations of an elastic solid deduced from the hypothesis of direct action between the molecules of the medium, and in his last great work on the subject, the annotated French edition of Clebsch's 'Elasticity,' states his reasons for so doing in §§ 11, 16. However, in the work he employs Green's expression for the energy, with the twenty-one coefficients—'Vu la controverse actuelle où la majorité des avis est contraire au nôtre.'

§ 4. In a paper printed in 1863 [2] he criticises Green's theory of double refraction, arguing that Green's conditions for the tranversality of the vibrations lead to isotropy. This conclusion is frequently repeated in St. Venant's [3] papers, and it will therefore be well to investigate the point somewhat closely.

Let us suppose that we have a simple elongation ϵ in a direction l_1, m_1, n_1, in a medium fulfilling Green's conditions. Let $l_2, m_2, n_2, l_3, m_3, n_3$ be the direction cosines of two lines at right angles in a plane normal to l_1, m_1, n_1, and let us investigate the stresses $N_1', N_2', N_3', T_1', T_2', T_3'$ on the faces of an element normal to these directions. Then St. Venant's argument rests on the fact that N_1' is independent of the direction of the elongation, while T_2' and T_3' vanish, and that this would be the case in an isotropic medium. This last statement is of course true, but on Green's theory N_2', N_3' do depend on the direction, which they would not do in an isotropic medium, and T_1' has a finite value, while for an isotropic medium it would vanish.

The values for the stresses may be shown to be—

$$\left.\begin{aligned}
N_1' &= \mu\epsilon \\
N_2' &= \{\mu-2(Ll_3^2+Mm_3^2+Nn_3^2)\}\,\epsilon \\
N_3' &= \{\mu-2(Ll_2^2+Mm_2^2+Nn_2^2)\}\,\epsilon \\
T_1' &= 2\,\{Ll_2l_3+Mm_2m_3+Nn_2n_3\}\,\epsilon \\
T_2' &= T_3'=0
\end{aligned}\right\} \quad . \quad . \quad (2)$$

[1] Lamé, *Leçons sur l'Elasticité.* Paris: Gauthier Villars, 1866.

[2] St. Venant, 'Sur la distribution des élasticités autour de chaque point d'un solide,' *Liouville's Journal*, S. ii. t. viii. p. 257.

[3] See especially De St. Venant, 'Théorie des ondes lumineuses,' *Ann. de Chim.* S. iv. p. 22.

For an isotropic solid we should have $N_2' = N_3' = (\mu - 2L)\epsilon$ and $T_1' = 0$. Thus Green's medium in which the propagation of transverse waves is possible has properties which distinguish it from an isotropic solid, for a simple elongation produces on any plane parallel to the direction of the elongation a normal stress which depends on the position of the plane, while it also produces shearing stress about an axis parallel to the direction of the elongation; and although the theory does not explain double refraction satisfactorily, yet it is not open to De St. Venant's criticisms on this point.

§ 5 In the same paper St. Venant proposes a modification of Cauchy's theory which leads to Fresnel's wave surface without any more conditions than are required by Green; for, putting in Green's expression,

$$Al^2 + Bm^2 + Cn^2 = X \quad . \quad . \quad . \quad . \quad (3)$$

l, m, n being the direction cosines of the wave normal, the equation to determine the velocity becomes—

$$\begin{aligned}&\{\rho V^2 - X - Gl^2 - Hm^2 - In^2\}\left[(\rho V^2 - X)^2 - (\rho V^2 - X)\right.\\ &\qquad\left.\{(M+N)l^2 + (N+L)m^2 + (L+M)n^2\} + MNl^2 + NLm^2 + LMn^2\right]\\ &\quad - \{(H-L)(I-L) - (L+P)^2\}\ \{Gl^2 + Nm^2 + Mn^2 + X - \rho V^2\}m^2n^2\\ &\quad - \{(I-M)(G-M) - (M+Q)^2\}\ \{Nl^2 + Hm^2 + Ln^2 + X - \rho V^2\}n^2l^2\\ &\quad - \{(G-N)(H-N) - (N+R)^2\}\ \{Ml^2 + Lm^2 + In^2 + X - \rho V^2\}l^2m^2\\ &\quad + \{(G-M)(H-N)(I-L) + (G-N)(H-L)(I-M)\\ &\quad - 2(L+P)(M+Q)(N+R)\}l^2m^2n^2 = 0 \quad . \quad . \quad . \quad . \quad . \quad (4)\end{aligned}$$

And this will reduce to Fresnel's surface if $A = B = C$; that is, if the equilibrium stresses are equal, and the four conditions

$$\left.\begin{aligned}&(H-L)(I-L) = (L+P)^2\\ &(I-M)(G-M) = (M+Q)^2\\ &(G-N)(H-N) = (N+R)^2\\ &(G-M)(H-N)(I-L) + (G-N)(H-L)(I-M)\\ &\qquad\qquad - 2(L+P)(M+Q)(N+R) = 0\end{aligned}\right\} \quad . \quad (5)$$

are satisfied.

These equations include those of Green's first theory, and are approximately those which arise from what St. Venant calls an ellipsoidal distribution of elasticities. Under certain circumstances the tasinomic surface—which, it will be remembered, gives the tension in any direction produced by a simple elongation in that direction—reduces to an ellipsoid, and then the distribution of elastic constants is named by St. Venant ellipsoidal. This distribution is produced when an isotropic medium is unequally strained in three perpendicular directions. The theory is interesting, and important as showing that Fresnel's wave surface can be deduced from the general elastic solid theory on other assumptions as regards the constants than those given by Green, and that the vibrations in this case are not necessarily in the wave front. There will, however, in this case be a quasi-normal wave, the velocity of which is given by the equation

$$\rho V^2 - X - Gl^2 - Hm^2 - In^2 = 0;$$

and if Green's arguments as to the relative magnitude of the constants be still supposed to hold, the quasi-normal wave will disappear, and the vibrations will be very nearly indeed transversal. The theory, however, interesting as it is, does not enable us to overcome the difficulty of reconciling the theories of double refraction and reflexion so long as we adopt the view of Fresnel and Green, that the latter depends on difference of density, not of rigidity, in the two media. It is also open to the objection that if the medium be incompressible the displacements must be in the wave front, and we must get in this case Green's conditions, not the above; while if the medium be not incompressible an appreciable amount of energy must exist in the form of longitudinal vibrations.

§ 6. The question of the propagation of waves through an isotropic medium, which is rendered anisotropic by the production of three elongations, a, b, c, in three rectangular directions, has been studied by Boussinesq.[1] The elastic constants are taken to be linear functions of these permanent strains, and the number of constants involved in their expression is reduced from the considerations involved in the symmetry of the medium and the principle of the conservation of energy.

The equations of motion may be written

$$\left.\begin{aligned}\frac{d^2u}{dt^2} &= (\lambda+\lambda' a)\frac{d\theta}{dx} + (\mu+\rho a)\nabla^2 u \\ &+\sigma\left\{a\frac{d^2u}{dx^2}+b\frac{d^2u}{dy^2}+c\frac{d^2u}{dz^2}\right\} \\ &+\nu\frac{d}{dx}\left\{a\frac{du}{dx}+b\frac{dv}{dy}+c\frac{dw}{dz}\right\}\end{aligned}\right\} \quad . \quad . \quad . \quad (6)$$

with the condition implied by the principle of the conservation of energy that $\lambda'=\nu$, while if the normal stresses in the equilibrium condition vanish $\sigma=\rho$. These may be deduced from Green's equations by putting

$$\left.\begin{aligned}A=(\sigma-\rho)a,\quad B=(\sigma-\rho)b,\quad C=(\sigma-\rho)c,\\ G=\lambda+\mu+2(\rho+\nu)a,\\ L=\mu+\rho(b+c),\\ P=\lambda-\mu+(\nu-\rho)(b+c),\end{aligned}\right\} \quad . \quad . \quad (7)$$

with similar expressions for the other constants. λ and μ are the two elastic constants of the unstrained medium in the form in which they are written by Lamé, $\sqrt{\lambda}$ and $\sqrt{(\lambda+\mu)}$ being the velocities of transverse and normal waves respectively, the density being taken as unity.

It is thus shown that on the assumption that a, b, c are small quantities, such that their squares and products may be neglected, Fresnel's wave surface is given if either $\sigma=0$ or $\sigma=\rho$. In fact, the condition $\sigma=0$ leads to Fresnel's surface without any assumption as to the value of a, b, c, for then the theory becomes identical with Green's second theory; while if $\sigma=\rho$ we have either St. Venant's ellipsoidal condition or his suggested modification of Cauchy, for to this degree of approximation the two theories are identical.

[1] Boussinesq, *Liouville's Journal*, S. ii. t. viii.

We may conclude, then, that Fresnel's laws as to double refraction would hold in a medium strained in the manner Boussinesq considers, but the theory as a whole is liable to the same criticisms as have been made to Green's. Boussinesq is the author of another and different theory, which we shall consider later, and which gives a better explanation of the phenomena.

§ 7. This same problem has been dealt with by Professor C. Niven,[1] who has arrived at similar results without introducing considerations based on molecular reactions.

§ 8. The problem of double refraction has been treated in a different manner by M. Sarrau, following up the suggestions of Cauchy as to the nature of the ether in a crystal, and his theory is developed in two papers in 'Liouville's Journal.' In these papers[2] the density of the ether in a transparent medium is supposed to vary in a periodic manner from point to point. The ether is arranged in concentric shells of variable density round each matter molecule, and its density, variable round each matter molecule, is the same at any one of a series of points situated similarly with regard to the matter molecules. The ether is periodically homogeneous, and the coefficients which occur in the elasticity equations are no longer constant, but are periodic functions of the co-ordinates of the point whose displacement is being considered; from these equations are deduced a series of others with constant coefficients, containing the average displacements of the ether in an element of volume. It is to these average displacements that optical effects are supposed to be due.

Cauchy[3] has indicated the path to be followed in deducing these auxiliary equations from the fundamental forms, and M. Sarrau arrives at the following conclusion.

If the fundamental equations be represented by

$$\left.\begin{aligned} \frac{d^2u}{dt^2} &= \mathrm{F}\left(\frac{d}{dx'}\ \frac{d}{dy'}\ \frac{d}{dz'}\ u_1 v_1 w_1\right) \\ \frac{d^2v}{dt^2} &= \mathrm{G}\left(\ .\quad .\quad .\quad .\ \right) \\ \frac{d^2w}{dt^2} &= \mathrm{H}\left(\ .\quad .\quad .\quad .\ \right) \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad (8)$$

Where F, G, H are functions with periodic coefficients of u, v, w and their differential coefficients, then the auxiliary equations will be—

$$\left.\begin{aligned} \frac{d^2u}{dt^2} &= \mathrm{F}' + \mathrm{G}' + \mathrm{H}' \\ \frac{d^2v}{dt^2} &= \mathrm{F}'' + \mathrm{G}'' + \mathrm{H}'' \\ \frac{d^2w}{dt^2} &= \mathrm{F}''' + \mathrm{G}''' + \mathrm{H}''' \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad (9)$$

[1] C. Niven, *Quarterly Journal of Pure and Applied Mathematics*, No. 55, 1876.

[2] Sarrau, *C. R.* vol. lx. p. 1174. 'Sur la propagation et la polarisation de la lumière dans les cristaux,' *Liouville's Journal*, S. ii. t. xii. p. 1; t. xiii. p. 59.

[3] Cauchy, *Comptes Rendus*, t. xxx. p. 17.

F′, F″, F‴ being symbolic functions obtained by substituting integral functions of $\frac{d}{dx}, \frac{d}{dy}, \frac{d}{dz}$ for the periodic coefficients of F, and similarly for G′, H′.

The second memoir [1] is devoted to the consideration of the problem on the supposition that the ether in a crystal is isotropic as regards its elasticity, and that the variations in density are all which we have to consider. Again following Cauchy, and treating the ether as a system of attracting and repelling points, Sarrau arrives at the equations

$$\left.\frac{d^2u}{dt^2}=\mathrm{E}(\nabla^2)u+\mathrm{F}(\nabla^2)\frac{d\theta}{dx}\right\} \quad . \quad . \quad . \quad . \quad (10)$$

etc., where E and F are certain connected functions depending on the law of force, and θ the dilatation.

For free space—

$$\mathrm{E}(\nabla^2)=e\nabla^2,$$
$$\mathrm{F}(\nabla^2)=f,$$

e and f being constants.

For the ether in a crystal, omitting the consideration of dispersion, it is shown that it is probable that E and F have the same forms, only now e and f are periodic functions of the co-ordinates.

If we denote d/dx, d/dy, d/dz, d/dt by α, β, γ, σ, respectively, then the equations in the crystal become, in conformity with the general rule,

$$\sigma^2u=\nabla^2(\mathrm{F}_1u+\mathrm{F}_2v+\mathrm{F}_3w)+(f_1\alpha+f_2\beta+f_3\gamma)\theta,$$

etc., where F, G, H, etc., f, g, h, etc., denote now symbolic functions of α, β, γ.

These general equations are simplified by the consideration of the various kinds of symmetry possible, and it is shown that in the case of ordinary biaxial crystals they reduce to

$$\left.\begin{aligned}\frac{d^2u}{dt_2}&=f\nabla^2u+f_1\frac{d\theta}{dx}\\ \frac{d^2v}{dt^2}&=g\nabla^2v+g_1\frac{d\theta}{dy}\\ \frac{d^2w}{dt^2}&=h\nabla^2w+h_1\frac{d\theta}{dz}\end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (11)$$

It is further assumed that $f+f_1=g+g_1=h+h=0$. This, of course, is the condition that the velocity of the normal wave should be zero.

These equations are solved by putting $u=\mathrm{P}e^{k(lx+my+nz-\omega t)}$, etc., and lead to

$$\frac{\mathrm{P}}{\frac{fl}{\omega^2-f}}=\frac{\mathrm{Q}}{\frac{gm}{\omega^2-g}}=\frac{\mathrm{R}}{\frac{hn}{\omega^2-h}}=-(\mathrm{P}l+\mathrm{Q}m+\mathrm{R}n),$$

whence

$$\frac{l^2}{\omega^2-f}+\frac{m^2}{\omega^2-g}+\frac{n^2}{\omega^2-h}=0. \quad . \quad . \quad . \quad . \quad (12)$$

[1] *Liouville's Journal*, Ser. ii. t. xiii. p. 59.

Thus the wave surface is Fresnel's. The direction of vibration, the ray and the wave normal are shown to be in the same plane, but the direction of vibration is at right angles to the ray instead of to the wave normal.

The assumed conditions $f + f_1 = 0$, etc., form a serious objection to the theory as it stands, but on this point it is capable of modification. The vibrations, of course, are not strictly transversal within the crystal, but I am not aware of any experiments which prove that they must be so. Of course, if the medium be absolutely incompressible, the displacements must be in the wave front, and the theory fails; but the condition of stability and the evanescence of the longitudinal wave require merely that the incompressibility should be very great compared with the rigidity, without being absolutely infinite.

§ 9. M. Sarrau has considered the peculiar phenomena presented by quartz, and shows how on his theory the terms assumed by MacCullagh will arise.

For the crystalline symmetry of such a body, the equations are shown to take the form—

$$\left.\begin{aligned}\frac{d^2u}{dt^2}&=f\left(\nabla^2 u-\frac{d\theta}{dx}\right)+f_1\nabla^2\left(\frac{dw}{dy}-\frac{dv}{dz}\right)\\ \frac{d^2v}{dt^2}&=g\left(\nabla^2 v-\frac{d\theta}{dy}\right)+\nabla^2\left(g_1\frac{du}{dz}+g_2\frac{dw}{dx}\right)\\ \frac{d^2w}{dt^2}&=g\left(\nabla^2 w-\frac{d\theta}{dz}\right)+\nabla^2\left(g_1\frac{du}{dy}+g_2\frac{dv}{dx}\right)\end{aligned}\right\} \quad . \quad . \quad (13)$$

and it follows that two elliptically polarised waves can traverse the medium in any given direction.

The velocities of these waves are given by

$$\omega^2=g-\frac{1}{2}(g-f)\sin^2\theta \pm \frac{1}{2}\sqrt{\left\{(g-f)^2\sin^4\theta \right.}$$
$$\left. +\frac{16\pi^2}{\lambda^2}(g_2\cos^2\theta+f_1\sin^2\theta)\times(g_2\cos^2\theta-g_1\sin^2\theta)\right\} \quad . \quad (14)$$

f_1 and g_1 are two constants which are probably very small, and, in that case, the squares of the principal velocities at right angles to the axis are f and g, while the squares of the velocities parallel to the axis are given by

$$\omega^2=g\pm\frac{2\pi g_2}{\lambda}.$$

If ρ_1 represent the ratio of the axes of the ellipse in the ordinary wave, ρ_2 that in the extraordinary, then

$$\rho_1\rho_2=\frac{g_2\cos^2\theta-g_1\sin^2\theta}{g_2\cos^2\theta+f_1\sin^2\theta} \quad . \quad . \quad . \quad (15)$$

The major axis of the extraordinary ellipse is perpendicular to the principal plane, that of the ordinary ellipse is in the principal plane, while the two waves are polarised in opposite senses.

§ 10. De St. Venant[1] criticises the theory in the following points, ρ being the only periodic variable, the equations, he argues, should be treated as if the

[1] St. Venant, 'Sur les diverses manières de présenter la théorie des ondes lumineuses,' *Ann. de Chim.* (4), t. xxv. p. 335.

periodic coefficient was attached to the first term, $\rho \frac{d^2u}{dt^2}$, etc., and he states that the development of the equations $\rho \frac{d^2u}{dt_2} = \ldots$ leads to different results. Sarrau,[1] in reply, points out that this depends on the relative magnitudes of the quantities α, β, γ, σ^2, and the other parameters; on making the same suppositions in the two cases the results, he shows, are identical. One may, however, start from the general equations of an elastic solid with two coefficients, and, by supposing the coefficients to be periodic, arrive at the general equations already found.

M. de St. Venant finds a difficulty in explaining dispersion, for in an isotropic medium the periodicity of the coefficients vanishes. This may be true, and yet the equations contain differential coefficients above the second.

§ 11. The theory advanced by Von Lang[2] might perhaps more strictly be considered under the next section: 'Theories based on the mutual action between matter and the ether.' The theory is, however, so slight a modification of the ordinary elastic solid theory that it will be more convenient to deal with it now.

Von Lang supposes that the displacements which come into the ordinary elastic solid theory are displacements of the ether relative to the molecules of the matter. He assumes that the ratio of the matter displacement to that of the ether is in general a function of the direction, but that for three directions we may write

$$U = a^2u,\ V = b^2v,\ W = c^2w,$$

U, V, W being displacements of matter, u, v, w of ether.

He then forms the equations of motion, and, equating the velocity of the quasi-longitudinal wave to zero, arrives at Fresnel's wave surface. The theory cannot be regarded as having any real physical signification, for the elastic forces produced in the ether will depend on the real displacements of the ether particles, not on the displacements relatively to the matter, and the velocity of the normal wave cannot vanish, for if it does the medium becomes unstable.

§ 12. Von Lang[3] has also given a theory of circular polarisation, which consists in adding to the ordinary equations terms such as

$$\delta^2\left(\frac{dv}{dz} - \frac{dw}{dy}\right).$$

From this it follows that the velocity in a medium such as sugar is given by

$$\omega^2 = a^2 \pm \frac{\delta^2}{2\pi}\frac{V}{a}L,$$

L being the wave length in air; while in quartz

$$\omega^2 = a^2 - \frac{a^2 - c^2}{2}\sin^2\theta \pm \frac{1}{2}\sqrt{\left\{(a^2 - c^2)^2 \sin^4\theta + \frac{\delta^4\lambda^2}{\pi^2}\cos^4\theta\right\}} \quad . \quad (16)$$

[1] Sarrau, 'Observations relatives à l'analyse faite par M. de St. Venant,' *Ann. de Chim.* (4), t. xxvii. p. 266.
[2] Von Lang, 'Zur Theorie der Doppel-Brechung,' *Wied. Ann.* t. clix. p. 168.
[3] Von Lang, 'Zur Theorie der Circular-Polarisation,' *Pogg. Ann.* t. cxix. p. 74.

Von Lang holds that the experimental law connecting the rotation and the wave length is

$$\text{Rotation} = k + \frac{k'}{L^2} + \; . \; . \; . \; .$$

and this is given by the above expressions if

$$a^2 = m + \frac{n}{L^2} + \; . \; . \; . \; .$$

$$c^2 = m' + \frac{n'}{L^2} + \; . \; . \; . \; .$$

$$\delta^2 = rL + \frac{s}{L} + \; . \; . \; . \; .$$

No reason is given for assuming the form $\delta^2\left(\frac{dv}{dz} - \frac{dw}{dy}\right)$ rather than that selected by MacCullagh, $\delta^2\left(\frac{d^3v}{dz^3} - \frac{d^3w}{dy^3}\right)$, which leads to the correct relation between the rotation and the wave length without any violent supposition as to the form of δ^2, such as is made by Von Lang; and, though neither theory has any mechanical basis, this fact alone is sufficient to render MacCullagh's the more probable, while experiments on the size of the rings produced when convergent polarised light is transmitted through a plate of quartz cut at right angles to the axis agree rather better with MacCullagh's form than with Von Lang's.

§ 13. Another theory of double refraction was developed by Lord Rayleigh [1] in 1871. It had been suggested originally by Rankine,[2] and Stokes in his British Association Report referred to it, and showed that in its original form it was untenable. The theory is also given by Boussinesq in a paper in 'Liouville's Journal,' [3] which will be considered in full under the next section.

Lord Rayleigh points out the inconsistency already referred to between the theories of double refraction and reflexion given by both Green and Cauchy, while, as we shall see when considering the polarisation phenomena accompanying the reflexion, diffraction, and scattering of light, he believes that Neumann and MacCullagh, though consistent, were wrong throughout. He then remarks that the analogy of a solid moving in a fluid would suggest that the first effect of the matter molecules in a transparent body would be to alter the apparent density of the solid, and that conceivably this alteration might depend on the direction of vibration. He supposes that the statical properties of the ether are not altered by the presence of the matter, and the equations of motion may be written

$$\left.\begin{aligned} \rho_x \frac{d^2u}{dt^2} &= \frac{dp}{dx} + B\nabla^2 u \\ \rho_y \frac{d^2v}{dt^2} &= \frac{dp}{dy} + B\nabla^2 v \\ \rho_z \frac{d^2w}{dt^2} &= \frac{dp}{dz} + B\nabla^2 w \end{aligned}\right\} \quad . \quad . \quad . \quad (17)$$

where p is written for $A\delta$, δ being the dilatation.

[1] Hon. J. W. Strutt, 'On Double Refraction,' *Phil. Mag.* June 1871.
[2] Rankine, *Phil. Mag.* June, 1851. [3] See p. 215.

Lord Rayleigh further assumes the medium to be absolutely incompressible, so that δ is zero and A is infinitely large, p remaining finite; this, of course, leads to the fourth equation—

$$\frac{du}{dx}+\frac{dv}{dy}+\frac{dw}{dz}=0 \quad . \quad . \quad . \quad . \quad (18)$$

And from these equations the equation to the surface of wave slowness is shown to be

$$\frac{l^2}{\frac{V^2}{a^2}-1}+\frac{m^2}{\frac{V^2}{b^2}-1}+\frac{n^2}{\frac{V^2}{c^2}-1}=0 \quad . \quad . \quad (19)$$

This, however, is not Fresnel's surface, and experiments of a very high[1] degree of accuracy have shown that the wave surface in a crystal is very approximately indeed Fresnel's surface, and of course this is fatal. But, as we shall see in the next section, according to all the theories yet proposed based on the mutual reaction between matter and ether, the first and most important effect of the matter is to alter the apparent density of the ether in the way here supposed. The mutual reaction, it can be shown, will introduce terms of the form $k\frac{d^2u}{dt^2}$ into the equations, and k may conceivably depend on the direction.

§ 14. Equations of motion practically the same as Lord Rayleigh's are given by Boussinesq, Lommel, Ketteler, and Voigt, and the question arises, Are these equations incompatible with Fresnel's wave surface? Lord Rayleigh has, of course, proved that they are if the equation

$$\frac{du}{dx}+\frac{dv}{dy}+\frac{dw}{dz}=0$$

expresses an absolutely necessary condition; but it is not difficult to show that if, instead of the above equation, we put

$$\frac{1}{a^2}\frac{du}{dx}+\frac{1}{b^2}\frac{du}{dy}+\frac{1}{c^2}\frac{du}{dz}=0 \quad . \quad . \quad . \quad . \quad (20)$$

then the wave surface will be Fresnel's, the direction of vibration will be normal to the ray, and will be in the plane containing the ray, the wave normal, and an axis of the section of the ellipsoid $a^2x^2+b^2y^2+c^2z^2=1$ by the wave front, and while the velocity of propagation will be inversely proportional to the length of this axis.

Assuming equations of the same form as Lord Rayleigh's (17), we have to determine the pressural wave given by $p=p_0\epsilon^{i(lx+my+nz-Vt)}$ the equation

$$-\iota p_0=B\theta_0\left\{\lambda l\left(\frac{V^2}{a^2}-1\right)+\mu m\left(\frac{V^2}{b^2}-1\right)+\nu n\left(\frac{V^2}{c^2}-1\right)\right\},$$

where $$u=\lambda\theta_0\epsilon^{i(lx+my+nz-Vt)}, \text{ etc.,}$$

and this, on Lord Rayleigh's assumption of $l\lambda+m\mu+n\nu=0$, reduces to

$$p_0=\iota B\theta_0 V^2\left\{\frac{\lambda l}{a^2}+\frac{\mu m}{b^2}+\frac{\nu n}{c^2}\right\} \quad . \quad . \quad . \quad (21)$$

[1] See Stokes, *Proc. Roy. Soc.* vol. xx. p. 443; Abria, *Ann. de Chimie*; Glazebrook, *Phil. Trans.* Pt. I. 1879; Kohlrausch, *Wied. Ann.* t. vi. p. 86; t. vii. p. 427.

while, on the hypothesis suggested above, we should find

$$p_0 = -\iota B\theta_0\{\lambda l + \mu m + \nu n\} \quad . \quad . \quad . \quad . \quad (22)$$

The theory as here modified would, it appears to me, agree in its results with all the experimental facts; the main difficulty lies in the assumption of equations of the form $\frac{1}{a^2}\frac{d^2u}{dt} = \frac{1}{B}\frac{dp}{dx} + \nabla^2 u$ for the medium when it is not strictly incompressible. The value of p is generally $A\left(\frac{du}{dx} + \frac{dv}{dy} + \frac{dw}{dz}\right)$, and the introduction of p is based on the supposition that $\frac{du}{dx} + \frac{dv}{dy} + \frac{dw}{dz}$ is zero, and A infinite; it is questionable if the substitution ought to be made, except in this case.

§ 15. Kirchhoff's paper on double refraction [1] was read before the Royal Academy of Berlin, and is contained in their 'Transactions;' its more important part deals with the problem of reflexion and refraction. So far as the double refraction is concerned, it does not differ in any important points from Neumann's theory. The medium is supposed to be incompressible, so that $\frac{du}{dx} + \frac{dv}{dy} + \frac{dw}{dz}$ vanishes, but the coefficient of this expression is treated as finite, and the terms involving it in the expression for the energy are omitted. The criticisms on Neumann's theory, contained in Professor Stokes's report, apply again here.

Chapter II.—Dispersion of Light.

In 1870 Ketteler [2] published a paper on dispersion, which forms the first of his important series on that subject. He commences with an account of Cauchy's theory and the various modifications which have been proposed.

§ 1. Redtenbacker [3] had considered the problem under the supposition that each matter molecule is surrounded by an ether shell, and obtained the formula

$$\frac{1}{\mu^2} = a + \frac{b}{\lambda^2} + c\lambda^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad (23)$$

λ being the wave length in the medium, and μ the refractive index.

§ 2. Christoffel,[4] discussing Cauchy's formula, already mentioned,[5] viz.

$$\frac{1}{\mu^2} = a + \frac{b}{\lambda^2} + \quad . \quad . \quad . \quad .$$

had shown that, while a and b may be considerable in value, the other constants decrease rapidly. This two-constant formula may be written—

$$\mu = \frac{\mu_0\sqrt{2}}{\sqrt{\left(1 + \frac{\lambda_0}{\lambda}\right)} + \sqrt{\left(1 - \frac{\lambda_0}{\lambda}\right)}} \quad . \quad . \quad . \quad (24)$$

[1] Kirchhoff, *Abhandl. der Königl. Akad. zu Berlin*, 1876.

[2] Ketteler, 'On the Influence of Ponderable Molecules on the Dispersion of Light, and the Signification of the Constants of the Dispersion Formulæ,' *Pogg. Ann.* t. cxl. p. 1.

[3] Redtenbacker, *Dynamiden-System*, Mannheim, 1857.

[4] Christoffel, *Pogg. Ann.* t. cxvii.

[5] See p. 165.

Thus μ_0 and λ_0 are the refractive index and wave length for the shortest waves transmitted, and $\mu_0\sqrt{2}$ the refractive index for the largest possible waves.

§ 3. The various theories are then compared with experiment, by Ketteler, and it is shown that the formula

$$\frac{1}{\mu^2} = \mathrm{K}\lambda^2 + \mathrm{A} + \frac{\mathrm{B}}{\lambda^2} + \frac{\mathrm{C}}{\lambda^4} \quad . \quad . \quad . \quad . \quad (25)$$

represents the results of the comparison most accurately. This formula was obtained by Briot, working on the same lines as Redtenbacker, but he supposes the coefficient K, which he shows depends on the direct action between matter and ether, to vanish. Van der Willigen [1] also called attention to the importance of the term in λ^2, but could not account for its existence. Ketteler, following Briot, then analyses the manner in which these various terms arise, and shows that the force on any vibrating ether particle may be written

$$\frac{4\pi^2}{\lambda^2}\left\{\text{Displacement of particle}\right\}$$
$$\times\left\{(g+h)(1-\mathrm{L}) - \frac{4\pi^2}{\lambda^2}\mathrm{M} + \frac{g_1+h_1}{4\pi^2}\lambda^2\right\}.$$

This, of course, gives

$$\frac{1}{\mu^2} = \mathrm{A} + \frac{\mathrm{B}}{\lambda^2} + \mathrm{K}\lambda^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad (26)$$

The term in $g+h$ arises from the mutual reactions of the ether particles, supposed to be uniformly distributed. If the action of the matter be simply to produce a periodic variation in the density of the ether, the terms in L and M are introduced, while the term involving g_1+h_1 comes from a direct force expressed by $mm_1rf_1(r)$ between the ether and matter particles m and m_1 respectively. If we put $rf_1(r) = \mu/r^n$, then the value of g_1+h_1 is $-\frac{1}{3}(n-2)\Sigma m_1\mu/r^{n+1}$.

Briot supposes that the term $\mathrm{K}\lambda^2$, to which this gives rise, is not required by the experimental results, and therefore puts $n=2$. Ketteler, however, shows that this term must be included.

Holtzmann and C. Neumann had already insisted on the importance of retaining in the equations terms to express this direct action, and Neumann gives as the expression in an isotropic medium for the force arising from a displacement u,

$$\mathrm{C}u + \mathrm{C}'\frac{d^2u}{dz^2} + \mathrm{C}''\frac{d^4u}{dz^4}.$$

But the theory of dispersion in its complete form requires that the motion of the matter particles should also be included. This is treated of in the next section of the Report.[2]

A problem closely connected with dispersion is the relation between the refractive index and the density of a medium. This has been dealt with experimentally by various physicists, notably by Gladstone and Dale in England, and Ketteler in Germany.

§ 4. L. Lorenz [3] has recently developed the theory of the transmission

[1] Van der Willigen, *Archives du Musée Teyler.* [2] See p. 213, etc.

[3] L. Lorenz, 'On the Refraction Constant,' *Wied. Ann.* t. xi.

of light through a medium consisting of a series of small spheres imbedded in the ether. The velocity of light in the interspaces is the same as in free space, and the wave length is supposed to be great compared with the intermolecular distances. It is assumed, then, that the disturbance u at any point may be written $u=(u_0+u_2)C+u_1S$, where the average values of u_1 and u_2 over the space containing some considerable number of molecules are zero, and C and S are written for the sine and cosine of $kt-lx-my-nz-\delta$. From this it follows that, if μ be the refractive index and d the density, $\frac{\mu^2-1}{\mu^2+2}$ is proportional to d.*

The paper is followed by one by Lorenz and K. Prytz, giving the results of an elaborate series of observations which show a close agreement between this expression and experiment.

Chapter III.—Aberration and Phenomena connected with the Motion of the Medium through which Light is being propagated.

§ 1. The aberration of light on the undulatory theory was accounted for by Fresnel[1] on the supposition that a moving body of refractive index μ carries with it a quantity of ether of density μ^2-1, the density in a vacuum being unity, while light is propagated through this ether, part of which is at rest and part moving with a velocity v (that of the body), as if the whole were moving with the velocity $(1-\mu^{-2})v$.

The experiments of Fizeau[2] on the displacement of the fringes of interference by a moving medium led to a result in close accordance with this theory.

§ 2. A more general and simpler proof than the one published by Fresnel of the fact that this leads to the ordinary laws of reflexion and refraction was given by Professor Stokes in 1846.[3]

In this paper Professor Stokes points out that the same result as to the velocity of light in the medium will be arrived at if we suppose the ether on entering the medium to be condensed, and on leaving it to be rarified, while the whole ether in the body travels with the velocity given above; for, if we take two planes, one outside the other inside the medium, each moving with the velocity v normal to itself, the quantity of ether which crosses the two planes per unit time will be the same, and hence, if V be the velocity of the ether in the medium, then we have, since the densities are 1 and μ^2 respectively,

$$v=\mu^2(v-V),$$

and hence

$$V=\frac{\mu^2-1}{\mu^2}v.$$

Moreover, this comes to the same thing as supposing the medium to be at rest, while the ether outside moves with a velocity v, and that inside with a velocity v/μ^2. The direction of a ray is shown to be that in which the same portion of a wave moves, moving relatively to the medium, and is found by drawing from a given point a line of length V/μ in a direction

* Compare this with a similar paper by H. A. Lorenz, p. 255.

[1] Fresnel, *Annales de Chimie*, t. ix. p. 57.

[2] Fizeau, *Annales de Chimie* (3), t. lvii. p. 385.

[3] Stokes, 'On Fresnel's Theory of the Aberration of Light,' *Phil. Mag.* vol. xxviii. p. 76; *Mathematical Papers*, vol. i. p. 141.

normal to the wave, and from the extremity of this line a second of length v/μ^2 in the direction of motion of the ether; the ray is the line joining the first point to the extremity of this second line. The velocity of the ether is resolved into its components perpendicular and parallel to the reflecting surface, and the effect of each component is considered; it is shown that rays are reflected and refracted according to the ordinary law of sines.

§ 3. But in a paper six months previously Professor Stokes[1] had considered the problem in a much more general manner. He supposes that the earth and planets carry with them a portion of the ether surrounding them, so that close to their surfaces the ether is relatively at rest, while the velocity alters as we recede from the surfaces until, at no great distance, it is at rest in space.

The direction in which a body is seen is normal to the waves which have reached the observer from the body, and the change in this apparent direction which arises from the motion of the ether is investigated.

The axis of z is taken in the direction of the normal to the undisturbed wave, and α, β, γ are the angles which the normal to the actual wave makes with the axes; u, v, w are the velocities of the ether at a point x, y, z at time t; V the velocity of light. The equation to the wave is

$$z = \mathrm{C} + \mathrm{V}t + \zeta,$$

ζ being a small function of x, y and t.

Then, by considering the displacement of the extremity of an element $\mathrm{V}\delta t$, drawn normal to the wave, it is shown that at time $t+\delta t$ the equation is

$$z = \mathrm{C} + \mathrm{V}t + \zeta + (w + \mathrm{V})\, dt,$$

and hence we see that

$$\frac{d\zeta}{dt} = w.$$

From this we find—

$$\alpha = \frac{\pi}{2} + \frac{1}{\mathrm{V}}\int \frac{dw}{dx}\, dz, \quad \beta = \frac{\pi}{2} + \frac{1}{\mathrm{V}}\int \frac{dw}{dy}\, dz.$$

If now

$$\frac{dw}{dx} = \frac{du}{dz}, \quad \frac{dw}{dy} = \frac{dv}{dz},$$

so that $udx + vdy + wdz$ is a complete differential, then

$$\alpha_2 - \alpha_1 = \frac{u_2 - u_1}{\mathrm{V}}, \quad \beta_2 - \beta_1 = \frac{v_2 - v_1}{\mathrm{V}}$$

and these equations, it is easily seen, imply the known law of aberration.

In an additional note it is shown that if α_1, β_1 be the inclinations of a ray at any time to the axes, then

$$\left.\begin{aligned} d\alpha_1 &= \left(\frac{du}{dz} - \frac{dw}{dx}\right) dt \\ d\beta_1 &= \left(\frac{dv}{dz} - \frac{dw}{dy}\right) dt \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (27)$$

[1] Stokes, 'On the Aberration of Light,' *Phil. Mag.* vol. xxvii. p. 9 (July, 1845); *Mathematical Papers*, vol. i. p. 134.

So that, if $udx + vdy + wdz$ be a complete differential, $d\alpha_1$ and $d\beta_1$ both vanish, and the path of the ray is a straight line.

Thus, if the motion of the ether produced by the passage of the transparent medium through it have a velocity potential, all the phenomena of aberration will be such as are actually observed. The important question as to whether such a motion is probable in the ether is discussed in another paper.[1]

§ 4. Professor Stokes's views on the constitution of the ether are given in his well-known paper on fluid friction.[2] He distinguishes there between the properties of rigidity and plasticity, pointing out that an elastic solid may under different external conditions become a viscous fluid, while the gradation between viscous and perfect fluids is quite regular. There seems, then, a probability that the property of rigidity will run to some extent through the whole series, becoming, in the case of fluids, masked by some other more important property. The mobility of a fluid is the limiting case of great plasticity; but even a perfect fluid may admit of a finite, though extremely small, amount of constraint of the nature of shearing stress before being relieved from its state of strain by its molecules assuming new positions of equilibrium. A consideration of the length of a wave in light motion—about ·00003 inches—renders it probable that 'the relative displacement of the ether particles may be so small as not to reach, or even come near, the greatest relative displacement which could exist without the molecules of the medium assuming new positions of equilibrium.'

These same views also tend to confirm the belief that for fluids, and among them the ether, the ratio of A to B (the elastic constants of the medium in Green's notation) will be extremely great.

We are led, then, to conclude that, in considering the motion set up in the ether by a moving body such as the earth, we may treat the ether as an incompressible fluid, while, on the other hand, when dealing with the extremely small disturbance produced by the passage of a light-wave the rigidity of the ether may come into consideration, and the equations required will be those of an elastic solid. In the first case any tangential forces which may arise, if the fluidity be not perfect, will depend on the relative velocities of the parts of the fluid; in the second case such tangential forces will depend on the relative displacements of those parts. In the paper in the 'Philosophical Magazine' for 1846 Professor Stokes shows that it is probable that a velocity potential will exist unless the action of the air on the ether be such as to prevent it, and, further, that it is improbable that the air will so act.

For suppose a sphere started from rest in such a medium, and then after a short interval stopped for a time, then started, and so on.

The initial motion will have a velocity potential, and if the fluid were perfect this would continue, so that reducing the sphere to rest would stop the motion everywhere. But the motion with the velocity potential is shown to be unstable, and hence there is left in the neighbourhood of the sphere a small outstanding disturbance. This is carried

[1] Stokes, 'On the Constitution of the Luminiferous Ether viewed with reference to the Phenomenon of the Aberration of Light,' *Phil. Mag.* vol. xxix. p. 6; *Math. and Phys. Papers*, i. p. 153.

[2] Stokes, 'On the Theories of the Internal Friction of Fluids in Motion, and the Equilibrium and Motion of Elastic Solids,' *Trans. Camb. Phil. Soc.* vol. viii. p. 287; *Math. and Phys. Papers*, i. p. 75.

off with the velocity of light, which is about 10,000 times as great as that of the earth, so that at the end of the second interval the ether near the sphere is at rest again and the same effect is repeated. It seems, therefore, probable that there will be a tendency to set up a motion in the ether not having a velocity potential, but that the beginnings of such motion will be propagated away into space at a very great rate, and that the actual motion will satisfy the condition that $udx+vdy+wdz$ is an exact differential.

In a subsequent paper Professor Stokes gives the solution of the equations of motion of a sphere moving in a viscous fluid, and then proves that when the fluid becomes perfect the motion becomes unstable, so that $udx+vdy+wdz$ is not a complete differential; but if the tangential force depends, not on the relative velocities, but on the relative displacements of the molecules—that is, if for the beginnings of the variation from irrotational motion we must consider the rigidity of the ether (*i.e.*, in our mathematics use the equations of an elastic solid)—then, as shown already, this nascent variation from irrotational motion will be propagated away by transverse vibrations, which, however, do not produce optical effects, either because they are too feeble or because they are discontinuous, or, if continuous, because their period falls outside that of the visible spectrum.

Or, to put it slightly differently, if the fluid has any very slight rigidity, a given arrangement of its parts is not necessarily one of equilibrium. Suppose, then, the fluid displaced from rest by the sudden motion of the solid, and that after a short interval the solid is stopped, the velocity of the fluid will be reduced everywhere to zero, but the resulting configuration will not necessarily be one of equilibrium, and the motion arising from this slight strain will be set up.

Thus, without making Fresnel's somewhat violent assumptions as to the relation between the ether within and without a transparent body, a perfectly reasonable and consistent account can be given of aberration depending only on the irrotational character of the motion induced by the moving body in the surrounding fluid. Unfortunately, as Professor Stokes points out, we have as yet no experiments competent to decide between the two, and he does not see how such experiments could be devised.

§ 5. Ketteler is the author of a long series of papers connected with the subject of aberration, which have appeared in Poggendorff's 'Annalen.' The last of these[1] contains a summary of the results of the whole. The problem of reflexion and refraction at a moving surface is considered, and it is shown that the intensities of the reflected and refracted rays will not be modified by the motion if the vibrations be at right angles to the plane of polarisation, as Fresnel supposed.

§ 6. The papers also deal with the problem of the emission of light from a moving source, and the principle first enunciated by Doppler,[2] in consequence of which it follows that if the source and receptacle approach each other in time t by a space equal to n times the wave length in the medium between the two, then the receptacle receives in that time n more vibrations than it would if the two were relatively at rest; and if this number be N, the apparent frequency is increased in the ratio $\mathrm{N}+n$

[1] Ketteler, 'Ueber den Einfluss der astronomischen Bewegungen auf die optisch n Erscheinungen,' Pt. VI., *Pogg. Ann.* t. cxlvii.

[2] Doppler, *Das farbige Licht der Doppel-Sterne.* 1842.

to N, or if V be the velocity of light, v that of the source towards the receptacle, in the ratio $V+v$ to V.

This principle has been considered by other writers, among them Petzval, Von Ettingshausen, Klinkerfuess,[1] Van der Willigen,[2] and Secchi,[3] and an interesting discussion of their work has been lately given by H. H. Turner, in a dissertation for a fellowship at Trinity College, Cambridge.

Chapter IV.—Reflexion and Refraction.

§ 1. The various theories of reflexion and refraction advanced by Fresnel, Green, MacCullagh, Neumann, and Cauchy have been discussed by several writers, and attempts have been made to reconcile them with the experiments of Jamin, Quincke, and others. Jamin was the first to show that by reflexion at most transparent media plane polarised light becomes elliptically polarised, and that this elliptic polarisation is most marked when the angle of incidence does not differ much from $\tan^{-1}\mu$. Moreover, for some substances for which the refractive index is greater than 1·4 the phase of the component in the plane of incidence is retarded relatively to that at right angles to the plane, while if the index be less than 1·4 the reverse is the case.

The original theories of Fresnel and MacCullagh do not in any way explain this phenomenon, and are therefore incomplete.

§ 2. Cornu[4] has discussed the application of Fresnel's theory to crystals, and has suggested a means of explaining the apparent discontinuity of the displacement normal to the surface to which that theory leads. The explanation—which Professor Stokes has been in the habit of giving, independently of Cornu, in his lectures at Cambridge—rests on the fact that the density of the ether is different in the two media. If, then, we take two planes in the two media parallel to the interface and at a small distance apart, the quantity of ether between the two planes remains the same; hence, if u, u' be the displacements normal to the planes, and ρ, ρ' the densities, the equation of continuity gives $\rho u = \rho' u'$, and this is the condition assumed by Cornu in his papers. This condition, combined with those of the continuity of the displacement parallel to the surface, is consistent with the equation expressing the conservation of energy.

The correctness of this condition depends on the view we take of the ether in the two contiguous media. If the two portions of ether be treated as two separate elastic solids in contact over a common surface, then over that surface the displacement must be the same in the two media; but the equality of the displacement normal to the surface cannot extend beyond a very small distance within the medium, and in the displacement is included that which comes from the pressural wave, as well as that which produces light. During the motion, of course, the bounding surface of the two media does not remain plane, but is a curved surface, the co-ordinates of any point on which at time t are u, $v+y$, $w+z$.

[1] Klinkerfuess, *Astronomische Nachrichten*, t. lxv. p. 17, t. lxvi. p. 337.

[2] Van der Willigen, *Archives du Musée Teyler*, t. iii. p. 306.

[3] Secchi, *C. R.* t. lxxxii. p. 761, t. lxxxiii. p. 117.

[4] Cornu, 'Recherches sur la réflexion crystalline,' *Ann. de Chim.* (4), t. xi. p. 283.

The condition of no dilatation holds throughout both media, and the stresses over the surface are the same in the two.

According to this view, a small portion of ether which belongs to one of the two media remains of unchanged density, and always forms part of the same medium.

We may, however, consider the question somewhat differently, and look upon the ether in the two media as continuous, but of different densities on the two sides of the interface. A portion of ether belonging to the first medium may cross the interface and become part of the second, and in so doing its density is changed. There will thus be a thin sheet of ether lying over the interface in which rapid periodic changes of density are occurring.

If, then, we consider the motion on the two sides of the sheet, we have for its determination the fact that the quantity of matter within the sheet is constant, and therefore that $\rho u = \rho' u'$, while the motion parallel to this sheet will ultimately be the same in the two media, and the energy in the reflected and refracted waves will be equal to that in the incident. But this condition $\rho u = \rho' u'$ does not hold within the sheet where the variations of density are taking place, and where the effects of the pressural wave are appreciable. The motions denoted by u and u' are light-motions, exclusive of those which give rise solely to the pressural wave. Moreover, it is supposed that this layer of variable density is so thin that the phase of the disturbance may be treated as the same over its two bounding surfaces. It is further assumed that the above are the only conditions which hold at the surface, and these can be satisfied without supposing any change of phase to arise from the reflexion. As a fact, there are other conditions involved in the equality of the stresses over the surface, and to satisfy these it is necessary to suppose that when the vibrations are in the plane of incidence the phases of the incident reflected and refracted waves differ even at the surface.

To assume Fresnel's conditions, as is done by Cornu, without change of phase is equivalent to supposing that this sheet of variable density is indefinitely thin when compared with the wave length of light.

Green himself considered the effect of supposing the change in refractive index to take place in a gradual manner, replacing the refracting surface by a regular series of layers, of indices μ_1, μ_2, etc., each of thickness τ; and proved that the effect of such a series would be to make the intensity of the reflected wave more nearly that given by Fresnel's tangent formula.

The effects of supposing the change of properties from one medium to the other to be gradual was discussed by L. Lorenz in the year 1860.

§ 3. In his first paper [1] he supposes that Fresnel's formulæ express the result of a sudden transition, and investigates how they must be modified if the transition be gradual. The variable sheet is divided into a series of layers, each of constant density. A ray reflected at one of the interior layers will on emergence be retarded relatively to the ray reflected at the surface. Let δ be the retardation of the ray reflected at a layer on which the angle of incidence is x, and let α, β be the angles of incidence and emergence, then the disturbances in the reflected ray are shown to be :—

[1] L. Lorenz, 'On the Reflexion of Light at the Bounding Surface of two Isotropic Media,' *Pogg. Ann.* t. cxi. p. 460.

(1) Light polarised in the plane of incidence—

$$R = A\frac{\sin(a-\beta)}{\sin(a+\beta)}\Big[\cos kt + \tan\triangle \sin kt\Big] \quad . \quad . \quad (28)$$

where

$$\tan\triangle = \frac{\sin a\cos a}{\sin^2 a - \sin^2\beta}\int_a^\beta\Big(\cos^2\beta\tan x - \sin^2\beta\cot x\Big)\frac{d\delta}{dx}dx \quad . \quad (29)$$

(2) Light polarised at right angles to the plane of incidence—

$$R' = -A'\frac{\tan(a-\beta)}{\tan(a+\beta)}\Big[\cos kt + \tan\triangle'\sin kt\Big] \quad . \quad (30)$$

where

$$\tan\triangle' = \frac{\sin 2a\sin 2\beta}{\sin^2 2a - \sin^2 2\beta}\int_a^\beta\Big[\frac{\sin 2x}{\sin 2\beta} - \frac{\sin 2\beta}{\sin 2x}\Big]\frac{d\delta}{dx}dx \quad . \quad (31)$$

Now $\frac{d\delta}{dx}$ is always small, hence $\triangle$ is small; but for $\sin 2a = \sin 2\beta$, or $\tan a = \mu$, $\tan\triangle'$ is infinite.

Jamin's results as to positive and negative reflexion are shown to follow, and if it be assumed that the density is approximately proportional to μ^2-1, the thickness of the variable sheet can be estimated, and is found to lie between $\frac{1}{10}$ and $\frac{1}{100}$ of the wave length.

In criticising this theory, Lord Rayleigh, in a paper we shall shortly consider, has pointed out that Fresnel's tangent formula does not express the result of sudden transition, and that Green's formula, which does, deviates from the truth on the other side. On the electro-magnetic theory, however, the tangent formula is strictly true, and Lorenz's investigations regain their interest.

Another objection which Lord Rayleigh has made to the supposition of gradual transition, however, may be a serious one. It is that there should be some indication of colour in the light reflected near the polarising angle, since it is to all intents and purposes a case of interference produced by a thin plate. It may, however, happen that the thickness of the plate is comparable with that of the black spot in Newton's rings, and so, though big enough to modify the quantity of light reflected, is too small to show colour. According to Newton, the thickness of the black spot in a soap film is about $\frac{1}{20}$ of a wave length, while Reinold and Rücker have recently determined it as $\frac{1}{50}$, and these fall within the limits required by Lorenz to explain the variations from Fresnel's tangent formula.

In another paper [1] the problem of reflexion at a surface across which the density varies gradually has been more fully considered by Lorenz, and the surface conditions on either side of the variable layer are deduced according to a strict elastic solid theory, and lead to similar conclusions.

§ 4. Cauchy gave the results of his theory of reflexion and refraction without the calculations which were supplied by Briot [2] in France, and Beer [3] and Eisenlohr [4] in Germany.

[1] L. Lorenz, *Pogg. Ann.* t. cxiv. p. 238.
[2] Briot, *Liouville's Journal*, t. xi. p. 305; t. xii. p. 185.
[3] Beer, *Pogg. Ann.* t. xci. and xcii.
[4] Eisenlohr, *Pogg. Ann.* t. civ. p. 346.

An account of the various theories is also given in papers by Lord Rayleigh,[1] with a careful criticism and comparison of them all.

In the first part of this paper Lord Rayleigh discusses fully the difference between the theories of Green and MacCullagh, and develops completely the consequences of the latter, taking into account the full effect of the pressural wave. This had been done first by Lorenz in the paper already referred to, and he showed that the results to which MacCullagh's theory leads are totally inconsistent with experiment.

Lord Rayleigh points out that the fundamental assumptions of Green and Fresnel amount to assuming an identity between the statical properties of the two media, while the dynamical properties depending on variation of density are different; while, moreover, as we have seen already, Cauchy's surface conditions, founded on the principle of the continuity of the displacements and their differential coefficients with reference to the normal, though erroneous if we suppose the rigidity of the ether different in the two media, become identical with Green's if we adopt his fundamental hypothesis. The real difference between Green and Cauchy lies in their respective treatments of the pressural waves.

The true surface conditions lead to the following results:—

Let ξ, η, ζ be the displacements, n the rigidity, m the second coefficient, such that $m+n$ is the A of Green's papers, and D the density, while $g^2 = (m+n)/\mathrm{D}$, $\gamma^2 = n/\mathrm{D}$ for the one medium.

Let $x=0$ be the bounding surface, and let the axis of z be parallel to the front of the waves. And suppose f, F, and f_1 to represent the incident reflected and refracted waves, while ϕ and ϕ' are the angles of incidence and refraction.

Then, for vibrations normal to the plane of incidence—

$$\frac{\mathrm{F}'}{f'} = \left.\frac{\dfrac{\tan\phi'}{\tan\phi} - \dfrac{n'}{n}}{\dfrac{\tan\phi'}{\tan\phi} + \dfrac{n'}{n}}\right\} \quad . \quad . \quad . \quad . \quad . \quad (32)$$

and this becomes:—

CASE I. $n = n'$ (Green, Fresnel, Cauchy)—

$$\frac{\mathrm{F}'}{f'} = \frac{\sin(\phi' - \phi)}{\sin(\phi' + \phi)} \quad . \quad . \quad . \quad . \quad . \quad (33)$$

CASE II. $\mathrm{D} = \mathrm{D}'$ (MacCullagh, Neumann)—

$$\frac{\mathrm{F}'}{f'} = \frac{\tan(\phi' - \phi)}{\tan(\phi' + \phi)} \quad . \quad . \quad . \quad . \quad . \quad (34)$$

Now, Jamin, Quincke, and others have shown that this latter formula is not strictly true, and hence at this point the evidence is already in favour of Fresnel's hypothesis.

Turning now to the case of the vibrations in the plane of incidence, put

$$\xi = \frac{d\Phi}{dx} + \frac{d\Psi}{dy},$$

$$\eta = \frac{d\Phi}{dy} - \frac{d\Psi}{dx}.$$

[1] J. W. Strutt, 'On the Reflexion of Light from Transparent Matter,' *Phil. Mag.* August, 1871; 'On the Reflexion and Refraction of Light by Intensely Opaque Matter,' *Phil. Mag.* May, 1872.

Then Ψ refers to the light wave and Φ to the pressural wave; let Ψ' refer to the incident wave, Ψ'' to the reflected, Ψ_1 to the refracted, so that

$$\Psi = \Psi' e^{i(ax+by+ct)} + \Psi'' e^{i(-ax+by+ct)},$$

etc. Then the surface conditions become in general, if we put

$$\Psi' + \Psi'' = X, \qquad \Psi' - \Psi'' = Y.$$

$$\left.\begin{aligned} i(\Phi + \Phi_1) &= \Psi_1 - X \\ b(\Phi - \Phi_1) &= aY - a_1\Psi_1 \end{aligned}\right\} \quad . \quad . \quad . \quad (35)$$

$$\begin{aligned}\Phi\{m(a'^2 + b^2) - 2nb^2\} &+ 2nabY \\ &= \Phi_1\{m'(a_1'^2 + b^2) - 2n'b^2\} + 2n'a_1b\Psi_1 \quad . \quad . \quad (36)\end{aligned}$$

$$\begin{aligned}n\{b^2\Psi_1 - a^2X &+ ib(aY - a_1\Psi_1)\} \\ &= n'\{b^2X - a_1{}^2\Psi_1 + ib(aY - a_1\Psi_1)\} \quad . \quad . \quad (37)\end{aligned}$$

MacCullagh, in his original work, neglects the pressural waves entirely, and puts $\Phi = \Phi_1 = 0$, deriving his result (Fresnel's sine formula) from equation (35). These results are inconsistent with (36) and (37), and therefore wrong. To obtain the correct solution we must remember that m is infinitely great, while $a'^2 + b^2$ is vanishingly small, and $m(a'^2+b^2) = Dc^2$. This is what has been done by Green, and applied by Lorenz and Lord Rayleigh to MacCullagh's theory.

[Cauchy puts $a'^2 + b^2 = -k^2$. We shall consider the consequences of this shortly.]

Hence (36) becomes

$$D\Phi - D'\Phi_1 = \frac{b^2}{c^2}(n - n')\left\{\frac{\Psi_1 - X}{i} - \frac{Ya + a_1\Psi_1}{b}\right\} \quad . \quad (38)$$

CASE I. $n = n'$ (Green).

Then

$$R' = R\frac{\tan(\phi - \phi')}{\tan(\phi + \phi')}\left\{\frac{1 + M^2\tan^2(\phi + \phi')}{1 + M^2\tan^2(\phi - \phi')}\right\}^{\frac{1}{2}} \quad . \quad . \quad (39)$$

R' and R being the amplitudes of the reflected and refracted waves, and M equal to $\dfrac{\mu^2 - 1}{\mu^2 + 1}$, while the difference of phase between the incident and refracted waves is e where

$$\cot e = \frac{1}{M}\cot(\phi - \phi') \quad . \quad . \quad . \quad . \quad (40)$$

while between the reflected and refracted waves it is e', where

$$\cot e' = \frac{1}{M}\cot(\phi + \phi') \quad . \quad . \quad . \quad . \quad (41)$$

CASE II. $D = D'$ (MacCullagh's corrected theory).

The equations are very complicated and lead, when the difference in the rigidities is very small, to two polarising angles of $22\frac{1}{2}°$ and $67\frac{1}{2}°$ respectively, results which are thus utterly at variance with experiments.

Cauchy's theory leads to results the same in form as Green's, if we substitute $-\epsilon\sin\phi$ for M, ϵ being a certain small constant.

The solution is contained in the above equations if we take

$$a'^2 + b^2 = -k^2, \qquad a_1'^2 + b^2 = -k_1{}^2,$$

and put

$$\frac{2\pi}{\lambda}\left(\frac{1}{k}-\frac{1}{k_1}\right)=-\epsilon \quad . \quad . \quad . \quad . \quad . \quad (42)$$

In Eisenlohr's account of Cauchy's work it is assumed at first that the normal waves travel with the same velocity as the transverse, and then the solution is modified by putting for $\lambda_{,,}$, λ'', the wave lengths of the normal waves, the values $-l_{,,}\sqrt{-1}$ and $-l''\sqrt{-1}$. This modifies $\phi_{,,}$ and ϕ'', the angles of refraction and reflexion of the normal waves, so that their sines become imaginary, while $\cos\phi_{,,}$ is real and negative, $\cos\phi''$ real and positive.

A difference of phase is thus produced, determined by the following equations:—

$$\tan e = p\tan(\phi-\phi'),$$

$$\tan e' = p\tan(\phi+\phi'),$$

where

$$p=\frac{m''-m_{,,}}{m''m_{,,}-1},$$

and

$$m_{,,}=\sqrt{\left(1+\frac{\lambda^2}{\lambda_{,,}^2\sin^2\phi}\right)},$$

$$m''=\sqrt{\left(1+\frac{\lambda^2}{\lambda''^2\sin^2\phi}\right)}.$$

Jamin's results show that p is very small; hence we may write

$$\frac{\lambda}{l_{,,}}=t+u,\ \frac{\lambda}{l''}=t-u,$$

where u is small, and then

$$p=\frac{2u\sin\phi}{t\sqrt{(t^2+\sin^2\phi)}} \quad . \quad . \quad . \quad . \quad (43)$$

Cauchy puts $p=\epsilon\sin\phi$, when ϵ is a small constant. Hence we must suppose that t is great compared with ϕ.

Lorenz and Lord Rayleigh have both pointed out the serious objection to be made to the theory in this form. The equation to determine Φ is $\frac{d^2\Phi}{dx^2}+\frac{d^2\Phi}{dy^2}=-\frac{k^2}{c^2}\frac{d^2\Phi}{dt^2}$, and the medium will be essentially unstable. Moreover, if k be a constant, ϵ varies inversely as λ, and chromatic effects near the polarising angle should be much more marked than they are.

I have, however, given an account of Eisenlohr's paper mainly because of another suggestion he makes, which renders it very nearly identical with Green's. He suggests that the normal or pressural waves may vanish 'by a sort of total reflexion, their velocity being very great compared with that of the transverse waves.' So that we have $\lambda_{,,}$ and λ'' very large instead of imaginary, and from this he finds

$$p=\frac{\lambda_{,,}^2-\lambda''^2}{\lambda_{,,}^2+\lambda''^2} \quad . \quad . \quad . \quad . \quad . \quad (44)$$

This vanishing by a sort of total reflexion is exactly Green's theory, for

if χ' be the angle of refraction for a normal wave produced by a transverse wave incident at an angle ϕ, then, with the notation of Lord Rayleigh's paper, $n \sin^2 \chi = m \sin^2 \phi$, and hence χ is imaginary unless ϕ is less than $\sin^{-1}(n/m)$. That is to say, if m be infinitely large, the effects of the pressural wave are entirely confined to the surface, and, indeed, for this total reflexion, if we may so call it, of the pressural wave to take place, it is practically not necessary for the ratio of n to m to be zero. If, for example, $n/m = 1/100$, there will be total reflexion if ϕ is greater than 0° 35′, and for so small an angle of incidence as this the component of the vibration normal to the surface on which the pressural wave depends would be too small to produce a measurable effect on the transmitted light.

If we put $\lambda_{,,}/\lambda'' = \mu_0$, then μ_0 is the refractive index of the medium for the normal vibrations, and we have for p

$$p = \frac{\mu_0{}^2 - 1}{\mu_0{}^2 + 1} \quad . \quad . \quad . \quad . \quad . \quad (45)$$

Now, it was shown, first by Haughton,[1] and then by Kurz, that the expressions (39–41) agree with experiment very closely if M or p be treated as a constant to be determined by experiment, and if we suppose p to have the form just given, then for sulphuret of arsenic, for which $\mu = 2{\cdot}454$, according to Jamin, $\mu_0 = 1{\cdot}083$. Green, going further into the mechanism of the motion, has shown, however, that on a strict elastic solid theory we must have $\lambda_{,,}/\lambda'' = \lambda/\lambda'$ and $\mu_0 = \mu$. The last conclusion Eisenlohr calls 'durchaus unhaltbar,' and in this he is right if he means that it does not agree with experiment, but wrong if he means that there is a flaw in Green's theory. The suggestion that μ and μ_0 may be different is due to Haughton,[2] but the reasons he has assigned for it have been shown by Eisenlohr to be invalid. Lord Rayleigh has suggested others which have great weight, and the importance of which will be more clearly seen when we come to consider some recent theories based on the mutual reaction between matter and the ether. The large quantities m and m' are, in Lord Rayleigh's paper, eliminated from the equations by means of the relations

$$m(a'^2 + b^2) \ = \mathrm{D}c^2,$$
$$m'(a_1{}'^2 + b^2) = \mathrm{D}'c^2,$$

D and D′ being the densities of the ether in the two media.

Now, in the pressural wave we are only concerned with a layer of ether close to the bounding surface, and Lord Rayleigh's suggestion is that, although the transverse vibrations are affected nearly in the same way as if the transition were instantaneous, it may not be so for the surface waves, and that therefore we may put $\mathrm{D}/\mathrm{D}' = \mu_0{}^2$ where μ_0 is less than μ. There are, I think, even stronger reasons for supposing μ_0 and μ to be different to be derived from the theory I have already referred to, which will be developed later.

Thus the papers of Lord Rayleigh, Lorenz, and Eisenlohr show, conclusively, that Neumann and MacCullagh's theory is inadmissible, and that Green's strict elastic solid theory, when slightly modified in a per-

[1] Haughton, *Phil. Mag.* (S. 4), vol. vi. p. 81; Kurz, *Pogg. Ann.* t. cviii.
[2] Haughton, *Phil. Mag.* (S. 4), vol. vi. p. 81; Eisenlohr, *Pogg. Ann.* t. civ p. 346.

fectly reasonable way, leads to results agreeing very closely with experiment, while Cauchy's method of treating the pressural wave requires an unstable condition in the ether.

In another paper Lord Rayleigh[1] considers the problem of reflexion at the confines of a medium of variable density. The incidence is supposed to be normal, and in, the particular problem solved completely, the density is supposed to vary as the inverse square of the distance from a fixed plane parallel to the surface. This variable medium extends between the two planes $x=x_1$, $x=x_2$, and the density is constant on the other sides of these planes, and it is shown that if the thickness of the variable layer is not very different from the difference in the wave lengths in the two, then, for the case in which the two media are air and glass, the reflexion will be excessively small.

§ 5. The paper by Kirchhoff[2] in which the problem of reflexion and refraction is considered has been already referred to. The theory there given is, in its results, nearly the same as those of Neumann and MacCullagh.

The ether is not treated strictly as incompressible, though it is supposed that only transverse waves are propagated, and therefore that the equation

$$\frac{du}{dx}+\frac{dv}{dy}+\frac{dw}{dz}=0$$

is satisfied without the coefficient A becoming very large. These transverse waves falling on the interface of the two media would tend to set up longitudinal vibrations. Some surface action, however, is supposed to go on over the interface, the result of which is to quench these vibrations and the condition that this surface action should involve neither loss nor gain if energy is formed. This, with the three equations implied in the continuity of the displacement, makes four conditions from which the intensities and planes of polarisation of the reflected and refracted waves can be found.

The theory differs from MacCullagh's merely in recognising the possibility of the existence of the normal waves, and then accounting for their absence by means of some unknown surface action. It is not a strict elastic solid theory, nor does it attempt to explain of what nature the surface forces are which quench the normal waves. The formulæ to which it leads are identical with MacCullagh's,[3] and do not offer any explanation of the change of phase observed by Jamin. It can hardly be looked upon, therefore, as a satisfactory explanation of the phenomena, nor can we regard Kirchhoff's principle, as the fundamental hypothesis is called by various German[4] writers, as one which may replace the true surface conditions of an elastic solid.

Chapter V.—Metallic Reflexion.

§ 1. Various experimenters—and among them Brewster, MacCullagh, Briot, Airy, Neumann, De Senarmont, Jamin, Quincke, Wernicke, and Conroy—have investigated the optical effects produced by metallic re-

[1] Lord Rayleigh, *Proceedings of London Math. Soc.* vol. xi. No. 159.

[4] See Ketteler, Voigt, etc.

flexions. They have shown that, in general, plane polarised light becomes elliptically polarised by such reflexion, and have measured the difference in phase between the components polarised in and perpendicular to the plane of incidence and the ratio of the intensities of these two vibrations.

MacCullagh [1] was the first to attempt to express the laws of this elliptic polarisation mathematically. He supposes that in the case in question the angle of refraction becomes imaginary, so that we have

$$\sin\phi' = \frac{\sin\phi}{m}\left(\cos\chi + i\sin\chi\right),$$

$$\cos\phi' = \frac{\cos\phi}{m'}\left(\cos\chi' + i\sin\chi'\right).$$

He then substitutes these expressions in the values given by Fresnel's theory for the amplitude of the reflected ray, which he shews may be written in the form $a+b\sqrt{-1}$.

Thus the intensity of this ray will be represented by a^2+b^2, and the difference of phase between the incident and reflected rays will depend on $\tan^{-1}b/a$; a and b are functions of m, m', χ, and χ', and these quantities are connected by the equation $\sin^2\phi'+\cos^2\phi'=1$, which leads to two conditions, giving m' and χ' in terms of m and χ.

The final formulæ are:—

(1) Light polarised in the plane of incidence.

$$I^2 = \frac{D^2 + \cos^2\phi - 2D\cos\phi\cos(\chi-\chi')}{D^2 + \cos^2\phi + 2D\cos\phi\cos(\chi-\chi')} \quad . \quad . \quad (46)$$

$$\tan 2\pi\frac{\delta}{\lambda} = \frac{2D\cos\phi\sin(\chi-\chi')}{\cos^2\phi - D^2} \quad . \quad . \quad . \quad (47)$$

(2) Light polarised perpendicular to the plane of incidence.

$$I'^2 = \frac{m^4\cos^2\phi + D^2 - 2Dm^2\cos\phi\cos(\chi+\chi')}{m^4\cos^2\phi + D^2 + 2Dm^2\cos\phi\cos(\chi+\chi')} \quad . \quad (48)$$

$$\tan 2\pi\frac{\delta'}{\lambda} = -\frac{2Dm^2\cos\phi\sin(\chi+\chi')}{m^4\cos^2\phi - D^2} \quad . \quad . \quad (49)$$

Where and

$$\left.\begin{aligned} D^4 &= m^4 + \sin^4\phi - 2m^2\sin^2\phi\cos 2\chi \\ D^2\sin 2(\chi-\chi') &= m^2\sin 2\chi \end{aligned}\right\} \quad . \quad . \quad (50)$$

These formulæ are simplified in the case of metals from the consideration of the fact that the proportion of light reflected at normal incidence is nearly unity. It follows from this that m is very large and χ' very small, so that we may put $\sin\chi'=0$, $\cos\chi'=1$ in the equations, and hence $m'=\cos\phi/\cos\phi'$,

And for Case I.—

$$\left.\begin{aligned} I^2 &= \frac{m^2 + m'^2 - 2mm'\cos\chi}{m^2 + m'^2 + 2mm'\cos\chi} \\ \tan\frac{2\pi\delta}{\lambda} &= \frac{2mm'\sin\chi}{m'^2 - m^2} \end{aligned}\right\} \quad . \quad . \quad . \quad (51)$$

[1] MacCullagh, *Proc. Irish Acad.* vol. i. pp. 2, 159; vol. ii. 375; *Trans. Irish Acad.* l xxviii. Pt. I.

and Case II.—

$$\left.\begin{aligned} I'^2 &= \frac{1 + m^2m'^2 - 2mm' \cos \chi}{1 + m^2m'^2 + 2mm' \cos \chi} \\ \tan 2\pi \frac{\delta'}{\lambda} &= - \frac{2mm' \sin \chi}{m^2m'^2 - 1} \end{aligned}\right\} \quad . \quad . \quad (52)$$

§ 2. Cauchy [1] has also given equations founded on his principle of continuity and the assumption of a peculiar form for the refracted ray which agree closely with those just established. His complete theory was never published by himself, and was first given by Eisenlohr. It has been further developed and criticised in some important points by Lord Rayleigh. Eisenlohr [2] takes for the displacement in a metal at a distance r from a source of light the expression $e^{\frac{2\pi\iota}{\lambda'}(\rho - r)}$, where λ' is a complex quantity connected with λ, the wave length in air, by the equation

$$\lambda = \lambda' \mathrm{R}e^{ia}.$$

Hence, using θ and θ' to denote the angles of incidence and refraction, we have

$$\sin \theta = \mathrm{R}e^{ia} \sin \theta' \quad . \quad . \quad . \quad . \quad (53)$$

The surface conditions of the continuity of the displacement and of the stresses become, as we have seen, identical with Cauchy's conditions of continuity of motion in the case in which the rigidity of the ether is the same in the two media, and the expressions for the intensity and change of phase for light polarised in the plane of incidence are most easily obtained by transforming Fresnel's sine formula, which is strictly true.

To effect the transformation put

$$\left.\begin{aligned} c^2 \cos 2u &= 1 - \frac{\cos 2a \sin^2 \theta}{\mathrm{R}^2} \\ c^2 \sin 2u &= \frac{\sin 2a \sin^2 \theta}{\mathrm{R}^2} \end{aligned}\right\} \quad . \quad . \quad . \quad (53)$$

Then the intensity in the reflected wave is

$$\mathrm{I}^2 = \tan \left(f - \tfrac{1}{4}\pi\right) \quad . \quad . \quad . \quad . \quad (54)$$

where

$$\cot f = \cos (u + a) \sin 2\tan^{-1}\left(\frac{\cos \theta}{\mathrm{R}c}\right);$$

while d, the change of phase, is given by

$$\tan d = \sin (a + u) \tan 2\tan^{-1}\left(\frac{\cos \theta}{\mathrm{R}c}\right) \quad . \quad . \quad (55)$$

These values agree with those given by MacCullagh if we put

$$\mathrm{R} = m, \quad a = - \chi,$$

[1] Cauchy, *C. R.* t. ii. p. 427; t. viii. pp. 553, 658; t. ix. p. 727; t. xxvi. p. 86. *Liouville's Journal*, t. vii. p. 338.

[2] Eisenlohr, *Pogg. Ann.* t. civ. p. 368.

and therefore
$$\left.\begin{array}{c} c \sec\theta = m', \quad u = \chi' \\ c\mathrm{R} = \mathrm{D} \end{array}\right\} \quad . \quad . \quad . \quad . \qquad (56)$$

For light polarised at right angles to the plane of incidence, Eisenlohr proceeds by transforming Fresnel's tangent formula in a similar manner, and finds
$$\mathrm{I}'^2 = \tan\left(g - \tfrac{1}{4}\pi\right) \quad . \quad . \quad . \quad . \quad . \qquad (57)$$
where
$$\cot g = \cos(a - u) \sin 2\tan^{-1}\left(\frac{c}{\mathrm{R}\cos\theta}\right) . \quad . \qquad (58)$$
and the change of phase is given by
$$\tan d' = \sin(a - u) \tan 2\tan^{-1}\frac{c}{\mathrm{R}\cos\theta} \quad . \quad . \qquad (59)$$

Hence in the general case the ratio of the amplitudes of the two reflected components is $\tan\beta$ where
$$\cos 2\beta = \cos(a + u) \sin 2\tan^{-1}\left(\frac{\sin^2\theta}{c\mathrm{R}\cos\theta}\right) \quad . \quad . \qquad (60)$$
and the difference of phase is given by
$$\tan(d' - d) = \sin(a + u) \tan 2\tan^{-1}\left(\frac{\sin^2\theta}{c\mathrm{R}\cos\theta}\right) \quad . \quad . \qquad (61)$$

These last equations depend on Fresnel's tangent formula, and this we know is not strictly true for transparent bodies. It is hardly probable, therefore, that the final equations for the difference of phase and the ratio of the amplitudes can be accepted as representing accurately the phenomena, and, in fact, Cauchy's theory as here developed is no great advance on MacCullagh's original expressions, with which it agrees throughout.

In this theory the expression for the disturbance in the metal is $e^{\frac{2\pi i}{\lambda}(\rho - r)\mathrm{R}(\cos a + \iota \sin a)}$, or, as we may write it,
$$\mathrm{A}e^{-\frac{2\pi}{\lambda} r\mathrm{R}\sin a} \sin \frac{2\pi}{\lambda}\left(r\mathrm{R}\cos a - ct\right).$$

Hence the velocity of wave propagation is $c/\mathrm{R}\cos a$, as against c in air, and $\mathrm{R}\cos a$ may be called the refractive index of the metal, while $\mathrm{R}\sin a$ measures the co-efficient of absorption. Now Jamin, Quincke, and others have measured the quantities $d - d'$ and β of the formulæ above, and from these Eisenlohr, in the paper already quoted, has calculated the values of R and a. He finds that for silver $a = 83°$. This result Lord Rayleigh has made the basis of a serious criticism on the whole theory.

Lord Rayleigh [1] endeavours to attach a physical meaning to the constants in these formulæ, and in so doing starts from equations taken to represent the motion in the medium.

Thus, for light polarised in the plane of incidence he assumes
$$\mathrm{D}_1 \frac{d^2\zeta}{dt^2} + h\frac{d\zeta}{dt} = n\left(\frac{d^2\zeta}{dx^2} + \frac{d^2\zeta}{dy^2}\right) . \quad . \quad . \qquad (62)$$

[1] Hon. J. W. Strutt, 'On the Reflexion and Refraction of Light by intensely Opaque Matter,' *Phil. Mag.* May, 1872.

with the solutions for the two media,

$$\left.\begin{aligned}\zeta &= \zeta' e^{\,i(ax+by+vt)} + \zeta'' e^{\,i(-ax+by+vt)}\\ \zeta_{\prime} &= \zeta_{\prime} e^{\,i(a_1x+by+vt)}\end{aligned}\right\} \quad . \quad . \quad . \qquad (63)$$

where

$$a = \frac{2\pi}{\lambda}\cos\theta, \qquad b = \frac{2\pi}{\lambda}\sin\theta, \qquad v = \frac{2\pi V}{\lambda},$$

θ being the angle of incidence. If we put $\gamma^2 = n/D$, $\gamma^2{}_1 = n/D_1$, we get from the differential equations—

$$\frac{a_1{}^2 + b^2}{a^2 + b^2} = \frac{\gamma^2}{\gamma_1{}^2}\left(1 - i\,\frac{h}{D_1 v}\right) = \mu^2, \text{ say} \quad . \quad . \quad . \qquad (64)$$

From this we get $\sin\theta' = \dfrac{1}{\mu}\sin\theta$, and hence μ is the quantity which we have denoted by $Re^{i\alpha}$.

Hence
$$R^2 e^{2i\alpha} = \frac{\gamma^2}{\gamma_1{}^2}\left(1 - i\frac{h}{D_1 v}\right). \quad . \quad . \quad . \qquad (65)$$

Thus $R^2 \cos 2\alpha$ is positive, and $R^2 \sin 2\alpha$ is negative, so that 2α lies between 0 and $-\frac{1}{2}\pi$ and $\tan 2\alpha = h/D_1 v$. Again, in the expression for the refracted wave we have $a_1 = \mu a$ when θ is zero, and hence we find that the real part of μ is positive, the imaginary part negative, so that finally α lies between 0 and $-\frac{1}{4}\pi$. This result is contradicted by Eisenlohr's value for silver, in accordance with which $\alpha = 83°$, from which it follows that the real part of μ^2 is negative, and this Lord Rayleigh says is tantamount to assuming the medium to be unstable. Eisenlohr [1] has replied to this that the objection is really one to the form of equation assumed by Lord Rayleigh, and that according to other theories (*e.g.* Helmholtz on anomalous dispersion [2]) real negative values of μ^2 are contemplated. With this reply we may in a sense agree. Lord Rayleigh's objection is a valid one, however, against the supposition that the peculiar effects of metallic reflexion may be explained by the introduction of terms such as $\dfrac{d^{2n+1}\zeta}{dt^{2n+1}}$ in the differential equations of an elastic solid ether, and forms an insuperable argument against the attempt to account for the effects on a purely elastic solid theory. When, however, we come to consider the theories depending on the mutual reaction of the ether and matter, we shall see that under certain circumstances the relation between the periods of the ether and matter molecules may be such as to give a negative value to μ^2, and thus render possible Eisenlohr's value for α.

The general value for a_1 for any angle of incidence may be shown to be given by

$$a_1 = \frac{2\pi}{\lambda} Rc\left\{\cos(u+\alpha) + \iota\sin(u+\alpha)\right\} \quad . \quad . \qquad (66)$$

[1] Eisenlohr, 'On the Reflexion of Light from Metals,' *Wied. Ann.* t. i.

[2] See p. 220.

c and u being defined by the equations of page 195, so that the expression for the refracted wave is

$$\zeta_{\prime} e^{-\frac{2\pi x}{\lambda} \mathrm{R}c \sin(u+a)} \sin \frac{2\pi}{\lambda}\left\{ \mathrm{R}cx \cos(u+a) + y \sin\theta + \mathrm{V}t \right\},$$

where, it must be remembered, x is measured in the negative direction.

Thus the coefficient of absorption is

$$\frac{2\pi}{\lambda} \mathrm{R}c \sin(u+a).$$

According to the experiments of Jamin and Quincke, the refractive index $\mathrm{R}\cos a$ for metal varies between $\frac{1}{4}$ and $\frac{1}{5}$.

§ 3. Wernicke,[1] however, deduced, from some experiments of his own, values lying between 3 and 4. Wernicke's experiments, however, were made by measuring the light transmitted at various angles of incidence by thin films of metal, and assuming that the light absorbed by a thickness d may be expressed by $bk^{d\sec\theta'}$, while the refractive index μ is given by $\sin\theta/\sin\theta'$. Eisenlohr, in the paper already quoted, shows that the quantity calculated by Wernicke is really $\{\mathrm{R}^2+\sin^2\theta\}^{\frac{1}{2}}$, and that his experiments confirm Jamin's and Quincke's.

In the second paper quoted Wernicke suggests, as the complete equations of motion, the form

$$\frac{d^2\xi}{dt^2}+\Sigma h\frac{d^m\xi}{dt^m}=\left(\mathrm{A}-\mathrm{B}\right)\frac{d\delta}{dx}+\mathrm{B}\nabla^2\xi+\Sigma k\frac{d^\mu}{dt^\mu}\left(\nabla^2\xi\right) \quad . \quad . \quad (67)$$

and other equations might be suggested which would give for the disturbance in the metal due to a point source expressions of the form

$$\mathrm{A}\epsilon^{-kr}\sin\frac{2\pi}{\lambda}\left(br-vt\right).$$

Chapter VI.—Diffraction and the Scattering of Light by Small Particles.

§ 1. The principle first enunciated by Huygens, and applied so triumphantly by Fresnel to the phenomena of diffraction, which consists in breaking up a wave front into elementary portions, calculating the effect of each in disturbing a distant point, and then finding the total disturbance at that point by simply summing the effects due to each element of the wave front, is a direct consequence of the fact that the disturbances and velocities are so small that their squares and higher powers may be neglected. The differential equations found for the motion are linear, and the complete solution is the simple sum of all the individual solutions. Again, it is fairly clear that the disturbance produced at any point by an element of a wave front will vary as the area of the element and the reciprocal of the distance between it and the point answered; but it is not so clear how the effect is related to the angles which the line joining the element and the point make with the wave normal and the direction of vibration respectively.

In Fresnel's theory of diffraction the consideration of effects produced

[1] Wernicke, 'On the Reflexion of Light from Metals,' *Pogg. Ann.* t. clix. and clx.

by the variation of these angles is omitted, and that, too, with perfect justice, for he is only concerned with the effects in the neighbourhood of the normal to the primary wave, and the dimensions of the diffracting aperture are small compared with the distance between it and the point at which the effects are considered, so that the change in either of these angles over the whole area of the diffracting area is small.

Again, it is clear that the effect will be a circular function of $r-vt$, r being the distance between the element and the point at which the disturbance is sought, and v the velocity of propagation; but the simple theory does not indicate the relation between the phase of this circular function and that of the function representing the disturbance in the original wave.

§ 2. Both these questions received their complete and final answer in the year 1849 from Professor Stokes.[1] We will quote a few words from the introduction to his paper: 'The object of the first part of the following paper is to determine on purely dynamical principles the law of disturbance in a secondary wave, and that not merely in the neighbourhood of the normal to the primary wave, but in all directions. The occurrence of the reciprocal of the radius in the coefficient, the acceleration of a quarter of an undulation in the phase, and the absolute value of the coefficient in the neighbourhood of the normal will thus appear as particular results of the general problem.'

The equations assumed for the motion are those of an elastic solid in the form given by Green—

$$\left.\begin{aligned} \frac{d^2\xi}{dt^2} &= b^2\nabla^2\xi + \left(a^2 - b^2\right)\frac{d\delta}{dx} \\ \text{etc., where} \qquad \delta &= \frac{d\xi}{dx} + \frac{d\eta}{dy} + \frac{d\zeta}{dz} \end{aligned}\right\} \quad . \quad . \quad . \quad (68)$$

In the preliminary analysis the important general theorem involved in the equations

$$\iint \frac{dV}{dn}ds = \iiint \left(\frac{d^2V}{dx^2} + \frac{d^2V}{dy^2} + \frac{d^2V}{dz^2}\right)dxdydz = 4\pi M \quad . \quad . \quad . \quad (69)$$

is proved.

It is then shown that the solution may be written

$$\xi = \xi_1 + \xi_2 \quad . \quad . \quad . \quad . \quad . \quad (70)$$

where

$$\left.\begin{aligned} \frac{d\xi_1}{dy} - \frac{d\eta_1}{dx} &= 0, \text{etc.,} \\ \frac{d\xi_1}{dx} + \frac{d\eta_1}{dy} + \frac{d\zeta_1}{dz} &= \delta \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad (71)$$

and

$$\left.\begin{aligned} \frac{d\xi_2}{dy} - \frac{d\eta_2}{dx} &= \omega''' \\ \frac{d\xi_2}{dx} + \frac{d\eta_2}{dy} + \frac{d\zeta_2}{dz} &= 0 \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (72)$$

[1] Stokes, 'On the Dynamical Theory of Diffraction,' *Trans. Camb. Phil. Soc.* vol. ix. p. 1; *Math. and Phys. Papers*, vol. ii. p. 243.

and that hence

$$\xi = -\frac{1}{4\pi}\iiint \frac{\delta}{r^2} \cos (rx) dv + \frac{1}{4\pi}\iiint \frac{1}{r^3}(y\omega''' - z\omega'') dv \quad . \quad (73)$$

It is proved that δ and ω', ω'', ω''' satisfy the equation

$$\left.\begin{aligned} \frac{d^2\delta}{dt^2} &= a^2 \nabla^2 \delta \\ \frac{d^2\omega}{dt^2} &= b^2 \nabla^2 \omega \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad (74)$$

and hence, by Poisson's solution,

$$\delta = \frac{t}{4\pi}\iint \mathrm{F}(at)d\sigma + \frac{1}{4\pi}\frac{d}{dt}\left\{t\iint f(at)d\sigma\right\} \quad . \quad . \quad (75)$$

where f and F are the initial values of δ and $d\delta/dt$ respectively.

If, then, the values of δ and $d\delta/dt$, ω and $d\omega/dt$ be given initially everywhere, the last equation, with the similar one for ω, enable us to find δ and ω at any moment throughout the space considered, and then the equation (73) give us ξ, η, and ζ.

In solving the equations for δ, ω, it is clear that if we first find the part of the solution due to the initial velocity, the part due to the initial displacement may be obtained by substituting in the solution for the initial velocity the initial displacement, and then differentiating with regard to the time; and this proposition is proved generally for a system in which the forces depend only on the configuration of the system, and which is executing small vibrations about an equilibrium position.

The integrals are then modified by suitable transformations.

For ξ_1 we have $\xi_1 = \dfrac{d\psi}{dx}$, where $\psi = -\dfrac{1}{4\pi}\displaystyle\iiint \frac{\delta}{r}\, dv.$

Thus $-4\pi\psi$ is the potential of matter distributed throughout space with density δ, and finally it is shown that

$$\psi = -\frac{t}{4\pi}\iiint (u_0 x + v_0 y + w_0 z)\frac{dv}{r^3}(rat) \quad . \quad . \quad (76)$$

where u_0, v_0, w_0 are the initial values of the velocities at the point x', y', z', at which dv is an element of volume, r the distance between x', y', z' and x, y, z, the point at which ψ is to be found. From this ξ_1 can be found, and in a similar manner ξ_2. The terms ξ_1, η_1, ζ_1 arise from a wave of dilatation which is in general set up by any arbitrary displacement, and which travels through the medium with velocity a. If the initial disturbance be such that $\delta_0 = d\delta_0/dt = 0$ everywhere, then this wave will not be formed.

The terms ξ_2, η_2, ζ_2 arise from a wave of distortion which traverses the medium with velocity b. If a disturbance be produced at a point O, and last there for a time τ, then the motion at a point P, at a distance r from O, will not commence until after an interval t, where $t = r/a$, P will be disturbed by a wave of dilatation lasting for an interval τ; it will be disturbed by the wave of distortion after a time r/b, and this disturbance will last for an interval τ.

The general integral is then applied to two cases, which must be carefully distinguished from each other. In the first case, suppose that a periodic force acting parallel to a fixed direction acts throughout a given element of volume in the medium. Let the plane of xz contain the fixed direction, and let the axis of x make an angle α with it. Let D be the density, and T the volume of the element, and let $(\mathrm{DT})^{-1}f(t)dt$ be the velocity communicated to it in time dt.

Then

$$\left.\begin{aligned}
\xi &= \frac{\cos\alpha}{4\pi\mathrm{D}a^2r}f\left(t-\frac{r}{a}\right)+\frac{\cos\alpha}{2\pi\mathrm{D}r^3}\int_{\frac{r}{a}}^{\frac{r}{b}}t'f(t-t')dt \\
\eta &= 0 \\
\zeta &= \frac{\sin\alpha}{4\pi\mathrm{D}b^2r}f\left(t-\frac{r}{a}\right)-\frac{\sin\alpha}{2\pi\mathrm{D}r^3}\int_{\frac{r}{a}}^{\frac{r}{b}}t'f(t-t')dt
\end{aligned}\right\} \quad . \quad . \quad (77)$$

Now, we have seen that in the ether the ratio a/b is probably very large, hence the first term in ξ, on which the normal vibrations depend, is probably very small compared with the first term in ζ. The molecules of an incandescent body may be looked upon, at least very approximately, as centres of disturbing forces, and the above equations show us how it is that from such centres transverse vibrations only are propagated.

If the ether be absolutely incompressible, so that a/b is infinite, then longitudinal vibration would be impossible.

Suppose, now, the first term in ξ omitted, and put $f(t) = c \sin 2\pi bt/\lambda$, Then for the most important term we have—

$$\zeta = \frac{c\sin\alpha}{4\pi\mathrm{D}b^2r}\sin\frac{2\pi}{\lambda}\left(bt-r\right) \quad . \quad . \quad . \quad (78)$$

and the first term in ξ is of the order $\lambda/\pi r$ compared with the leading term in ζ. Hence, except at distances from the source which are comparable with the wave length, the terms in ξ may be neglected, and the motion is strictly transverse.

This solution applies to the case of an element of volume vibrating in any given manner and emitting light into the surrounding space. Everything is symmetrical around the direction of vibration of the element of volume. It does not apply, as has been supposed by some writers, to the problem of diffraction; for in this case we have a train of waves being propagated through an aperture, and producing disturbance in the medium beyond.

Let us suppose the aperture to be plane, and that plane waves are being propagated through it in the direction of its normal; take this for the axis of x, the plane of the aperture being $x = 0$, and the axis of z the direction of vibration. Let O_1 be a point in the aperture, and consider the disturbance propagated in a small interval of time τ, across an element $d\mathrm{S}$, at O_1. This disturbance occupies a film of thickness $b\tau$, and consists of a displacement $f(bt')$ and a velocity $bf'(bt')$. Thus, for a point O, at a distance r from O_1, and at a time t, given by $t = t' + r/b$, the initial disturbance is the above displacement and velocity extending over a volume $b\tau d\mathrm{S}$ about O; and if l, m, n are the direction

cosines of O_1O, measured from O_1, then the values of ξ, η, ζ depending on the initial velocity are—

$$\left.\begin{aligned} \xi' &= -\frac{lnds}{4\pi r} f'\left(bt-r\right) \\ \eta' &= -\frac{mnds}{4\pi r} f'\left(bt-r\right) \\ \zeta' &= \frac{(1-n^2)ds}{4\pi r} f'\left(bt-r\right) \end{aligned}\right\} \quad . \quad . \quad . \quad (79)$$

while the values depending on the initial displacement are—

$$\left.\begin{aligned} \xi'' &= -\frac{l^2nds}{4\pi r} f'\left(bt-r\right) \\ \eta'' &= -\frac{lmnds}{4\pi r} f'\left(bt-r\right) \\ \zeta'' &= \frac{l(1-n^2)ds}{4\pi r} f'\left(bt-r\right) \end{aligned}\right\} \quad . \quad . \quad . \quad (80)$$

From this it follows that the vibration at O, arising from that at O_1, lies in the plane through O_1O and the axis of z, and is perpendicular to the radius O_1O; and if ϕ be the angle between the axis of z and the line O_1O, θ that between O_1O and the wave normal, the value of this displacement is—

$$\zeta = \frac{dS}{4\pi r}\left(1 + \cos\theta\right) \sin\phi f'\left(bt-r\right) \quad . \quad . \quad (81)$$

Hence if $$f(bt) = c \sin\frac{2\pi}{\lambda} bt,$$

$$\zeta = \frac{cdS}{2\lambda r}\left(1 + \cos\theta\right) \sin\phi \cos\frac{2\pi}{\lambda}\left(bt-r\right) \quad . \quad . \quad (82)$$

and the total effect at O will be found by integrating this over the whole wave front.

We have thus found the complete expression for the law of disturbance in the secondary wave, and can see in what way it involves θ and ϕ, and how its phase is related to that of the disturbance over the primary wave.

The theory of diffraction given by Fresnel, and applied by him to points in the neighbourhood of the principal wave normal, is thus fully justified, since for such points θ is small, and $\cos\theta$ therefore approximately unity, while ϕ is nearly constant. The expression shows that an addition of a quarter period must be made to the phase; but this will not affect the form of the diffraction pattern obtained.

But the results of the investigation are of even more importance in their bearing on the relation between the position of the plane of polarisation and the direction of vibration of plane polarised light. For consider a ray diffracted in a direction making an angle θ with the incident wave normal, and let the plane containing the incident and diffracted ray be called the plane of diffraction, and let the directions of vibration

in the incident and diffracted rays make angles α_i, α_d with the normal to the plane of diffraction. Then the diffracted ray and the two directions of vibrations lie in the same plane, and the directions of vibrations are normal to the respective rays. Thus, if we form a spherical triangle by drawing lines from the centre of a sphere, parallel to the normal to the plane of diffraction and to the two directions of vibrations, since the direction of vibration in the diffracted wave is the projection on that wave of the direction of vibration in the incident wave, we have

$$\cos\theta = \tan\alpha_d \cot\alpha_i \quad . \quad . \quad . \quad . \quad (83)$$

Now, let ϖ and α be the azimuths of the planes of polarisation of the incident and diffracted light, measured from a plane normal to the plane of diffraction. Then, on Fresnel's assumption that the direction of vibration is normal to the plane of polarisation, we have

$$\varpi = \frac{\pi}{2} + \alpha_i, \qquad \alpha = \frac{\pi}{2} + \alpha_d,$$

and

$$\tan\alpha = \sec\theta \tan\varpi;$$

while on MacCullagh's hypothesis

$$\varpi = \alpha_i, \qquad \alpha = \alpha_d,$$

and

$$\tan\alpha = \cos\theta \tan\varpi \quad . \quad . \quad . \quad . \quad (84)$$

These two formulæ can be tested by experiment, and afford a means, therefore, of deciding between the two theories of reflexion, and of determining the question whether reflexion be due to a change of density or to a change of rigidity in the ether; for the values of α corresponding to a series of values of ϖ can be observed for any given angle of diffraction, and if the values of ϖ be taken at equidistant intervals, the values of α, and therefore the positions of the plane of polarisation of the diffracted light, will not be equidistant, but will on the first hypothesis be crowded towards the plane of diffraction, while on the second they will be crowded away from that plane.

Professor Stokes was the first to carry out a series of observations of this nature; he employed a grating ruled on glass at the rate of 1,300 lines to the inch, and the results of his experiments are decisive in favour of Fresnel's hypothesis. The experiments are troublesome, and the comparison of the results with theory is complicated by the fact that the refraction through the glass plate on which the grating is ruled also produces a change in the position of the plane of polarisation. The amount of this change is the same on the two theories, and tends to produce a crowding of the planes of polarisation away from the plane of diffraction, an effect opposite to that produced by diffraction on Fresnel's theory. Moreover, we may suppose that, when the ruled face of the grating is towards the incident light, either the diffraction takes place in air so that the wave enters the glass obliquely, or that the diffraction takes place in the glass after the light has entered the first surface normally, while when the ruled surface is away from the incident light the diffraction may take place in air after passing normally through the glass, or in the glass so that the light after passing normally through the first surface emerges obliquely.

In any case we shall have

$$\tan \alpha = m \tan \varpi \quad . \quad . \quad . \quad . \quad . \quad (85)$$

where m is a function of the angle of diffraction and the refractive index, which can be calculated on either of the above hypotheses.

The results were reduced by plotting from the experiments a curve with $\log m$ as ordinates and θ, the angle of diffraction, as abscissæ. The curves given by the two theories on either of the above assumptions as to the relation between diffraction and refraction were also drawn, and a comparison of the two results 'leaves no reasonable doubt that the experiments are decisive in favour of Fresnel's hypothesis, if the theory be considered as well founded.' And, moreover, the comparison shows us that we must suppose the diffraction to take place before the refraction. Thus, when the grooved face is towards the incident light we must suppose the wave to be broken up in the air and then to be obliquely refracted through the glass, while when the grooved face is away from the light the wave must be treated as if it were diffracted in the glass and then obliquely refracted out, and Professor Stokes shows that it is *à priori* more probable from physical reasons that this is what takes place.

§ 3. In the results of the experiments a certain amount of irregularity is produced by the want of symmetry of the grooves of the grating, and Holtzmann,[1] who in 1856 repeated Stokes's experiments, failed to obtain consistent results with glass gratings, and had recourse in consequence to a Schwerd's lamp-black grating; with this he obtained results more in accordance with the theory of Neumann and MacCullagh than with that of Fresnel.

Holtzmann thought that Stokes had neglected to consider the effect of the longitudinal waves, 'and to this neglect he attributes the error of Mr. Stokes;' and Eisenlohr,[2] who 'had not read the great paper of Prof. Stokes,' attributes to him the same neglect, and endeavours to give a theoretical account of the question from Cauchy's standpoint. Of course both these authors were quite wrong in their estimate of Stokes's work, and Lorenz[3] showed, from some decisive experiments of his own, that Holtzmann's results were due to an error of his method. Lorenz gave a fresh demonstration of Stokes's theorem, and arrived at the same results. Lorenz appears to consider his method as more general than that of Stokes, but this is due to a misconception on his part. The results of his experiments agree with Fresnel's theory.

§ 4. The matter has since been experimentally investigated by Quincke,[4] who showed that the method of forming the grooves on the grating was of the utmost importance, and whose experiments led to no decisive results, and more recently by Fröhlich.[5] Fröhlich investigated the polarisation of the light reflected from a glass grating, but did not compare his results with theory. A few experiments of the same kind were made by Stokes in 1852, but he also omitted the comparison with theory.

[1] Holtzmann, *Pogg. Ann.* t. xcix. p. 446.

[3] L. Lorenz, *Pogg. Ann.* t. cxi. p. 315.
[4] Quincke, 'Experimentelle optische Untersuchungen,' *Pogg. Ann.* t. cxlix. p. 73.
[5] Fröhlich, *Wiedemann*, t. i.

Réthy [1] developed a theory which covers Fröhlich's experiments, and arrived at a formula with which they agree closely, but his fundamental principles are at fault.

In his solution Réthy adopts a method given by Kirchhoff to find the effects of a given source of light.

The equations to be solved are, if we neglect the terms involving dilatation,

$$\frac{d^2u}{dt^2}=\mathrm{V}^2\nabla^2u,$$

etc., with the condition

$$\frac{du}{dx}+\frac{dv}{dy}+\frac{dw}{dz}=0.$$

Take

$$\Phi=\frac{\mathrm{A}}{r}\sin 2\pi\left\{\frac{r}{\lambda}-\frac{t}{\mathrm{T}}+\epsilon\right\} \quad . \quad . \quad . \quad (86)$$

Then Φ and its differential coefficients satisfy the equations of motion, and we require to find such solutions as will satisfy the equation of continuity.

Réthy takes as solutions—

I. $$u=\frac{d\Phi}{dy},\ v=-\frac{d\Phi}{dx},\ w=0 \quad . \quad . \quad . \quad . \quad (87)$$

and

II. $$u=-\frac{d^2\Phi}{dxdy},\ v=-\frac{d^2\Phi}{dydz},\ w=\frac{d^2\Phi}{dx^2}+\frac{d^2\Phi}{dy^2} \quad . \quad . \quad (88)$$

The distance r, of course, is measured from a point on the grating to the point at which the motion is being considered.

Now each of these expressions of course represents the solution due to some arbitrary motion set up somehow over the grating. In Case I. the motion is a periodic twist of each element about the axis of z, while in Case II. it is an oscillation parallel to that axis. But Réthy does not show how this motion is to be set up, nor whether it can represent the effect of a train of plane waves falling on the grating and there diffracted; and a little consideration shows that it cannot, for, according to the ordinary assumed properties of the ether, we cannot get the wave of twist only without linear displacement; the second solution corresponds to that due to the action of a periodic force at the origin generating a certain amount of momentum, and not to the complete effect of a train of waves. If we compare it with Stokes's solution, we see that it is that part which arises from the effects of the velocity propagated across the element, and omits the part due to the displacement. Stokes's solution applies to the case in which energy is being propagated by waves passing across the orifice into the medium beyond, and depends on the direction of motion of these main waves. Réthy's solution is that which arises from a centre of vibration situated on the surface, kept in motion by some external force and sending out waves in all directions into the medium. Still, we can arrive at a formula of the same nature as that given by Réthy, and which does agree with Fröhlich's experiments, by means of a simple extension of Stokes's principles. This consists in supposing that

[1] Réthy, *Wied. Ann.* t. xi. p. 504.

the incident waves set up vibrations over the surface parallel to a fixed direction, and that these vibrations lie in the same plane as the incident vibrations, while these vibrations set up others in the diffracted waves which lie in the same plane as those over the surface, and are everywhere normal to the diffracted rays. Then, if e_0 be the angle between the incident wave normal and the disturbance over the surface, ϕ_0 and ϕ the azimuths of the planes of polarisation on Fresnel's hypothesis measured from the plane of incidence in the incident and diffracted waves, and δ the angle of diffraction, it can be shown that[1]

$$\cos\phi_0 \tan\phi = \sin\delta \cot e_0 + \cos\delta \sin\phi_0 \quad . \quad . \quad (89)$$

This expression is given by Réthy, and agrees closely with the results of Fröhlich's experiments which were made with two gratings—the one of 19·76 lines to a millimetre, the other of 162 lines to a millimetre.

The value of e_0 depends on the angle of incidence when this vanishes, so that the vibrations in the incident wave are parallel to the surface $e_0 = 90°$, and the above formula becomes identical with Stokes's.

In comparing the two it must be remembered that the azimuths of the planes of polarisation are measured, in Stokes's expression, from the normal to the plane of incidence, while in Réthy's they are measured from the plane of incidence.

A careful series of experiments by Cornu[2] also lead to the conclusion that the vibrations are normal to the plane of polarisation. This conclusion coincides with that arrived at by Lord Rayleigh and Lorenz from considerations based on the phenomena of reflexion and refraction, and is further strengthened by the phenomena of polarisation produced when light is scattered by a series of small particles.

§ 5. Before considering this, reference must be made to a paper by Professor Rowland,[3] of Baltimore, on the subject. This paper will be more completely discussed when we come to the electro-magnetic theory, to which it more properly belongs. Professor Rowland, however, considers that he has discovered an error in Stokes's work, in that according to it 'when a wave is broken up at an orifice the rotation is left discontinuous by Stokes's solution.' It is not quite clear, however, how this criticism is intended to apply; for the rotation in the main wave is completely determined when the displacement is known. Now, Professor Stokes has shown that when the orifice is of finite size the aggregate disturbance at any point due to all the elements of the orifice, as found by his formula, is the same as if the wave had not been broken up. The rotation, therefore, as given by this formula is also the same.

Again, the rotation is propagated according to the same laws as the transverse disturbance, and hence the elementary rotation due to a given element of a wave propagated in a given direction is related to the direction and to the total rotation of the element in the same way as the elementary displacement propagated in that direction is related to the actual displacement.

Thus, if the displacements over the wave be

$$\xi = 0, \quad \eta = 0, \quad \zeta = c \sin\frac{2\pi}{\lambda}(bt - x),$$

[1] See Glazebrook, *Proc. Camb. Phil. Soc.* vol. v. p. 254. [2] Cornu, *C. R.*
[3] Rowland, 'On Spherical Waves of Light,' *Phil. Mag.* June, 1884.

the rotations are

$$0, \quad \frac{2\pi}{\lambda} c \cos \frac{2\pi}{\lambda}(bt-x), \quad 0;$$

and the elementary rotation to which this gives rise is

$$\omega_2 = -\frac{\pi c}{\lambda^2 r} dS\,(1 + \cos\theta)\sin\psi \sin\frac{2\pi}{\lambda}(bt - r),$$

ψ being the angle between the axis of y and the radius vector r. This elementary rotation takes place about a line perpendicular to the radius vector, and lying in a plane containing it and the axis of y.

On passing from one medium to another the rotation is not necessarily continuous. The only surface conditions are that the displacements and the stresses are the same on the two sides of the surface of separation, and if the rigidity of the ether be different in the two media the rotations will be different also. But Professor Stokes's solution does not apply to this case, and for the case to which it does apply is complete.

Chapter VII.—The Scattering of Light by Small Particles.

§ 1. In his experiments on the light scattered from precipitated clouds of fine matter, Tyndall [1] showed that when the particles are sufficiently fine the light emitted laterally is blue in colour, and in a direction perpendicular to that of the incident beam it is completely polarised.

The full explanation of this was given by Lord Rayleigh in 1871 in a series of papers [2] having an important bearing on our present subject—the relation between the plane of polarisation and the direction of vibration of plane polarised light. Professor Stokes, in his paper on fluorescence,[3] had indicated the connection between the two questions.

For consider a beam travelling horizontally, and look at it vertically downwards: the scattered light is in great part polarised in the plane of reflection. If the scattering particles be small compared with the wave length of the incident light, the vibrations in an incident ray cannot be at right angles to those in a scattered ray. For the incident vibrations are affected by the dust particles, which in consequence of their very great mass relative to the ether remain practically at rest.

We may treat the problem as if the dust particles moved exactly as the ether which they replace would do, and then superpose on this motion an equal and opposite motion. The first motion will not affect the regular propagation of the waves. In consequence of the second the particles become centres of disturbance, and set up other motions in the ether. These other motions will depend on the direction of apparent motion of the dust particles, and the optical effect in any direction will depend on the component of the motion at right angles to that direction. Now, the reflected ray is polarised in the plane of reflexion. If, then, the

[1] Tyndall, *Phil. Mag.* (4), vol. xxxvii.

[2] J. W. Strutt, 'On the Light from the Sky, its Polarisation and Colour,' *Phil. Mag.* Feb. and April, 1871; 'On the Scattering of Light by Small Particles,' June, 1871.

[3] Stokes 'On the Change of Refrangibility of Light,' *Phil. Trans.* 1852.

vibrations be in the plane of polarisation they will be at right angles to those in the incident light, while if the vibrations be at right angles to the plane of polarisation, they will come from the component of the original vibration, which is at right angles to that plane. If, then, on this supposition as to the relation between plane of polarisation and direction of vibration the incident light be polarised at right angles to the plane of reflection—*i.e.*, in the case before us in a horizontal plane—the light scattered in the vertical direction should vanish, and this is found to be the case. This general reasoning is substantiated by Lord Rayleigh in the papers before us by mathematical reasoning, and, moreover, he shows that the intensity of scattered light in any direction varies inversely as the fourth power of the wave length.

This may be seen from a consideration of the dimensions involved.

The ratio of the two amplitudes in the scattered and incident vibration will be a number. It must also involve the volume of the dust particles, being directly proportional to it, and it also will be inversely proportional to r, the distance from the disturbance; it must therefore depend on $T/\lambda^2 r$.

The mathematical expression for the disturbance is found as follows:—Let D' be the density of the ether in the dust particles, D in the space surrounding them. Let the vibrations in the incident wave, when they strike the dust, be given by $A \cos \frac{2\pi}{\lambda} bt$. Then the acceleration is

$$-A\left(\frac{2\pi}{\lambda} b\right)^2 \cos \frac{2\pi}{\lambda} bt.$$

In order that the wave may pass on undisturbed through the parts where the density is D', force would require to be applied; the amount of the force will be

$$-A(D'-D)\left(\frac{2\pi b}{\lambda}\right)^2 \cos \frac{2\pi}{\lambda} bt$$

per unit volume, and hence a force

$$A(D'-D)\left(\frac{2\pi b}{\lambda}\right)^2 \cos \frac{2\pi}{\lambda} bt,$$

conceived to act at O, the position of the particle, gives the same disturbance as is caused by the particle. Now, we have seen in Professor Stokes's paper that a force $F \cos \frac{2\pi}{\lambda} bt$ per unit of volume produces a displacement at any other point given by

$$\zeta = \frac{F \sin \alpha}{4\pi b^2 D r} \cos \frac{2\pi}{\lambda}(bt - r),$$

which is this case comes to

$$\zeta = A \frac{D'-D}{D} \frac{T}{r\lambda^2} \sin \alpha \cos \frac{2\pi}{\lambda}(bt - r) \quad . \quad . \quad . \quad (90)$$

where α is the angle between the radius vector r and the direction of the force F, and the displacement takes place in the plane passing through the directions of the force and the radius vector, and is at right angles to the latter.

Lord Rayleigh's paper concludes with another proof of the formula which gives the motion due to a force acting parallel to the axis of z. Put for the force Ze^{int}, then the equations of motion become, when expressed in terms of the rotation,

$$\left.\begin{aligned}(b^2\nabla^2+n^2)\,\omega_3&=0\\(b^2\nabla^2+n^2)\,\omega_1&=\frac{dZ}{dy}\\(b^2\nabla^2+n^2)\,\omega_2&=-\frac{dZ}{dz}\end{aligned}\right\}\quad . \quad . \quad . \quad . \quad (91)$$

Hence

$$\omega_1=\frac{1}{4\pi b^2}\iiint Z\,\frac{d}{dy}\left(\frac{e^{-ikr}}{r}\right)dxdydz$$

where

$$k=\frac{2\pi}{\lambda}=\frac{n}{b},$$

and the integral extends over the space T, through which the force acts.

Within this space $\frac{d}{dy}\left(\frac{e^{-ikr}}{r}\right)$ is sensibly constant; and if ω be the resultant rotation which will take place about an axis perpendicular to the plane through z and the radius vector,

$$\omega=-\frac{ikTZ\sin\alpha}{4\pi b^2}\,\frac{e^{-ikr}}{r}.$$

Hence

$$\zeta=\int\omega dr=\frac{TF\sin\alpha}{4\pi b^2 r}\cos\frac{2\pi}{\lambda}(bt-r)\quad . \quad . \quad (92)$$

In the second paper mentioned above Lord Rayleigh points out that the cause of reflexion may be diminished rigidity rather than increased density, and that in this case a scattered ray might be composed of vibrations perpendicular to those of the incident ray; he then proceeds to describe experiments on the composition of the light of the sky, made with a view of showing that it is such as would result, according to the above formula, from light scattered by small particles. And in the third paper he discusses the motion in an elastic solid in which the density and rigidity vary from point to point.

The problem is solved for two media differing slightly in density and rigidity, and it is shown that in a direction normal to the incident ray the rotation in the scattered ray, when the incident vibrations are parallel to z, is given by

$$\omega^2=p^2\left(\frac{\Delta n}{n}\right)^2\frac{z^2}{r^2}+p^2\left(\frac{\Delta D}{D}\right)^2\frac{y^2}{r^2}\quad . \quad . \quad . \quad (93)$$

where

$$p=\frac{ik^3T}{4\pi}\frac{e^{-ikr}}{r}$$

Hence, if Δn and ΔD are both finite, the scattered light can never vanish in a plane normal to the incident ray.

Now we know from experiment that it does vanish, and hence either Δn or ΔD must be zero. If we put $\Delta D=0$, it can be shown from the general expression for the rotation that there are six directions along which the scattered ray vanishes, for the components of the rotation are given by—

$$\left.\begin{aligned}\omega_3 &= -p\frac{\Delta n}{r}\frac{yz}{r^2}\\ \omega_1 &= p\frac{\Delta n}{n}\frac{xy}{r^2}\\ \omega_2 &= p\frac{\Delta n}{n}\frac{z^2-x^2}{r^2}\end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad (94)$$

Now, there is nothing in the experimental results which at all leads to such a conclusion. If the hypothesis of a variable density be adopted, and Δn be put zero, then,

$$\left.\begin{aligned}\omega_3 &= 0\\ \omega_1 &= p\frac{\Delta D}{D}\frac{y}{r}\\ \omega_2 &= p\frac{\Delta D}{D}\frac{x}{r}\end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad (95)$$

and the light vanishes in one direction only, viz. that of the axis of z. This result, of course, agrees with that of the former paper, and we must conclude that Fresnel's explanation of the cause of reflexion is the true one, while MacCullagh's is false, and that in plane polarised light the vibrations are perpendicular to, not parallel to, the plane of polarisation. The theory as left in this paper does not explain the phenomenon of the residual blue discovered also by Tyndall, who found that at a certain stage in the growth of the particle causing the scattering some light is discharged by the cloud parallel to the direction of vibration of the incident light, and that this light is of a very intense blue tint.

Lord Rayleigh points out that this may be due to the higher powers of $\Delta D/D$, which have been omitted, and in a more recent paper, based on the electro-magnetic theory, he develops this point more completely.[1]

Chapter VIII.—General Conclusions.

§ 1. Space compels us to conclude with this the general account of recent work on optical theories based solely on the elastic solid theory. Special problems of various kinds have received their solution, but to these we can only allude; indeed, for several of them the general properties of wave motion with the principle of interference are all that are required. Such, for example, are the papers by Prof. Stokes, 'On the Theory of certain Bands seen in the Spectrum,'[2] 'On the Formation of the Central Spot in Newton's Rings beyond the Critical Angle.'[3]—This is shown, as was suggested by Lloyd, to be due to the surface disturbance, which takes the place of the refracted wave when the angle of incidence

exceeds the critical angle.—'On the Perfect Blackness of the Central Spot in Newton's Rings, and on the Verification of Fresnel's Formulæ for the Intensities of the Reflected and Refracted Rays.'[1] In this paper is given the now well-known proof of Arago's law that light is reflected in the same proportion at the first and second surfaces of a transparent plate. 'On the Colours of Thick Plates,'[2] and 'On the Composition and Resolution of Streams of Polarised Light from different sources.'[3]

In his 'Investigations in Optics, with special reference to the Spectroscope,' published in the 'Philosophical Magazine' for 1879 and 1880, Lord Rayleigh has considered the application of the principles of the wave theory to geometrical optics, and the construction of optical instruments. A full account of these is given in the article 'Optics,' in the 'Encyclopædia Britannica.'

Professor Stokes's great paper on Fluorescence[4] is chiefly experimental. The cause of the phenomena is assigned to the vibrations set up by the incident light in the molecules of the fluorescent substance, which themselves react on the ether and emit the fluorescent light. According to Stokes the vibrations in this light are never of shorter period than those in the incident light; and he in a general way endeavours to account for this, and shows that if the force acting on a given matter molecule due to a given displacement be proportional to a positive integral power of the displacement other than the first, then the amplitude of the displacements would involve the period, and there would be a tendency to increase the amplitudes of vibrations of lower period than that of the incident light, and to decrease the amplitudes in the case of vibrations of higher period than that of the incident light. Thus, in a group of disturbed molecules we should expect all possible periods between two, the upper corresponding to the refrangibility of the incident light, the lower corresponding to the natural period of the molecules. This result, known as Stokes's law, has been the cause of much discussion. Some physicists[5] hold that they have found fluorescent substances which constitute an exception to it, while others,[6] who have carefully repeated the critical experiments, draw conclusions in accordance with the law; and the weight of the evidence is with the latter.

A general account of the principles of the elastic solid theory was given in his lectures at Baltimore last year by Sir William Thomson.[7] To these we shall return in the next section.

§ 2. In concluding this part of the report we may say, then, that while the elastic solid theory, taken strictly, fails to represent all the facts of experiment, we have learnt an immense amount by its development, and have been taught where to look for modifications and improvements. We may, I think, infer that the optical differences of bodies depend mainly on differences in the density or effective density of the ether in those bodies, and not on differences of rigidity. Fresnel's general theory of the cause of reflexion is thus seen to be true, and Green's theory of

[7] Thomson, *Lectures on Molecular Dynamics.*

reflexion and refraction can be made to agree with experiment by the simple supposition that for longitudinal and transverse disturbances respectively, the ether in a transparent body is loaded differently. This same theory of the loading of the ether will not account for double refraction if we assume that the vibrations are strictly in the wave front. If, however, we admit that in a crystal the vibrations may be normal to the ray, instead of in the wave front, Fresnel's beautiful laws follow at once from the equations given by Lord Rayleigh, which are quite consistent with the theory of reflexion and refraction, but there is a difficulty in dealing with the pressural wave. Neither of the strict elastic solid theories of Green can be accepted as representing the facts of experiment, and the interesting modification of Green's theory suggested by De St. Venant fails also. In all there are too many constants for the requirements of the experimental results, and the theories do not indicate the meaning of the arbitrary relations between these constants with sufficient clearness and certainty.

The suggestions of Cauchy and Briot, with the elegant mathematics of Sarrau on the periodic distribution of the ether in a transparent body, lead to expressions for the relation between the refractive index and wave length which agree well with experiment so long as we steer clear of substances which present the phenomena of anomalous dispersion, but of this they give no account.

While the formulæ given by Cauchy and Eisenlohr seem to represent the laws of metallic reflexion with considerable exactness, the theory on which these formulæ rest, requiring as it does a negative value for the square of the refractive index, is inconsistent with the conditions of stability of an elastic solid.

Nor is it surprising that a simple elastic solid theory should fail. The properties we have been considering depend on the presence of matter, and we have to deal with two systems of mutually interpenetrating particles. It is clearly a very rough approximation to suppose that the effect of the matter is merely to alter the rigidity or the density of the ether. The motion of the ether will be disturbed by the presence of the matter; motion may even be set up in the matter particles. The forces to which this gives rise may, so far as they affect the ether, enter its equations in such a way as to be equivalent to a change in its density or rigidity, but they may, and probably will, in some cases do more than this. The matter motion will depend in great measure on the ratio which the period of the incident light bears to the free period of the matter particles. If this be nearly unity, most of the energy in the incident vibration will be absorbed in setting the matter into motion, and the solution will be modified accordingly.

PART III.

THEORIES BASED ON THE MUTUAL REACTION BETWEEN THE ETHER AND MATTER.

Chapter I.—THE PROPAGATION OF WAVES THROUGH TWO MUTUALLY INTERPENETRATING MEDIA.

§ 1. In the optical theories hitherto considered attempts have been made to account for the phenomena of reflexion, refraction, and dispersion by the hypotheses of modifications produced in the properties of the ether

by the reaction of the material particles of the medium through which the light was being propagated. According to Fresnel the density of the ether is affected, while according to Neumann and MacCullagh it is to changes in the rigidity that the effects are due.

In both cases the direct effects of the communication of momentum from the ether to the material particles of the transparent medium is not considered. Fresnel,[1] it is true, thought it 'probable' that the molecules of ponderable matter should partake of the movement of the 'ether which surrounds them on all sides,' and Cauchy,[2] in one memoir, deals with the motion of two mutually interpenetrating systems of molecules, but without arriving at any specially important result. Voigt[3] states that about 1865 F. Neumann was in the habit of treating, in his lectures, the system of simultaneous equations relating to the motion of ether and matter. Briot,[4] in his work on dispersion, considers the direct reaction between matter and ether particles, but in his final result equates, as we have seen,[5] the term expressing it to zero.

§ 2. In 1867 a paper was presented to the French Academy by M. Boussinesq[6] on the 'Théorie nouvelle des ondes lumineuses.' In this paper the dynamical effects of momentum communicated by the ether to the molecules of ponderable matter are considered as the cause of reflexion, refraction, polarisation, dispersion, &c.

The ether is treated as homogeneous, and of the same density and rigidity in all bodies, and it is supposed that when light enters a transparent medium the molecules of that medium may be set in vibration isochronously with those of the ether. We have thus to consider the forces acting on such a medium, and these may be divided into three parts: (1) those which arise from the elastic reactions of the ether, (2) those arising from the elastic reactions of the matter, and (3) those arising from the mutual action between matter and ether.

Now let us consider a small element of volume, containing both matter and ether. Let m be the density of the ether, μ of the matter, u, v, w the displacements of the ether in the element, U, V, W those of the matter. Then, using Green's notation, the force, measured parallel to the axis of x, arising from (1) will be per unit of volume—

$$(\mathrm{A}-\mathrm{B})\frac{d\theta}{dx}+\mathrm{B}\nabla^2 u,$$

where
$$\theta=\frac{du}{dx}+\frac{dv}{dy}+\frac{dw}{dz}.$$

For the forces arising under (2) we have to consider that $m\frac{d^2u}{dt^2}$ and $\mu\frac{d^2\mathrm{U}}{dt^2}$ will be quantities of the same order; but μ is very great indeed compared with m, and hence U is very small compared with u. The

[3] *Wied. Ann.* t. xvii. p. 473.
[4] *Essais sur la théorie mathématique de la lumière.* Paris: 1865.
[5] See p. 181.
[6] *C. R.* t. lxv. p. 235; *Liouville's Journal*, s. ii. t. xiii. p. 313. A most clear account of this theory is given by M. de St. Venant in the article already quoted, 'Théorie des ondes lumineuses,' *Ann. de Chim.* s. ix. t. xxv. p. 368 *seq.*

forces (2) depend on U and its differential coefficients, and it is assumed in the theory that in consequence of the excessive smallness of U they may be neglected. Again, let us suppose that the dimensions of the element of volume are large compared with the distance through which the action of an ether particle on a matter particle is appreciable. Then we may consider the mutual reaction between matter and ether as confined entirely to the element of volume considered, the actions taking place across the surfaces of the element will just balance each other, and hence, if we consider the matter and ether as one system, the force (3) will be zero, and the equations of motion will be

$$m\frac{d^2u}{dt^2}+\mu\frac{d^2\mathrm{U}}{dt^2}=(\mathrm{A}-\mathrm{B})\frac{d\theta}{dx}+\mathrm{B}\nabla^2u,\ \text{etc.} \quad . \quad . \quad (1)$$

U is here the displacement of the matter occupying the same element of volume as the ether, whose displacement is u, but all the displacements being very small, it is assumed that we may treat U and u as the displacements of the matter and ether, which when at rest occupy the same element of volume. Thus U, V, W are functions of u, v, w and their differential coefficients with respect to x, y, z, the initial co-ordinates, and may be expanded in terms of these, and it remains to find the form of the expansion.

Conditions are, of course, imposed by the fact that the medium is isotropic, and it is shown that so far as second differential coefficients we may write

$$\mathrm{U}=\mathrm{A}u+\mathrm{C}\frac{d\theta}{dx}+\mathrm{D}\nabla^2u,\ \text{etc.} \quad . \quad . \quad . \quad (2)$$

On substituting this value of U, in the equation of motion, and assuming $u=\mathrm{M}e^{i\frac{2\pi}{\tau}\left(t-\frac{mx+ny+pz}{w}\right)}$ etc., we obtain

$$(\rho+\rho_1\mathrm{A})\frac{d^2u}{dt^2}=\left(\lambda+\mu+\frac{4\mathrm{C}\pi^2\rho_1}{\tau^2}\right)\frac{d\theta}{dx}+\left(\mu+\frac{4\mathrm{D}\pi^2\rho_1}{\tau^2}\right)\nabla^2u \quad . \quad (3)$$

And these equations, of course, give a normal wave travelling with a velocity $[\{\lambda+2\mu+4(\mathrm{C}+\mathrm{D})\pi^2\rho_1/\tau^2\}/(\rho+\mathrm{A}\rho_1)]^{\frac{1}{2}}$, and a transverse wave with velocity $[\{\mu+4\mathrm{D}\pi^2\rho_1/\tau^2\}/(\rho+\mathrm{A}\rho_1)]^{\frac{1}{2}}$.

These velocities vary with the period of vibration in a manner which agrees, at least approximately, with experiment. It is clear that the coefficient A is positive, while the experimental fact that the velocity increases with the period shows that D is negative. The condition that A is positive merely implies that the ether tends to move the matter particles in the same direction as it moves in itself.

If we suppose that the medium is not isotropically symmetrical, while at the same time it is such that the expressions retain the same form when two of the axes are turned through a small angle about the third, then terms $\mathrm{B}\left(\frac{dv}{dz}-\frac{dw}{dy}\right)$ come into the value for U, and these, it is shown, would cause the medium to produce rotation of the plane of polarisation of a plane polarised ray traversing it. This rotation would vary approximately inversely as the square of the period, in accordance with the law discovered by Briot. By introducing higher differential coefficients into

the value of U in terms of u, etc., it is shown that these approximate laws become, respectively,

$$V^2 = V_0^2\left(1 + \frac{e'}{\tau^2} + \frac{e''}{\tau^4} + \dots\dots\right) \quad . \quad . \quad . \quad (4)$$

V being the velocity, and V_0, ϵ, etc. constants, while for ψ, the rotation produced by a length z of the substance, he finds

$$\psi = \frac{f}{\tau^2}\left\{1 + \frac{f'}{\tau^2} + \frac{f''}{\tau^4} + \dots\dots\right\} \quad . \quad . \quad (5)$$

For the explanation of double refraction Boussinesq supposes that the constants in the above formula giving U, V, W in terms of u, v, w may be functions of the direction of displacement; but, arguing from the relative importance of A, C, and D in the ordinary theory of refraction (refraction is due to the existence of A, dispersion only to that of D), he supposes that we may to a first approximation treat C and D as constants, while we consider A as a function of the direction, and write for the three axes of symmetry, the existence of which is assumed, the values $A(1 + \alpha)$, $A(1 + \beta)$, and $A(1 + \gamma)$.

This leads to the equations—

$$\left.\begin{aligned} \frac{d^2u}{dt^2} &= K(1 + a)\frac{d\theta}{dx} + L(1 + a)\nabla^2 u \\ \frac{d^2v}{dt^2} &= K(1 + b)\frac{d\theta}{dx} + L(1 + b)\nabla^2 v \\ \frac{d^2w}{dt^2} &= K(1 + c)\frac{d\theta}{dx} + L(1 + c)\nabla^2 w \end{aligned}\right\} \quad . \quad . \quad (6)$$

K, L, a, b, c being functions of the other constants. It is clear that these are the same equations as were given by Lord Rayleigh,[1] and which have been already considered. The wave surface they lead to is not Fresnel's, at least if we suppose the vibrations to be necessarily transversal.

By retaining the terms involving the coefficient B, the elliptic polarisation produced by quartz in directions oblique to the axis is explained. The formula for the difference in velocity in the two elliptically polarised waves traversing the crystal in any given direction agrees closely with that given by MacCullagh. In this case the squares of the velocities parallel to the axis are given by the expression $N\left(1 \pm \frac{2\pi k}{\tau\sqrt{N}}\right)$, while the velocities in a direction making an angle θ with the axis depend on the equation

$$\omega^2 = N + \frac{M - N}{2}\sin^2\theta + \frac{2\pi^2k^2}{\tau^2}$$
$$\pm\frac{1}{2}\sqrt{\left[(M - N)^2\sin^4\theta + \frac{8\pi^2k^2}{\tau^2}\left\{2N + (M - N)\sin^2\theta\right\}\right]} \quad . \quad (7)$$

[1] See p. 179.

which can also be expressed in terms of the principal velocities at right angles to the axis, for if ω_1, ω_2 be the values of these, we have

$$\left.\begin{aligned} M + N &= \omega_1{}^2 + \omega_2{}^2 - \frac{4\pi^2 k^2}{\tau^2} \\ (M - N)^2 &= (\omega_1{}^2 - \omega_2{}^2)^2 - \frac{8\pi k^2}{\tau^2}(\omega_1{}^2 + \omega_2{}^2) \end{aligned}\right\} \quad . \quad (8)$$

The laws obtained in this paper are further developed in a second and third in the same journal. In this third paper, Boussinesq [1] points out the necessity of including in the expression for U in terms of u differential co-efficients of u, v, w with respect to the time, and shows that the phenomena of magnetic rotation can be accounted for by putting in the case of a wave travelling parallel to z—

$$\left.\begin{aligned} U &= Au - \mathfrak{B}\frac{dv}{dt} \\ V &= Av + \mathfrak{B}\frac{du}{dt} \\ W &= Aw \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (9)$$

while the phenomena presented by refraction at the surface of a moving body are explained on the supposition that in finding d^2U/dt^2 we have to take into account the visible motion of the body, and write

$$\frac{d}{dt} = \left(\frac{d}{dt} + L\frac{d}{dx} + M\frac{d}{dy} + N\frac{d}{dz}\right) \quad . \quad . \quad . \quad (10)$$

L, M, N being the components of the velocity at the point x, y, z; it is shown that in cases in which L, M, N are small compared with ω', the apparent velocity of light in the body is

$$\omega' = \omega + \frac{\mu^2 - 1}{\mu^2}\overline{V},$$

μ being the refractive index and $\overline{V}$ the velocity of the body in the direction in which the light is travelling. This, of course, is the formula given by Fresnel.

§ 3. M. de St. Venant,[2] in the article already quoted, sums up his criticism of the theory as follows: 'Les deux hypothèses principales de cette théorie nouvelle me semblent bien près de s'élever à la hauteur de choses démontrées.' At the same time there remains the difficulty pointed out by Sarrau [3] of explaining on mechanical principles how the various terms in U, V, W arise, and on what physical phenomena the mechanical forces brought into action depend.

§ 4. A further step in the progress of the theory was brought about by the discovery of anomalous dispersion by Christiansen [4] in 1870. Le

Roux [1] had found that vapour of iodine refracted red light more strongly than violet, and Christiansen, in the paper quoted, announced the result that for a solution of the aniline dye fuchsin in alcohol the refractive index increases from the Fraunhofer line B to D, then sinks rapidly as far as G, and increases again beyond. The experimental investigation of the subject was continued by Kundt,[2] who proved that this anomalous dispersion was marked in all substances showing strong surface coloration, and that there was an intimate relation between it and the absorptive power of the substance. As the result of his experiments, Kundt was able to lay down the rule that in going up the spectrum, from red to violet, below an absorption band the deviation is abnormally increased by the absorption, while above the band the deviation is abnormally decreased. Kundt has been able to see this abnormal effect produced by the absorption of sodium light.

On the old theory of dispersion, as developed by Cauchy and others, this effect was inexplicable. Boussinesq, it is true, had explained the phenomena in vapour of iodine by saying that it implied that the coefficient D was positive; and here, in a way, lay a germ of the truth, for the mutual reaction theory lends itself readily to a partial explanation of the whole.

§ 5. Such an explanation was first given by Sellmeyer. He had been led to expect the effect from theoretical reasons in 1866,[3] and had endeavoured to discover it in a fuchsin solution, but without success. The action between the ether and matter is a periodic one of the same period as the light-wave traversing the ether. Owing to the enormous density of the matter compared with the ether its motion will in general be negligeably small; but if it should happen that the period of the natural vibrations of the matter particles coincides with that of the incident disturbance this will no longer be the case. The energy of the light-vibration will be absorbed by the matter, and this absorption will tend to react on the light-disturbance, and will, it can be shown, increase the refractive power of the medium for disturbances of greater period than the critical one, and decrease it for disturbances of less period.

The problem is much the same as that of a pendulum the point of support of which is undergoing a small periodic disturbance. If the period of the disturbance be greater than that of the natural vibration of the pendulum the reaction of the pendulum on its support will tend to quicken the motion of the latter, and *vice versâ.*

Sellmeyer, in the papers referred to,[4] published in 1872, after a most clear and able discussion of the difficulties of the elastic solid theories, adopts the hypothesis that the ponderable atoms vibrate, but with much smaller amplitudes than the ether particles. He then proceeds to consider the mechanism by which this is brought about. As with Boussinesq, the ether is supposed to have the same rigidity and density everywhere. The ether particles act directly on the matter particles, and in consequence of the vibrations of the former the equilibrium positions of the latter are

[1] *Ann. de Chim.* S. III. t. xli. p. 285.

disturbed and execute small harmonic vibrations; but the matter particles themselves will not generally coincide with their positions of instantaneous rest, and so we have to consider their vibrations about these positions. The equilibrium position of the matter at any instant is made to depend on the configuration of the ether at that instant, and may clearly be expressed, under the given circumstances, as a simple harmonic function of the time, so that if ξ_0, η_0, ζ_0 be the equilibrium co-ordinates at time t of a given matter particle of mass m', we may put

$$\xi_0 = a_0 \sin 2\pi \frac{t+\alpha}{\tau} \quad . \quad . \quad . \quad . \quad (11)$$

The amplitude a_0 will be very small.

The force acting on the particle m' is then considered on the assumption that the action between two particles of ether and matter respectively depends solely on the distance, and may be expressed by $mm'f(r)$, and it is shown that, supposing that $f(r)$ is a continuous function of the co-ordinates,[1] the force per unit mass tending to draw m' to its instantaneous position of equilibrium is

$$X = \frac{4\pi^2}{\delta^2}(\xi - \xi_0) \quad . \quad . \quad . \quad . \quad (12)$$

where δ is a quantity depending on f and the configuration of the medium, which may be a function of the direction. Thus, for an isotropic medium we have as the equation of motion of the matter particles—

$$\frac{d^2\xi}{dt^2} = -\frac{4\pi^2}{\delta^2}\left\{\xi - a_0 \sin \frac{2\pi}{\tau}(t+\alpha)\right\},$$

which leads, of course, to the integral

$$\xi = \frac{\tau^2}{\tau^2 - \delta^2} a_0 \sin \frac{2\pi}{\tau}(t+\alpha) + b \sin \frac{2\pi}{\delta}(t+\beta) \quad . \quad . \quad (13)$$

except when $\tau = \delta$, when

$$\xi = -\pi \frac{\delta}{t} a_0 \cos \frac{2\pi}{\delta}(\tau + \alpha) + b \sin \frac{2\pi}{\delta}(t+\beta) \quad . \quad . \quad (14)$$

The question as to the legitimacy of the assumption involved in the equation

$$\xi_0 = a_0 \sin \frac{2\pi}{\tau}(t+\alpha)$$

is then discussed, and it is finally shown that it is correct.

Again, it follows with great probability, from the experiments of Fizeau and Foucault [2] on interference with long difference of path, that in a ray of light the amplitude of vibration resolved in a given direction is not constant. We have, therefore, to treat a_0 as varying—slowly, it is true, compared with the rapidity of the vibrations—but still, it is probable, passing through many series of changes in one second.

This leads to the result that b, the amplitude of the natural vibrations

[1] See Stokes, *Brit. Assoc. Report*, 1862, p. 261.
[2] *Ann. de Chim.* s. iii. t. xxvi. p. 138.

of the matter particle, will always be small unless $\tau=\delta$. Omitting, then, these from consideration, it follows that

$$\xi=\frac{\tau^2}{\tau^2-\delta^2}\xi_0 \quad . \quad . \quad . \quad . \quad . \quad . \quad (15)$$

and the vibrations thus set up in the matter are shown to be the cause of refraction; while if $\tau=\delta$ we have

$$\left.\begin{aligned}\xi&=-a\cos 2\pi\frac{t}{\delta}\\ \frac{da}{dt}&=\frac{\pi}{\delta}a_0\end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad (16)$$

and these vibrations are the cause of absorption.

So far, then, the results of this investigation agree with those Boussinesq has given. They are, however, more general, in that they contemplate the possibility of the motions of the matter particles becoming appreciable, and so producing absorption. The next paper considers the question of the manner in which the action between the matter and ether affects the velocity of light. At first the direct effect of the matter on the ether is neglected, and the refractive power of the substance is found by considering the energy lost by the ether and gained by the matter in each vibration. The refractive power is measured by n^2-1, where n is the refractive index.

Now consider a volume so small that all the ether particles in it may be treated as in the same phase, so large that it contains many matter particles, and suppose the reactions considered confined to the ether and matter of this element.

Then it can be shown that if m' be the density of the ether, a' the amplitude of its vibration, the energy lost by the ether is $(n^2-1)2\pi^2m'a'^2/\tau^2$, while that gained by the matter is $2\pi^2\{\Sigma m\tau^2a_0{}^2/(\tau^2-\delta^2)\}/\tau^2$, whence the important formula

$$n^2-1=\frac{\Sigma m\dfrac{\tau^2}{\tau^2-\delta^2}a_0{}^2}{m'a'^2} \quad . \quad . \quad . \quad . \quad . \quad (17)$$

is obtained.

We may write this—

$$n^2-1=\Sigma\frac{K}{\dfrac{1}{\delta^2}-\dfrac{1}{\tau^2}} \quad . \quad . \quad . \quad . \quad . \quad . \quad (18)$$

where by Σ we mean that all the possible values of δ, the free period of the matter particles, are to be taken into consideration. Now let us suppose that τ is greater than δ, and that the matter particles have only one free period, then the denominator of the fraction is positive, and decreases as τ approaches δ. The refractive power, therefore, increases as the period decreases (*i.e.*, as we go up the spectrum), and as τ approaches the critical value δ (*i.e.*, as we near the absorption band) the refractive power is abnormally increased. Above the absorption band, supposing there be but one, the fraction is negative, and decreases numerically in value as τ is still further decreased; and until τ reaches a value for which $1/\tau^2=1/\delta^2+K$, n is imaginary.

As τ decreases still further the refractive power increases, but the refractive index is less than unity.

The presence of a second absorption band above the first will, of course, modify the conclusions. The change in refractive power is perhaps best illustrated by a curve, as is done in Sellmeyer's paper. For the case above considered take values of the refractive power (n^2-1) for ordinates, and the reciprocals of the periods for abscissæ, then the equation in the case of one absorption band will be

$$y = \frac{K}{a-x},$$

where $a = 1/\delta^2$.

Thus the curve is an hyperbola, with the axis of x and the line $x = a$ as asymptotes. If there be two absorption bands we have

$$y = \frac{K}{a-x} + \frac{L}{b-x},$$

and in this case there would be two critical values for x (viz., a and b) for which the refractive power would become infinite, and near which the dispersion would be anomalous.

In 1874 there appeared a paper by Ketteler[1] on the same subject. In an earlier paper he had enunciated as the law of dispersion in a gas the formula

$$n^2 - 1 = \frac{\alpha}{1 - \frac{\beta^2}{l^2}},$$

l being the wave length and α, β constants.

Further comparison with experiments had led him to the formulæ

$$\frac{1}{n^2} = K\,l^2 + A + \frac{B}{l^2 - C}$$

and he now shows that by a proper interpretation of the constants this will include the case of abnormal dispersion.

§ 6. The theory of the mutual reaction between the matter and ether was next developed by Helmholtz, and his work was continued by Lommel, Ketteler, and Voigt. The method adopted by Ketteler differs somewhat from those of the other three. Helmholtz[2] (in 1875), Lommel[3] (in 1878), and Voigt[4] (in 1883) start in the same manner to form the simultaneous equations satisfied by the displacements of the ether and matter particles in a given element of volume. Let u, v, w be the displacements of the ether particles of density m in an element of volume δv, U, V, W those of the matter particles of density μ.

The forces on m are, as in Boussinesq's paper referred to above,[5] considering only the components parallel to the x axis:—

[1] Ketteler, 'Das specifische Gesetz der sogenannten anomalen Dispersion,' *Pogg. Ann.* Jubelband, p. 166. See also p. 181.

[2] Helmholtz, 'Zur Theorie der anomalen Dispersion,' *Pogg. Ann.* t. 154, p. 582.

[3] Lommel, 'Theorie der normalen und anormalen Dispersion,' *Wied. Ann.* t. iii. p. 339.

[4] Voigt, 'Theorie des Lichtes für vollkommen durchsichtige Medien,' *Wied. Ann.* t. xix. p. 873.

[5] See p. 213.

(1) X', arising from external impressed forces;
(2) X, arising from the action of the other ether particles external to the element δv;
(3) A, arising from the action of the matter.
While for μ, the matter particle, they are:—
(1) Ξ', arising from external impressed forces;
(2) Ξ, arising from the action of the matter external to the element;
(3) A, arising from the direct action of the ether.
So that the equations of motion for an isotropic medium are—

$$\left.\begin{array}{l} m\dfrac{d^2u}{dt^2} = X' + X + A, \text{ etc.} \\ \quad \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \\ m'\dfrac{d^2U}{dt^2} = \Xi' + \Xi + \mathrm{A}, \text{ etc.} \\ \quad \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \end{array}\right\} \quad . \quad . \quad . \quad (19)$$

In all three theories the impressed forces are supposed to vanish, so that $X' = \Xi' = 0$. The action between the matter and ether is supposed to be confined to the element of volume considered—*i.e.* the dimensions of the element are treated as large compared with the distance at which the direct action of an ether particle on a matter particle is sensible.

This leads to the relation[1] $A + \mathrm{A} = 0$, independently of the value of A.

The term X springs from the ordinary elastic reaction of the ether. Helmholtz and Lommel, considering only a wave of displacement in the direction of x travelling parallel to z, write for this term

$$a^2\frac{d^2u}{dz^2},$$

while Voigt considers the general forms of the expression given by the ordinary elastic solid theory, which, of course, reduces for the case of an isotropic medium to

$$e\nabla^2u + e'\frac{d\delta}{dx},$$

where

$$\delta = \frac{du}{dx} + \frac{dv}{dy} + \frac{dw}{dz}.$$

For the forces represented by Ξ, Voigt again considers the general case of a strained elastic solid, while Helmholtz and Lommel after him write

$$\Xi = -a^2U - \gamma^2\frac{dU}{dt}.$$

For the proper values to be given to A and A there is great divergence of opinion shown in the three theories.

[1] In his paper Lommel—as has been pointed out by Ketteler, 'Optische Controversen,' *Wied. Ann.* t. xviii. p. 387, and Voigt, 'Bemerkungen zu Herrn Lommel's Theorie des Lichtes,' *Wied. Ann.* t. xvii. p. 468—really employs the condition $A - \mathrm{A} = 0$, for he estimates u and U in opposite directions. In his reply, *Wied. Ann.* t. xix. p. 908, Lommel endeavours to justify the signs used, but I think without success. The effect will be to change the sign of a coefficient in one of the terms.

Helmholtz supposes, 'um die Bewegungsgleichungen zu vervollständigen,' that A is proportional to the relative displacement of the ether and atoms in the element of volume, and writes, therefore,

$$A = \beta^2(U - u).$$

Lommel supposes that the action 'follows Newton's law of friction,' and depends on the relative velocity of the two; he puts, therefore,

$$A = \beta^2 \frac{d}{dt}(U - u).$$

The expression given by Voigt is much more complicated, and can best be considered later. Thus the equations we have to deal with are—

$$\left.\begin{aligned} m\frac{d^2u}{dt^2} &= a^2\frac{d^2u}{dz^2} + \beta^2(U-u) \\ \mu\frac{d^2U}{dt^2} &= -\beta^2(U-u) - a^2U - \gamma^2\frac{dU}{dt} \end{aligned}\right\} \quad . \quad . \quad (20)$$

(Helmholtz), and

$$\left.\begin{aligned} m\frac{d^2u}{dt^2} &= a^2\frac{d^2u}{dz^2} + \beta^2\frac{d}{dt}(U-u) \\ \mu\frac{d^2U}{dt^2} &= -\beta^2\frac{d}{dt}(U-u) - a^2U - \gamma^2\frac{dU}{dt}^* \end{aligned}\right\} \quad . \quad . \quad (21)$$

(Lommel).

The method of solution is the same in both. u and U, which, strictly, are the displacements of ether and matter in the same volume in the displaced condition, are treated as if they were the displacements of ether and matter having the same undisturbed co-ordinates x, y, z. This is legitimate, for U and u are both taken to be functions of the position of the wave front and the time only, and hence for all points on the same wave front U has at a given instant the same value.

Assume, then,

$$\left.\begin{aligned} u &= \mathfrak{A}e^{-kz+in(z-ct)/c} \\ U &= Ae^{-kz+in(z-ct)/c}\dagger \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (22)$$

k is the coefficient of absorption, c the velocity, and $2\pi/n$ the period of the vibration.

On substituting these values in Helmholtz's equations, we find

$$\frac{1}{c^2} - \frac{k^2}{n^2} = \frac{m}{a^2} - \frac{\beta^2}{a^2n^2} - \frac{\beta^4}{a^2n^2}\frac{\mu n^2 - a^2 - \beta^2}{(\mu n^2 - a^2 - \beta^2)^2 + \gamma^4 n^2} = F \text{ (say)} \quad . \quad (23)$$

and

$$\frac{2k}{cn} = \frac{\beta^4\gamma^2}{a^2n}\frac{1}{(\mu n^2 - a^2 - \beta^2)^2 + \gamma^4 n^2} = G \text{ (say)} \quad . \quad . \quad (24)$$

* In this equation the sign of β^2 has been changed from that given by Lommel in accordance with the remark on p. 221; but see Lommel's reply to Voigt, *Wied. Ann.* t. xix. p. 908.

† A, of course, no longer has the same meaning as above, but is the amplitude of the matter vibrations.

To solve these, put

$$\frac{1}{c} = \rho \cos \omega,$$

$$\frac{k}{n} = \rho \sin \omega.$$

Then

$$\left.\begin{aligned} \frac{1}{c^2} - \frac{k^2}{n^2} &= \rho^2 \cos 2\omega = F \\ \frac{2k}{cn} &= \rho^2 \sin 2\omega = G \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (25)$$

Thus the value of k, on which the absorption depends, is proportional to γ^2, the coefficient of dU/dt in the equation, and vanishes if γ^2 is zero; that is, if there be no frictional resistance to the matter motion. If k be at all appreciable, the light-disturbance will penetrate but a little way into the medium, so that for transparent media we may treat k, and therefore G, as small.

In this case we have

$$\frac{1}{c^2} = F + \frac{1}{4}\frac{G^2}{F} +, \text{ etc.},$$

while in the small term we may put for G/F the value $2kc/n$.

In these circumstances, then,

$$\frac{k}{c} = \frac{1}{2} nG = \frac{\beta^4\gamma^2}{2\alpha^2\mu^2} \cdot \frac{1}{(n^2 - \nu^2)^2 + 4(\nu^2 + \varpi^2)\varpi^2} \quad . \quad . \quad (26)$$

where

$$\left.\begin{aligned} \mu\nu^2 &= \alpha^2 + \beta^2 - \gamma^4/2\mu \\ \varpi^2 &= \gamma^4/4\mu^2 \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (27)$$

Thus, as n changes k/c is a maximum when $n = \nu$; if the corresponding values of k and c be k_0 and c_0, then

$$\frac{c_0}{k_0}\left\{1 + \frac{(n^2 - \nu^2)^2}{4\varpi^2(\nu^2 + \varpi^2)}\right\} = \frac{c}{k} \quad . \quad . \quad . \quad (28)$$

If the value of γ be zero, then, for $n = \nu$, k is infinite compared with c; all the light is absorbed.

At the same time A is large, and we have, in dealing with the motion of the matter particles, to consider the limit of $Ae^{-k_0 z}$.

Turning, now, to the refraction, let C be the velocity of light in free space, N the refractive index, and suppose that the term $\frac{1}{4}G^2/F$ may be neglected, then

$$N^2 = C^2F = \frac{C^2 m}{\alpha^2}\left[1 - \frac{\beta^2}{mn^2} + \frac{\beta^4(\nu^2 + 2\varpi^2 - n^2)}{m\mu n^2\{(\nu^2 - n^2)^2 + 4\varpi^2(\nu^2 + \varpi^2)\}}\right] \cdot \quad (29)$$

and the maxima and minima values of this expression lead to the limiting values of the refractive index.

These, it is shown, are given approximately by $n^2 - \nu^2 = \pm 2\nu\varpi$, which

correspond nearly to the maxima of absorption. Thus, as we go up the spectrum, the refractive power is a maximum for the value of n, given by $n^2 = \nu^2 - 2\nu\varpi$, and a minimum for $n^2 = \nu^2 + 2\nu\varpi$. There is, therefore, abnormal dispersion in the neighbourhood of the absorption band, but elsewhere the refractive index increases with n. Again, for large values of n we have $N^2 = C^2 m/a^2$. Now, if the density and the rigidity of the ether be the same in all bodies, we should have $C^2 = a^2/m$, and therefore in this case $N = 1$. Thus the light of shortest wave lengths would be transmitted without refraction, contrary to experimental results. Sellmeyer, however, pointed out a method of explaining this difficulty which would be consistent with the supposition that C^2 is equal to a^2/m. According to him, we must suppose that there is a strong absorption band somewhere just above the visible limits of the spectrum—that is to say, that the value of $\nu^2 - 2\nu\varpi$ is just beyond the limits of the visible spectrum, and that owing to this the refraction below the band is abnormally increased.

The paper closes with a method for constructing the form of the refraction and absorption curves.

Lommel's equations can be solved in a similar manner, and lead to similar formulæ. The two theories can best be compared with each other and with experiment by changing the notation slightly, and adopting that used by Ketteler[1] in his criticism of the same. Let us put, therefore,

$$\left.\begin{aligned} a^2 &= \mu\nu_1^{\,2} \\ \beta^2 &= B\nu_1^{\,2} \\ \gamma^2 &= \mu\nu_1 K \\ \nu_0^{\,2} &= \nu_1^{\,2}\left(1 + \frac{B}{\mu}\right) \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (30)$$

Then Helmholtz's equations (23) and (24) become

$$\frac{1}{c^2} - \frac{k^2}{n^2} = \frac{m}{a^2}\left[1 - \frac{B}{m}\frac{\nu_1^{\,2}}{n^2} + \frac{B^2\nu_1^{\,4}(\nu_0^{\,2} - n^2)}{\mu m n^2\{(\nu_0^{\,2} - n^2)^2 + n^2\nu_1^{\,2}K\}}\right] \quad . \quad (31)$$

and

$$\frac{2k}{cn} = \frac{m}{a^2}\,\frac{B^2\nu^5 K}{\mu m n\{(\nu_0^{\,2} - n^2) + n^2\nu_1^{\,2}K^2\}} \quad . \quad . \quad . \quad (32)$$

and if we suppose λ, λ_1, λ_0 to be the wave lengths corresponding to the periods n, ν_1, and ν_0, we find

$$\left.\begin{aligned} F &= \frac{m}{a^2}\left[1 - \frac{B\lambda^2}{m\lambda_1^{\,2}} + \frac{\dfrac{B^2}{\mu m}\dfrac{\lambda^4}{\lambda_1^{\,4}}\left(\dfrac{\lambda^2}{\lambda_0^{\,2}} - 1\right)}{\left(\dfrac{\lambda^2}{\lambda_0^{\,2}} - 1\right)^2 + K^2\dfrac{\lambda^2}{\lambda_1^{\,2}}}\right] \\ G &= \frac{m}{a^2}\,\frac{\dfrac{B^2}{\mu m}K\dfrac{\lambda^5}{\lambda_1^{\,5}}}{\left(\dfrac{\lambda^2}{\lambda_0^{\,2}} - 1\right)^2 + K^2\dfrac{\lambda^2}{\lambda_1^{\,2}}} \end{aligned}\right\} \quad . \quad . \quad (33)$$

[1] Ketteler, 'Optische Controversen,' *Wied. Ann.* t. xviii. p. 387.

while the ratio of the amplitudes is given by

$$A = \mathfrak{A}\frac{\frac{B}{\mu}\frac{\lambda^2}{\lambda_1^2}}{\sqrt{\left\{\left(\frac{\lambda^2}{\lambda_0^2}-1\right)^2+K^2\frac{\lambda^2}{\lambda_1^2}\right\}}} \quad . \quad . \quad . \quad (34)$$

We can give a sort of physical meaning to the constants in these formulæ as follows: λ_1 is the wave length of the natural vibrations of the matter, freed from any action of the ether; λ_0 is their wave length on the supposition that the action between the ether and matter is proportional to the displacement, while the ether remains fixed; while ν_1 and ν_0 are the frequencies of these vibrations. B vanishes when there is no matter present, and since the expression shows that B/m is a number, it is probable that B will be proportional to the matter density; while K is a number on which the strength of the frictional retardation depends.

The quantity λ_1, the wave length of the free vibrations (*i.e.* the distance the light-wave travels in a natural free matter period) is immensely great compared with λ, so that A is small compared with $\mathfrak{A}$, except in the cases in which λ does not differ greatly from λ_0.

It will be seen at once that the formula for F, on which, when the absorption is small, the refractive index depends, in terms of the wave length is very complicated. I am not aware that any attempts have been made to compare it carefully with theory.

In the cases in which K is small (*i.e.*, for transparent media) λ_0 will be an approximate lower limit to the wave length of the light transmitted.

If we integrate the equation given by Lommel's hypothesis, modified so as to agree with the principle of action and reaction, we find

$$F^* = \frac{m}{a^2}\left[1 - \frac{\frac{B'^2}{m\mu}\frac{\lambda^2}{\lambda_1^2}\left(\frac{\lambda^2}{\lambda_1^2}-1\right)}{\left(\frac{\lambda^2}{\lambda_1^2}-1\right)^2+\left(\frac{B'}{\mu}-K\right)^2\frac{\lambda^2}{\lambda_1^2}}\right] \quad . \quad . \quad . \quad (35)$$

where B′ is a constant related to the β^2 of Lommel's equations in the same manner as B is to β^2 above. If, however, we take Lommel's expression strictly, to which he still adheres,[1] the sign of the fractional expression must be changed.

If we retain the negative sign the formula (35) fails to represent the facts. Neglecting for a moment the effect of absorption, and supposing the ether to be of the same rigidity and density as in free space, the square of the refractive index will be rather less than unity for the longest waves; it will then decrease to a minimum value, which will be positive, and then rise rapidly through the absorption band, for which $\lambda = \lambda_0$, reaching a maximum a little above the band, from which it will again fall. Absorption effects will only slightly modify these conclusions. Thus the spectrum above the band ought to be more refracted than that below, and except just near the band the refractive index should decrease as the wave length decreases. This is fatal to the theory in this form. In its

* This becomes the expression given by Lommel on substituting $B'/\mu - K = \epsilon^2$, $\lambda_1 = \lambda_0$, $B' = m(K-\epsilon)$, and interchanging m and μ.

[1] Lommel, 'Zur Theorie des Lichtes,' *Wied. Ann.* t. xix. p. 908.

original form it is not open to this criticism, and accounts for the facts, but its fundamental equations are hopelessly at variance with Newton's third law, so long, at least, as we suppose the mutual reaction limited to that between the matter and ether in the element of volume considered —that is, so long as we may suppose that there are many molecules in an element of volume. The original formula for dispersion leads to results which, as Lommel[1] has shown, agree fairly with experiment; and by carrying the approximation a step further the agreement becomes closer still, so that his fundamental equations might be taken as an empirical representation of the facts with some approach to the truth.

Voigt's theory differs from these mainly in the values assigned to A and A and the methods by which those values are obtained; and before treating at length of it, it will conduce to clearness if we consider Ketteler's theory, the results of which have considerable resemblance to the two already mentioned, while the work itself is earlier than Voigt's.

§ 7. Ketteler[2] is the author of a large number of papers on this subject, and the form in which he has presented his theory has varied somewhat, though the central idea which he has endeavoured to express has remained the same throughout. The idea seems to be as follows. The exact expression of the action between matter and ether, the A and A of the fundamental equations, is unknown to us, and we must therefore endeavour to eliminate it from the equations. This we can effect by considering the work done per unit time on the whole system, into which, of course, the mutual reactions will not come, and equating it to the rate of change of the kinetic energy. This alone, of course, will only lead to one equation, and though in some of his work Ketteler appears to obtain two out of it, this, as we shall see shortly, is done by the aid of an additional hypothesis.

It is, however, not till some of the later papers that these views are completely developed. In his first paper[3] he assumes that the action of the matter on the ether is to increase its rigidity by the quantity ϵa, and to introduce a resistance $a\kappa\rho$, where ϵ is constant for the medium and a is some unknown function of its dynamical condition, while the forces on the matter are $a(\epsilon'\nabla^2\rho' + \kappa'\rho')$, ρ' being the matter displacement, so that, considering the motion parallel to x, we have for the ether

$$m\frac{d^2\rho}{dt^2} = (e + \epsilon a)\frac{d^2\rho}{dx^2} + a\kappa\rho$$

and for the matter

$$m'\frac{d^2\rho'}{dt^2} = a\left(\epsilon'\frac{d^2\rho'}{dx^2} + \kappa\rho'\right) \qquad . \quad . \quad . \quad (36)$$

Arguments similar to those employed by Sellmeyer lead to the equation

$$\mathrm{N}^2 - 1 = \frac{m'\rho'^2}{m\rho^2} \qquad . \quad . \quad . \quad . \quad . \quad (37)$$

and on multiplying the first of the equations of motion by ρ, the second

[1] Lommel, 'Ueber das Dispersionsgesetz,' *Wied. Ann.* t. xiii. p. 353.

[2] Since the above was sent to press, Ketteler has published his optical theories in the form of a book, *Theoretische Optik*: Braunschweig, F. Vieweg und Sohn, 1885. The fundamental equations are formed as indicated below (Equation 43), and the remarks made in connection with that section apply.

[3] Ketteler, 'Versuch einer Theorie der (anomalen) Dispersion des Lichtes in einfach- und doppelt-brechenden Medien,' *Carl Repertorium*, t. xii. p. 322.

by ρ', we find that the condition (37) requires the coefficient of a to vanish separately, and we are led to the two equations

$$\left.\begin{aligned} m\rho\,\frac{d^2\rho}{dt^2} + m'\rho'\,\frac{d^2\rho'}{dt^2} &= e\rho\,\frac{d^2\rho}{dx^2} \\ \rho\left(\epsilon\frac{d^2\rho}{dx^2} + \kappa\rho\right) + \rho'\left(\epsilon'\frac{d^2\rho'}{dx^2} + \kappa'\rho'\right) &= 0 \end{aligned}\right\} \quad . \quad . \quad (38)$$

and these are the two fundamental equations of the theory, from which an expression is found for the refractive index in terms of the wave lengths and constants, viz. :—

$$N^2 = N^2_{\infty} + \Sigma\,\frac{D}{\frac{\lambda^2}{\lambda_1{}^2} - 1} \quad . \quad . \quad . \quad . \quad . \quad (39)$$

where the Σ must be taken to include the different kinds of matter particles in the medium. So far, at any rate, the theoretical bases of these expressions are no more secure than those of Lommel and Helmholtz. The dispersion equation, however, is much more simple than that given by Helmholtz, and agrees well, as Ketteler [1] has himself shown, with experiment.

A second paper [2] develops some further consequences and traces the form of the dispersion curve in various circumstances.

In a third paper [3] the principles of the theory are stated and applied to doubly refracting media, but the equations from which he starts—the same as those given above, only written with three co-ordinates—do not express the physical facts which they are intended to do, and the theory deduced can only be considered as empirical.

A further attempt, based on this principle of energy alone, is made in a more recent paper [4] to establish two independent equations. Thus, the ether mass in an element being displaced a distance ds, the matter mass ds'; then the equation

$$m\,\frac{d^2\rho}{dt^2}\,ds + m'\,\frac{d^2\rho'}{dt^2}\,ds' = e\,\frac{d^2\rho}{dz^2}\,ds \quad . \quad . \quad . \quad (40)$$

is supposed to express the law of the conservation of energy for the ether motion; it neglects entirely the forces on m' from the action of neighbouring matter. The conservation of energy principle alone will give but one equation when applied to the system, though it will of course eliminate the unknown reactions between matter and ether.

Similar remarks must be made with regard to other papers [5] dealing with the formation of the fundamental equations. The equations D of the last article referred to are only true on the assumption that the

reaction of the matter on the ether produces a force $-m'C'\frac{d^2\rho'}{dt^2}$,* while the action of the ether on the matter is expressed by a force $-mC\frac{d^2\rho}{dt^2}$; and, indeed, in his most recent work on the subject [1] he realises clearly that the energy principle only leads him to one equation, viz. :—

$$m\frac{d^2\rho}{dt^2}d\rho + m'\frac{d^2\rho'}{dt^2}d\rho' = e\nabla^2\rho d\rho - \kappa\rho' d\rho' \quad . \quad . \quad (41)$$

e being the rigidity of the ether in free space—and then combines with this a 'second equation relating to the special mode of action of the matter particles, which can be no other than the renowned fundamental equation of Bessel's theory of the pendulum'; this may be written

$$m\frac{d^2\rho}{dt^2}C + m'\frac{d^2\rho'}{dt^2} = -\kappa\rho' \quad . \quad . \quad . \quad . \quad . \quad (42)$$

It is then further assumed that the matter particles exert a force $\beta m'\rho'$ on the ether, and the equations finally become—

$$\left.\begin{aligned} m\frac{d^2\rho}{dt^2} - m'C_0\frac{d^2\rho'}{dt^2} &= e\nabla^2\rho + \beta m'\rho' \\ m'C_0\frac{d^2\rho}{dt^2} + m'\frac{d^2\rho'}{dt^2} &= -\left(\kappa\rho' + \gamma\frac{d\rho'}{dt}\right) \end{aligned}\right\} \quad . \quad . \quad (43)$$

leading to the equation

$$\left. N^2 - N^2_\infty = \frac{N^2_\infty - N_0^2 + \sqrt{-1}(N^2_\infty - 1)K\frac{\lambda}{\lambda_1}}{\frac{\lambda^2}{\lambda_1^2} - 1 - \sqrt{-1}K\frac{\lambda}{\lambda_1}}\right\} \quad . \quad . \quad (44)$$

where K is a quantity depending on γ. When K is small, as is always the case in transparent media, this becomes the formula already mentioned, which has been tested over so wide a range by Ketteler. It is clear from these last equations that the action of the matter on the ether is represented by $m'C_0\frac{d^2\rho'}{dt^2} + \beta m'\rho'$, and of the ether on the matter by $m'C_0\frac{d^2\rho}{dt^2}$. It is difficult to conceive of the mechanical principles which would lead to these terms as they stand, and the occurrence of the imaginary quantity in the expression for the refractive index, to which they lead, is a blot on the theory.

§ 8. In fact, the form of the equations given in his earlier papers [2] leads to results which are more directly intelligible, while the equations themselves can, it seems to me, be established by the aid of a suggestion due to Ketteler himself ('Eine dritte Annahme,' p. 397).

For, taking the notation employed when considering Helmholtz and

* In Ketteler's paper ξ, ξ' are used for the displacements. I have retained ρ, ρ', in accordance with the notation already employed.

[1] 'Zur Dispersionstheorie des Lichtes,' *Wied. Ann.* t. xxi. p. 199. See also Ketteler, *Theoretische Optik*, p. 85, *et seq.*

[2] Ketteler, 'Optische Controversen,' *Wied. Ann.* t. xviii. p. 387.

Lommel, let us assume, according to this third supposition of Ketteler's, that the reaction between the ether and matter is proportional to the relative accelerations of the two. Helmholtz supposes it proportional to the relative displacements, Lommel to the relative velocities. In this case, then,

$$A = -\beta^2 \frac{d^2}{dt^2}(u - U),$$

and hence

$$m\frac{d^2u}{dt^2} + \beta^2\frac{d^2}{dt^2}(u - U) = X,$$

$$\mu'\frac{d^2U}{dt^2} - \beta^2\frac{d^2}{dt^2}(u - U) = \Xi,$$

Thus

$$m\frac{d^2u}{dt^2} - \frac{\beta^2 m}{m+\beta^2}\frac{d^2U}{dt^2} = \frac{mX}{m+\beta^2} \quad . \quad . \quad . \quad (45)$$

$$\frac{\mu\beta^2}{\mu-\beta^2}\frac{d^2u}{dt^2} + \mu\frac{d^2U}{dt^2} = \frac{\mu}{\mu-\beta^2}\Xi \quad . \quad . \quad . \quad (46)$$

And, with Ketteler's assumptions as to the forces X and Ξ, these may be written as follows—

$$\left.\begin{aligned} m\frac{d^2u}{dt^2} + \mu C'\frac{d^2U}{dt^2} &= a^2\frac{d^2u}{dz^2} \\ \mu C\frac{d^2u}{dt^2} + \mu\frac{d^2U}{dt^2} &= -\left(a^2U + z^2\frac{dU}{dt}\right) \end{aligned}\right\} \quad . \quad . \quad . \quad (47)$$

which are the same in form as Ketteler's equations, though a^2 is not the rigidity of the free ether, while there is a relation between C and C′, for

$$\left.\begin{aligned} C' &= -\frac{m}{\mu}\frac{\beta^2}{m+\beta^2} \\ \text{and} \qquad C &= \frac{\beta^2}{\mu-\beta^2} \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (48)$$

However, this does not matter, for it is the product CC′ which comes into the fundamental equations of the solution, and we find

$$\frac{1}{c^2} - \frac{k^2}{n^2} = F = \frac{m}{a^2}\left[1 + \Sigma\frac{D\left(\frac{\lambda^2}{\lambda_1^2} - 1\right)}{\left(\frac{\lambda^2}{\lambda_1^2} - 1\right)^2 + K^2\frac{\lambda^2}{\lambda_1^2}}\right] \quad . \quad . \quad (49)$$

$$\frac{2k}{cn} = \frac{m}{a^2}\Sigma\frac{DK\frac{\lambda}{\lambda_1}}{\left(\frac{\lambda^2}{\lambda_1^2} - 1\right)^2 + K^2\frac{\lambda^2}{\lambda_1^2}} \quad . \quad . \quad . \quad (50)$$

where $D = CC'$, and K is proportional to γ^2.

The quantity a^2/m is no longer the square of the velocity in free space, and cannot be put equal to unity, and, in fact, a^2/m will be the square of the refractive index for very long waves. Ketteler (p. 398)

seems to consider it an objection to his theory that it gives a value differing from unity to the refractive index for infinite waves, but the objection is not, I think, serious. As has been stated before, the dispersion equation given by his theory has been repeatedly tested by Ketteler,[1] and the agreement between theory and experiment is very satisfactory. Thus we may probably look upon this equation as one established empirically by his experiments, and while not agreeing with the reasoning employed by Ketteler in forming his equations of motion, may see in those equations the expression of a possible law of action between matter and the ether.

§ 9. Let us now turn to Voigt's work, which is of more recent date. He has been a severe critic of his predecessors, and objects strongly to various points in their work.

In his first paper[2] on the subject Voigt, following Boussinesq,[3] remarks that md^2u/dt^2 and $\mu d^2U/dt^2$ being quantities of the same order, U will be very small compared with u because μ is very large compared with m; it is therefore not necessary to introduce terms involving U into the differential equations for u. To this we may reply, (1) that it is quite possible that the coefficients of U and its differential coefficients involve μ the matter density, and that in consequence the terms in question are comparable with md^2u/dt^2, and (2) that in the critical case near the absorption band the value of U becomes large, and may be quite comparable with u.

Voigt also objects to the form adopted for Ξ in all the previous theories, viz. $-(\kappa U + \gamma dU/dt)$, pointing out that Helmholtz introduced the κU 'zur Vereinfachung der Rechnung,' and the $\gamma dU/dt$ to explain the transformation of light-energy into heat. If the ponderable matter is to be looked on as an elastic solid, then, according to Voigt, we ought to put for Ξ terms like $a^2\nabla^2 U + b^2 d\delta/dx$. To this Lommel replies[4] that the matter molecules each as a whole are not affected by the passage of the wave of light, but that intra-molecular or atomic motions are set up, and that the forces arising from these are represented by his terms, how he does not explain.

Of course, since it is assumed that $U = Ae^{kz + in(z-ct)/c}$, $\nabla^2 U = -(k + in/c)^2 U$, the difference between the two will only show itself in a change in the refraction formula.

The main criticism[5] of Ketteler's work relates to the method in which the equations are obtained. To this we have already referred.

§ 10. After these criticisms we turn to the consideration of Voigt's[6] own theory. His fundamental equations are, as we have seen,

[1] Ketteler, 'Constructionen zur anomalen Dispersion,' *Wied. Ann.* t. xi. p. 210; 'Einige Anwendungen des Dispersionsgesetzes auf durchsichtige, halbdurchsichtige und undurchsichtige Mittel,' *Wied. Ann.* t. xv. p. 336.

[2] 'Bemerkungen zu Herrn Lommel's Theorie des Lichtes,' *Wied. Ann.* t. xvii. p. 468.

[3] See p. 213.

[4] Lommel, 'Zur Theorie des Lichtes,' *Wied. Ann.* t. xix. p. 908.

[5] Voigt, 'Ueber die Grundgleichungen der optischen Theorie des Herrn E. Ketteler,' *Wied. Ann.* t. xix. p. 691; 'Duplik gegen Herrn Ketteler,' *Wied. Ann.* t. xxi. p. 534; Ketteler, 'Erwiederung auf Herrn Voigt's Kritik,' *Wied. Ann.* t xxi. p. 178; 'Duplik gegen Herrn Voigt,' *Wied. Ann.* t. xxii. p. 217.

[6] Voigt, 'Theorie des Lichtes für vollkommen durchsichtige Medien,' *Wied. Ann.* t. xix. p. 873.

$$\left.\begin{aligned} m\frac{d^2u}{dt^2} &= \mathrm{X} + \mathrm{X}' + A \\ \mu\frac{d^2\mathrm{U}}{dt^2} &= \Xi + \Xi' + \mathrm{A} \end{aligned}\right\} \quad . \quad . \quad . \quad (51)$$

X' and Ξ' are each put equal to zero, and the condition $A + \mathrm{A} = 0$ is assumed; that is, it is supposed, as we have stated before, that the sphere of action of each ether particle on the matter is small compared with the dimensions of the element of volume considered.

An expression is then found for the rate at which work is being done on the compound medium, and the condition formed that this expression should be a function of the time only.

So far as the terms depending on the mutual reactions are concerned, the rate of increase of the energy is given by

$$\left.\begin{aligned} \mathrm{S}_j' = \Sigma \int d(\text{vol.})_h \left(\mathrm{A}\frac{d(u-\mathrm{U})}{dt} + \mathrm{B}\frac{d(v-\mathrm{V})}{dt} + \mathrm{C}\frac{d(w-\mathrm{W})}{dt}\right) \\ + \Sigma \int d\,(\text{surface})_{hk}\, \mathrm{S}_{hk} = \mathrm{J}\,(\text{vol.}) + \mathrm{J}\,(\text{surface}) \end{aligned}\right\} \quad (52)$$

where the Σ implies that more than one medium may come into consideration, and the integrals are to extend over the whole volume of each separate medium and all the interfaces between the media, these being indicated by J (vol.) and J (surf.) respectively.

Forms are then found for A, B, C which make J (vol.) a complete differential coefficient with respect to the time, and at the same time lead to linear equations of motion which admit of solution in the form $u = \Sigma \mathrm{A} e^{(lx+my+nz+ct)}$. Four possible forms are found, which are given below.

$$\left.\begin{aligned} &(1) \quad -\mathrm{A}_1 = n_1(u-\mathrm{U}) + o_3(v-\mathrm{V}) + o_2(w-\mathrm{W}) \\ &(2) \quad \mathrm{A}_2 = p_3\frac{d(v-\mathrm{V})}{dt} - p_2\frac{d(w-\mathrm{W})}{dt} \\ &(3) \quad -\mathrm{A}_3 = r_1\frac{d^2(u-\mathrm{U})}{dt^2} + s_3\frac{d^2(v-\mathrm{V})}{dt^2} + s_2\frac{d^2(w-\mathrm{W})}{dt^2} \\ &(4) \quad \mathrm{A}_4 = q_3\frac{d^3(v-\mathrm{V})}{dt^3} - q_2\frac{d^3(w-\mathrm{W})}{dt^3} \end{aligned}\right\} \quad . \quad (53)$$

It will be noticed that (1) gives us Helmholtz's theory; (3) gives us Ketteler's in the modified form I have suggested; for an isotropic medium it is shown that the coefficients o and s vanish. Lommel's form is not included in the above; it is therefore, we see, inconsistent with the conservation of energy in the medium.

But there are other terms in the volume integral J (vol.) which will, when combined with suitable terms in the surface integral J (surf.), make the whole up to a differential coefficient of the time.

These terms are given by

$$-\mathrm{A} = \frac{d\mathrm{A}_x}{dx} + \frac{d\mathrm{A}_y}{dy} + \frac{d\mathrm{A}_z}{dz} \quad . \quad . \quad . \quad . \quad (54)$$

etc., and lead to terms in the volume integral

$$\int d\,(\text{vol.})\left[\mathrm{A}_x \frac{d^2(u-\mathrm{U})}{dtdx} + \mathrm{A}_y \frac{d^2(u-\mathrm{U})}{dtdy} + \mathrm{A}_z \frac{d^2(u-\mathrm{U})}{dtdz} + \ldots\right]$$
$$= \frac{df'}{dt} \text{ (let us suppose)} \quad . \quad (55)$$

Then f' is a function of $\frac{d(u-\mathrm{U})}{dx}$, etc., and four possible forms are found for A_x, etc., viz. putting χ, etc., for the differential coefficients $\frac{d(u-\mathrm{U})}{dx}$, etc.

(5) f'_5, a homogeneous function of $\chi_1 \quad . \quad . \quad . \quad \chi_9$

$$-(\mathrm{A}_x)_5 = \frac{df'_5}{d\chi_1}, \text{ etc.}$$

$$\text{Thus } -\mathrm{A}_x = \Sigma i n_{1i}\,\chi, \text{ etc.,}$$

$$\text{with } n_{ij} = n_{ji}.$$

(6) $$-\mathrm{A}_x = \Sigma p_{1i} \frac{d\chi_i}{dt}, \text{ etc.,}$$

$$\text{with the conditions } p_{ii} = 0,$$

$$p_{ij} = -p_{ji},$$

$$\text{giving } f'_6 = \text{constant}.$$

(7) $$-\mathrm{A}_x = \Sigma r_{1i} \frac{d^2\chi_i}{dt^2},$$

$$\text{with } r_{ij} = r_{ji},$$

$$\text{and } -2f'_7 = \Sigma\Sigma r_{ij} \frac{d\chi_i}{dt}\frac{d\chi_j}{dt}.$$

(8) $$-\mathrm{A}_x = \Sigma q_{1i} \frac{d^3\chi}{dt^3},$$

$$\text{with } q_{ii} = 0, \quad q_{ij} = -q_{ji},$$

$$\text{and } -f'_8 = \Sigma\Sigma q_{ij}\left(\frac{d^2\chi_i}{dt^2}\frac{d\chi_j}{dt} - \frac{d^2\chi_j}{dt^2}\frac{d\chi_i}{dt}\right).$$

We have thus eight possible forms of values for A, etc., all or any of which may occur in the equations. In the equations for the ether, U, V, W, being very small compared with u, v, w, are omitted.

An isotropic body is one in which no one direction differs in its properties from any other. For such a body it is supposed that the forces defined by 2, 4, 6, and 8 above do not exist, and a, a' being the coefficients in $-2f'_5$ and $-2f'_7$ respectively, it is shown that the equation for plane waves travelling parallel to z is—

$$(m+r)\frac{d^2u}{dt^2} = (e+a)\frac{d^2u}{dz^2} + a'\frac{d^4u}{dz^2dt^2} - nu \quad . \quad . \quad (56)$$

and hence,

$$\frac{1}{N^2} = \frac{\frac{m(e+a)}{e} - \frac{4a'\pi^2}{\lambda^2}}{m + r - \frac{n\lambda^2 m}{4e\pi^2}},$$

λ being the wave length in air and N the refractive index.

The complete value for A is—

$$A = -r\frac{d^2(u-U)}{dt^2} + a\frac{d^2(u-U)}{dz^2} + a'\frac{d^4(u-U)}{dz^2dt^2} - n(u-U) \quad . (57)$$

and in the above equation (56) U has been treated as small compared with u.

We see that the first and last terms are those given by the theories of Ketteler and Helmholtz respectively; Voigt's more general theory includes them as particular cases. The first and third terms occur in the theory developed by Boussinesq, which is also included in Voigt's.

In a further paper, in reply to some criticisms of Lommel, who argues that a wave propagated through the molecules of the medium must be a sound-wave, and that therefore the matter motion which affects the transmission of light must be *intra*-molecular not *inter*-molecular, Voigt shows,[1] by taking the matter motion into account, that the velocity of wave propagation in a medium constituted as supposed will be given by a quadratic equation. One root of this quadratic will be comparable with the velocity of light in this medium, the other with that of sound; while the ratio of the energy of the matter to that of the ether in the light-motion is the reciprocal of the same ratio in the sound-motion.

Voigt's theory applies only to perfectly transparent media, and its aim is to show that the optical properties of all such media can be explained on an elastic solid theory by considering the mutual reactions of two mutually interpenetrating elastic media. The author does not touch the problem of absorption, because for that purpose we require to deal with the molecular motion to which, in his opinion, heat effects are due, and these lie outside the domain of elastic solid theories. He does, however, deal with double refraction, circular and elliptic polarisation, and the various problems connected with reflexion and refraction. Most of these have been treated of also by Lommel and Ketteler.

Chapter II.—Double Refraction.

We will consider first the problem of double refraction. All three explain it in a similar manner. Within a crystal the action of the matter particles on the ether will depend on the direction of vibration, and some or other of the constants of the theory will be functions of this direction. It is assumed that the ether remains isotropic, and that there are three axes of symmetry, which are taken as those of the co-ordinates.

§ 1. Lommel[2] in his theory treats the constant we have denoted by a^2 as a function of the direction. β^2, which determines the action between ether and matter, and γ^2, on which the frictional effects depend,

[1] Voigt, 'Zur Theorie des Lichtes,' *Wied. Ann.* t. xx. p. 144.
[2] Lommel, 'Theorie der Doppelbrechung,' *Wied. Ann.* t. iv. p. 55.

are left invariable, so that the ether equations remain unaltered, and the matter equations become—

$$\mu\frac{d^2\mathrm{U}}{dt^2} = -\beta^2\frac{d}{dt}(\mathrm{U}-u) - a_1{}^2\mathrm{U} - \gamma^2\frac{d\mathrm{U}}{dt} \quad . \quad . \quad . \quad (58)$$

and similar equations with $a_2{}^2$ and $a_3{}^2$. It has been shown by him that for a transparent medium the velocity is given by $1/r$, where r is a radius, drawn in the direction of displacement of the surface—

$$(x^2+y^2+z^2-1)\left(\frac{x^2}{\mathrm{N}_1{}^2-1}+\frac{y^2}{\mathrm{N}_2{}^2-1}+\frac{z^2}{\mathrm{N}_3{}^2-1}\right)=x^2+y^2+z^2 \quad (59)$$

and the directions of vibration are the axes of a section of this surface by the wave.

These results are at variance with experiment, which requires that the wave surface should be that of Fresnel, and no reason is assigned in the paper for making a^2 rather than β^2 or γ^2 a function of the direction.

Circular polarisation and the rotation of the plane of polarisation [1] are also treated of by introducing into the equation for U the term $-2\mu\delta\cos\alpha\frac{d\mathrm{V}}{dt}$, and into the equation for V, $2\mu\delta\cos\alpha\frac{d\mathrm{U}}{dt}$, where δ depends on the strength of the magnetic force, and α is the angle between its direction and the axis of z.

From this it follows that the rotation is proportional to

$$\frac{a}{\lambda^2}+\frac{b}{\lambda^4}+ \quad . \quad . \quad . \quad .$$

and the results of calculation agree fairly well with Verdet's experiments.[2]

For the rotation of sugar terms of the same kind, but without the $\cos\alpha$, are introduced.

It has been shown long since, by Airy,[3] Neumann, and MacCullagh, that such terms in the equations would lead to results in fair agreement with experiment, and Lommel does not attempt any other justification of their existence than that the results they lead to are in agreement with experiment. Similar remarks apply to his paper on the properties of quartz,[4] in which the same terms are added to the differential equations already found for a crystalline media. The two waves travelling in any given direction inclined at an angle θ to the axis are elliptically polarised. The elliptic paths of the particles are similar; their ratio is given by—

$$\gamma=\frac{d_0\cos^2\theta}{b\sin^2\theta+\{b^2\sin^4\theta+d_0{}^2\cos^4\theta\}^{\frac{1}{2}}} \quad . \quad . \quad (60)$$

and the difference of phase between the two by

$$d^2=b^2\sin^4\theta+d_0{}^2\cos^4\theta \quad . \quad . \quad . \quad (61)$$

where b and d_0 are functions of the refractive indices and wave lengths. The axial rotation is given by—

$$\Omega=\mathrm{C}\frac{(\mathrm{N}^2-1)^2}{\mathrm{N}\lambda^2} \quad . \quad . \quad . \quad . \quad (62)$$

[1] Lommel, 'Theorie der Dehnung der Polarisationsebene,' *Wied. Ann.* t. xiv. p. 523.
[2] Verdet, *Ann. de Chim.* (3), t. 69, p. 471.
[3] Airy, *Phil. Mag.* June, 1846; Neumann, *Die magnetischen Dehnungen*, Halle, 1863; McCullagh, *Roy. Irish Trans.*
[4] Lommel, 'Theorie der elliptischen Doppelbrechung,' *Wied. Ann.* t. xv. p. 378.

These results are all in close agreement with experiment.

In another paper [1] this formula is carried to a higher degree of approximation, and reduces to $\Omega = \frac{a(N^2-1)^2}{\lambda^2}$. This agrees well with the measurements of Soret and Sarasin, between the wave lengths 7604 and 2143.

§ 2. Ketteler's contributions to the theory of double refraction have been very numerous. Most of the papers already mentioned,[2] contain something on the subject. The theory given in the first of the papers mentioned is in its fundamental principles in close accordance with that developed by Lord Rayleigh in 1871, though the equations given on p. 95, following Von Lang, as representing the motion in a crystalline elastic solid are incorrect. In it a distinction is drawn between the displacement normal to the ray, which leads, it is said, to equations of the form—

$$(m+m_x)\frac{d^2u}{dt^2}+\frac{dp}{dx}=a^2\nabla^2 u \quad . \quad . \quad . \quad (63)$$

and those in the wave front, for which the equations are—

$$(m+m_x)\left(\frac{d^2u}{dt^2}+\frac{dp}{dx}\right)=a^2\nabla^2 u \quad . \quad . \quad . \quad (64)$$

The arguments by which the second equation is deduced from the first are somewhat obscure; they are, however, further developed in a later paper.[3] The ray direction is defined as that in which the energy of the vibration is propagated, and the direction of vibration is normal to this.

The fundamental equations of this theory have already been given.[4] They are, in their final form,[5]

$$\left.\begin{aligned} m\frac{d^2u}{dt^2}-m'C_0\frac{d^2U}{dt^2}&=e\nabla^2u+\beta m'U \\ m'C_0\frac{d^2u}{dt^2}+m'\frac{d^2U}{dt^2}&=-\left(\kappa U+\gamma\frac{dU}{dt}\right) \end{aligned}\right\} \quad . \quad . \quad (65)$$

where the constants C_0, β, κ and γ may all be functions of the direction. It is shown in the paper ('Optische Controversen') now before us that the conditions of incompressibility require that C_0, κ and γ should be constant, so that the theory turns entirely on the variability with the direction of β, or rather of C', which is connected with C_0 by the equation—

$$C'=\beta\frac{r^2}{4\pi^2}-C_0 \quad . \quad . \quad . \quad . \quad . \quad (66)$$

This is fatal to the groundwork of the theory, for in its form in the 'Optische Controversen' it is assumed that C' and C_0 are unconnected. The paper 'Zur Dispersionstheorie' starts without the term in β, arriving at the equation $C'+C_0=0$, and then (p. 203) inserts the β ' in

[1] 'Lommel, 'Das Gesetz der Rotationsdispersion,' *Wied. Ann.* t. xx. p. 578.

[2] See p. 179; and also Ketteler, 'Zur Theorie der Doppelbrechung,' *Wied. Ann.* t. vii. p. 94; 'Theorie der absorbirenden Anisotropen-Mittel,' *Monatsber. der Königl. Akad. der Wiss. zu Berlin*, November 13, 1879.

[3] Ketteler, 'Optische Controversen II.' *Wied. Ann.* t. xviii. p. 631.

[4] See p. 228.

[5] Ketteler, 'Zur Dispersionstheorie des Lichtes,' *Wied. Ann.* t. xxi. p. 199.

order to explain experimental results.' Introducing the term C′, as defined above, the equations become—

$$\left.\begin{aligned} m\frac{d^2u}{dt^2} - m'C'_x\frac{d^2U}{dt^2} &= e\nabla^2 u \\ m'C_0\frac{d^2u}{dt^2} + m'\frac{d^2U}{dt^2} &= -\left(\kappa U + \gamma\frac{dU}{dt}\right) \end{aligned}\right\} \quad . \quad . \quad (67)$$

These equations will not lead to satisfactory results.

Circular[1] and elliptic polarisation are also treated of by Ketteler, and are explained on the supposition that terms of the form $-\left(\mathfrak{f}V + \mathfrak{g}\frac{dV}{dt}\right)$ come into the equation for U, and terms $+\left(\mathfrak{f}U + \mathfrak{g}\frac{dU}{dt}\right)$ into that for V. The rotation in a magnetic medium is given by $\Omega = \pi f\frac{(N^2-1)}{N\lambda^2}$, N being the refractive index, while the value of N in a crystal like quartz may be found from the formula—

$$\begin{aligned} N^2 - 1 = (N_1{}^2 - 1)(1 + \cos^2\theta) + (N_2{}^2 - 1)\sin^2\theta \pm [(N_1{}^2 - N_2{}^2)\sin^4\theta \\ + 4k^2\lambda^2\cos^2\theta(N_1{}^2 - 1)(N_1{}^2\cos^2\theta + N_2{}^2\sin^2\theta - 1)]^{\frac{1}{2}} \quad . \quad . \quad (68) \end{aligned}$$

N_1 and N_2 being the refractive indices at right angles to the axis, and k, a constant on which the rotatory power depends. For ordinary active media the law of the rotation is

$$\Omega = a + \frac{b}{\lambda^2} + \frac{c}{\lambda^4} +, \text{etc.} \quad . \quad . \quad . \quad (69)$$

It will be noticed that in the theories of both Lommel and Ketteler the rotatory terms are introduced into the equations of the matter particles, and affect the ether only indirectly through the values of u, v, and w.

§ 3. Voigt's work[2] embraces double refraction and circular polarisation. The existence of three principal axes is assumed, and for these the coefficients o and s in the values of f_1 and f_3* of equations (53) vanish. The values of f_5 and f_7 are written down with coefficients a_1, a_2, etc., and a_1', a_2', etc., respectively, and finally the equation of motion for u is obtained in the form—

$$\begin{aligned} (m + r_1)\frac{d^2u}{dt^2} = e\nabla^2 u + \frac{dp}{dx} - n_1 u + a_1\frac{d^2u}{dx^2} + b_{12}\frac{d^2u}{dy^2} + b_{13}\frac{d^2u}{dz^2} \\ + (c_3 + b_3)\frac{d^2v}{dxdy} + (c_2 + b_2)\frac{d^2}{dxdz} + \frac{d^2}{dt^2}\,[\text{similar terms with } a_1', \text{ etc.}] \quad (70) \end{aligned}$$

It will be seen that there are enough coefficients here to give any imaginable theory of double refraction.

Put $m + r_1 = m_1$, etc. Then the equations may be written

$$\left(m_1\frac{d^2}{dt^2} + n_1\right)u = A_1\frac{d^2u}{dx^2} + B_{12}\frac{d^2u}{dy^2} + B_{13}\frac{d^2u}{dz^2} + \frac{dP}{dx} \quad . \quad . \quad (71)$$

[1] Ketteler, 'Theorie der circularen und elliptischen polarisirenden Mittel,' *Wied. Ann.* t. xvi. p. 86.

[2] 'Theorie des Lichtes für vollkommen durchsichtige Medien,' *Wied. Ann.* t. xix. p. 873.

* See p. 231.

Where $A_1 = A_1 + A_1' \frac{d^2}{dt^2}$, A_1 and A_1' being functions of a, b, c, etc., and P is a linear function of p and the differential coefficients $\frac{du}{dx}$, etc.

The equations in this form may be compared with Green's, which differ from them only in the facts that his coefficients of d^2u/dt^2, d^2y/dt^2, and d^2z/dt^2 are the same, and his other coefficients are independent of the time. Voigt's equations, in fact, include both Green's and those given by Lord Rayleigh.

Let τ be the period of vibration, and denote $m_1 - n_1\tau^2$ by T_1, etc.; then it is shown that if we assume the relation $\frac{du}{dx} + \frac{dv}{dy} + \frac{dw}{dz} = 0$, in order to obtain Fresnel's wave surface at all the condition $T_1 = T_2 = T_3 = T$ is necessary.

These equations being satisfied, the other relations required to give Fresnel's construction on either assumption as to the connection between the plane of polarisation and the direction of vibration are those given by Green, with the addition that since in Voigt's coefficients the period is involved, and since Fresnel's construction holds for all wave lengths, each of Green's relations splits into two.

A difficulty as to the meaning of the constants leads Voigt to prefer Neumann and MacCullagh's theory as to the position of the plane of polarisation. To obtain Fresnel's original construction it is necessary to suppose B_{12} to be different from B_{21}, and this would imply that elastic reactions are brought into play by rotating an element of ether as a whole without dilatation; that, in the ordinary notation of elastic solids, T_{yz} is different from T_{zy}. If we treat this as out of the question, then B_{12} must be equal to B_{21}, and Fresnel's original construction for the plane of polarisation is impossible.

Circular polarisation is explained by the terms introduced by f_2, f_4, f_6, and f_8 of above,[1] but the terms to which f_4 and f_8 would give rise are omitted as not necessary to explain any known phenomena, and the equations in an isotropic medium become—

$$(m+r)\frac{d^2u}{dt^2} = (e+a)\frac{d^2u}{dz^2} + a'\frac{d^4u}{dz^2dt^2} - nu + p\frac{dv}{dt} + p\frac{p'd^3v}{dz^2dt} \quad . \quad (72)$$

etc.; the rotation produced by a thickness δ of the medium will be—

$$\Omega = \frac{\delta}{2\sqrt{(e+a)(m+r)}}\left(p - \frac{p'}{\tau^2\omega^2}\right)\left(1 + \frac{a'}{2(e+a)\tau^2}\right).$$

The same terms are then applied to a crystal, and the case of a uniaxial crystal such as quartz is worked out in full.

The equation to determine the velocity in a direction making an angle θ with the axis is found to be—

$$(\omega^2 - a^2)(\omega^2 - a^2\cos^2\theta - b^2\sin^2\theta) = \tau^2\left(p\omega^2 - \frac{p'^2}{\tau^2}\right) \quad . \quad (73)$$

a and b being the velocities at right angles to the axis.

This paper then gives a consistent account of the propagation of light in all known transparent bodies. We proceed to deal with the problem

[1] See p. 231.

of reflexion and refraction on this theory, and after that to make some general remarks on the whole.

Chapter III.—Reflexion and Refraction.

§ 1. Lommel, so far as I am aware, has not considered the problem of the reflexion and refraction of light on his theory. Ketteler, however, has discussed it in many of his papers.

In one of the earlier papers [1] the fundamental principles on which he intends to work are laid down. They are as follows:—

I. The conservation of energy.

II*a*. The continuity of the stress parallel to the surface of separation.

II*b*. The continuity of the component of the force on an element resolved normal to the surface.

III. The continuity of the displacement resolved along the surface.

The reasons given for II*b*. in place of the correct principle of the continuity of the stress normal to the surface are not very clearly stated.

No assumption, except such as is implied in I. and III. combined, is made as to the displacement normal to the surface.

The principles are then applied to the general problem, but in expressing them in symbols, except in the case of I., the motion of the matter is entirely neglected. Thus the stress considered in II. is only that arising from the action of the ether; the part which springs from the reaction of the matter is omitted from consideration. Again, in forming the equations connecting the amplitudes of the incident reflected and refracted rays, II*b*. is not employed.

Ketteler's work, then, in this paper is not really specially connected with his theory of the mutual reaction between the ether and matter. It is rather a modification of Fresnel and Green's work, for which there can be no justification assigned. The problem of metallic reflexion is discussed, and in a second part [2] of the same paper that of moving media. In the next paper on this subject [3] the correct principle of the continuity of the stress normal to the bounding surface is introduced in place of one of the other conditions, but it is supposed that the term involving the dilatation disappears in consequence of the incompressibility of the ether; in reality, as Green showed, the coefficient of that term is very large, and it must be retained to give correct results. Ketteler fails to see this, and hence concludes that the retention of Green's longitudinal wave is unnecessary. He then considers, as Green had done, the problem of total reflexion; and, through not taking into account the continuity of the displacement normal to the surface, appears to be able to do without the longitudinal waves. The motion of the matter particles does not come into consideration.

Another series of surface conditions are given in the next paper on the subject,[4] and the matter particles being treated merely as a sort of

[1] Ketteler, 'Beiträge zur einer endgültigen Feststellung der Schwingungsebene des polarisirten Lichtes,' *Wied. Ann.* t. i. p. 206.

[4] Ketteler, 'Ueber den Uebergang des Lichtes zwischen absorbirenden isotropen und anisotropen Mitteln und über die Mechanik der Schwingungen in denselben,' *Wied. Ann.* t. vii. p. 107.

ballast, their motions do not come into the surface conditions. While, finally,[1] Ketteler adopts the principle enunciated by Kirchhoff,[2] and already discussed above,[3] viz. that no work is done by the action of the stresses in the media on the bounding surface. In applying this principle he equates to zero, as Kirchhoff has done, the terms involving the dilatation; and this, as has been already shown, leads to MacCullagh's formulæ on his assumption as to the equality of the density in the two media, and to Fresnel's if the rigidity be assumed equal in the two. The theory is applied to metallic reflexion and total reflexion within crystals in another paper.[4] Thus, while Ketteler's first theory[5] was in reality Green's erroneously altered, this second theory is that given by Kirchhoff in the paper already quoted. Neither of them really seems to me to involve the distinctive features of Ketteler's theory of the propagation of light.

§ 2. Voigt's theory is contained in the paper already referred to.[6]

The conditions assumed are:—

I. The displacement of the parallel to the surface ether is continuous in the two media.

II. The displacement normal to the surface multiplied by the density is continuous.[7]

III. Kirchhoff's principle—viz. that the work done by the stresses on the interface of the two media vanishes.

In evaluating the expression for this work Voigt takes into account correctly the terms arising from the action of the matter on the ether. The displacements which come into the equations expressing the first two conditions are strictly displacements of the ether relatively to the matter, but since it is assumed that the motion of the matter particles is very small compared with that of the ether, the absolute displacements of the ether particles are introduced.

The results arrived at, however, are hardly satisfactory. In the first place, in evaluating the expression for the work done on the surface, the term involving the dilatation is omitted. Voigt has taken it into account in his equations of motion; his reason for omitting it here is not given. He thus avoids the question of the so-called longitudinal vibrations.

He then considers the case of vibrations at right angles to the plane of incidence, and arrives at the formulæ—

$$\left.\begin{aligned} &E_s + R_s = D_s \\ &(m_1 + r_1 - n_1\tau^2)\,(E_s - R_s)\sin\phi_1\cos\phi_1 \\ &\qquad = (m_2 + r_2 - n_2\tau^2)\,D_s\sin\phi_2\cos\phi_2 \end{aligned}\right\} \quad . \quad . \quad (74)$$

E, R, and D being the amplitudes of the incident reflected and refracted waves.

[1] 'Ketteler, 'Optische Controversen II.' *Wied. Ann.* t. xviii. p. 632.
[2] Kirchhoff, *Abhandl. der Berl. Akad.* 1876, p. 57.
[3] See p. 193.
[4] Ketteler, 'Ueber Probleme welche die Neumann'sche Reflexionstheorie nicht lösen zu können scheint,' *Wied. Ann.* t. xxii. p. 204.
[5] See p. 162.
[6] Voigt, 'Theorie des Lichtes für vollkommen durchsichtige Medien,' *Wied. Ann.* t. xix. p. 873. See also Voigt, 'Ueber die Grundgleichungen der optischen Theorie des Herrn E. Ketteler,' *Wied. Ann.* t. xix. p. 691, especially p. 696 *seq.*
[7] See p. 186; also Cornu, *Ann. de Chim.* (4), t. xi. p. 283.

These become MacCullagh's and Neumann's formulæ on the assumption that

$$\left.\begin{aligned} m_1 + r_1 &= m_2 + r_2 \\ n_1 &= n_2 \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (75)$$

They become Fresnel's if

$$\left.\begin{aligned} e_1 + a_1 &= e_2 + a_2 \\ a'_1 &= a'_2 \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (76)$$

for these equations lead—remembering the value of the velocity—to the condition—

$$\frac{m_1 + r_1 - n_1 \tau^2}{m_2 + r_2 - n_2 \tau^2} = \frac{\sin^2 \phi_2}{\sin^2 \phi_1}.$$

For the vibrations in the plane of incidence the results of the first and second principles are inconsistent with that of the third. For the first and second give

$$\left.\begin{aligned} (\mathrm{E}_p + \mathrm{R}_p) \cos\phi_1 &= \mathrm{D}_p \cos\phi_2 \\ m_1(\mathrm{E}_p - \mathrm{R}_p) \sin\phi_1 &= m_2 \mathrm{D}_p \sin\phi_2 \end{aligned}\right\} \quad . \quad . \quad . \quad (77)$$

while the first and third give, instead of this second equation,

$$(m_1 + r_1 - n_1\tau^2)\ (\mathrm{E}_p - \mathrm{R}_p)\ \sin\phi_1 = (m_2 + r_2 - n_2\tau^2)\ \mathrm{D}_p\ \sin\phi_2\ . \quad (78)$$

They become consistent if we assume $m_1 = m_2$, and, adopting Neumann's hypothesis,

$$r_1 = r_2, \quad n_1 = n_2,$$

or, adopting Fresnel's,

$$e_1 + a_1 = e_2 + a_2, \quad a'_1 = a'_2.$$

In another paper[1] it is shown that Kirchhoff's principle, when applied to circularly polarising media, leads to an impossible result, and the principle is modified by the supposition that the work done is a function of the time only, and not zero.

The theory of ordinary absorbing media is developed[2] from the supposition that terms involving a loss of energy may come in through the mutual reaction of the ether and matter, and it is shown that these would lead to terms of the form $-b\dfrac{du}{dt} + c\nabla^2\dfrac{du}{dt}$ in the equation for u, which merely becomes, for waves travelling parallel to z,

$$\mathrm{M}_1 \frac{d^2u}{dt^2} = \mathrm{A}_1 \frac{d^2u}{dz^2} - b\frac{du}{dt} + c\frac{d^3u}{dz^2dt} \quad . \quad . \quad . \quad (79)$$

where

$$\left.\begin{aligned} \mathrm{M}_1 &= m_1 + r_1 - n_1\tau^2 \\ \mathrm{A}_1 &= e_1 + a_1 - \frac{a'_1}{\tau^2} \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (80)$$

In considering the problem of reflexion in this case, Voigt assumes that the plane xy being the face of incidence, $\mathrm{M}w$ is continuous. The

[1] Voigt, 'Das G. Kirchhoff'sche Princip und die Theorie der Reflexion und Brechung an der Grenze circular-polarisender Medien,' *Wied. Ann.* t. xx. p. 522.

[2] Voigt, 'Theorie der absorbirenden isotropen Medien,' *Wied. Ann.* t. xxiii. p. 104.

principle laid down in the former paper[1] would require that this should be mw, not Mw, as he points out, remarking that the equation given is only true under certain restrictions, and, in fact, he shows that for vibrations in the plane of incidence the continuity of Mw is inconsistent with the energy equation, at least unless $b=0$. The energy equation gives—

$$M_1 w_1 = M_2 w_2 - b_2 \tau \frac{dw_2}{dt} \Big\} \quad . \quad . \quad . \quad (81)$$

and this form is assumed for the rest of the work.

Expressions are then found for the difference of phase between the reflected, refracted, and incident beams, and for their relative intensities, and these are compared with theory on the assumption that the constant b vanishes, and that $M_1 = M_2$. The results of the comparison are satisfactory; but this, however, can hardly be said for the principles from which they are deduced, while the difficulties we have already alluded to as to the negative value for the real part of the square of the refractive index remain in their full force.

Chapter IV.—Theory of Sir William Thomson. General Considerations.

§ 1. The lectures of Sir William Thomson delivered last year at Baltimore have developed a new interest in the theories now under consideration. After discussing at some length the elastic solid theory and throwing much light on it, and on the meaning of the twenty-one coefficients of Green's theory, he points out its unfitness to explain the phenomena, and then proceeds to work out the consequences of a special form of reaction between the ether and matter; this he illustrates in his own inimitable manner by his mechanical model of the ether within a transparent body. This mechanical model consists of a number of concentric hollow spheres. Each sphere is connected with the one within it by zigzag springs, and in the centre there is a solid mass connected also by springs with the shell next to it. The dimensions of these shells, which represent the matter molecules, are supposed to be small compared with the wave length. The interior molecule will have a number of periods of vibration depending on the number and nature of the spring connections, on its own mass, and on the masses of the shells. The springs are supposed to be massless. The shell molecules are distributed through the ether in very large numbers, and the outermost shell is connected with the ether.

It is further supposed that the forces arising from the springs are proportional to the relative displacements of the centres of the shells, and that the ether acts on the first shell with a force proportional to the relative displacement of that shell and the ether surrounding it, so that, if ξ be the ether displacement, x_1, x_2 those of the shells, $m_1/4\pi^2$, $m_2/4\pi^2$, etc. their masses, the equations of motion are,

$$\left.\begin{aligned} \frac{m_1}{4\pi^2}\frac{d^2x_1}{dt^2} &= C_1(\xi - x_1) - C_2(x_1 - x_2) \\ \frac{m_2}{4\pi^2}\frac{d^2x_2}{dt^2} &= C_2(x_1 - x_2) - C_3(x_2 - x_3) \end{aligned}\right\} \quad . \quad . \quad (82)$$

[1] Voigt, *Wied. Ann.* t. xix. p. 900. See above, p. 239.

etc. If we suppose the whole motion to be harmonic and of period τ, then the equations become

$$-\frac{m_1}{\tau^2}x_1 = C_1(\xi - x_1) - C_2(x_1 - x_2) \quad . \quad . \quad . \quad (83)$$

etc., from which the motion of the various shells can be determined. The system will represent Helmholtz's theory if we suppose the viscous terms in his expression to vanish, and consider only a single shell. The solution in the general case is carried further by putting

$$\left.\begin{aligned} a_i &= \frac{m_i}{\tau^2} - C_i - C_{i+1} \\ \text{and} \qquad u_i &= -\frac{C_i x_{i-1}}{x_i} \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (84)$$

The equations may then be written—

$$\left.\begin{aligned} u_1 &= a_1 - \frac{C_2{}^2}{u_2} \\ u_2 &= a_2 - \frac{C_3{}^2}{u_3} \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad . \quad (85)$$

etc., whence we find u_1 as a continued fraction.

By differentiating these expressions with reference to τ^{-2}, and writing δ for $\frac{d}{d\tau^{-2}}$, we find—

$$\delta u_i = m_i + \left(\frac{C_{i+1}}{u_{i+1}}\right) m_{i+1} + \left(\frac{C_{i+1}C_{i+2}}{u_{i+1}u_{i+2}}\right)^2 m_{i+2} +, \text{ etc.} \quad . \quad . \quad (86)$$

Hence

$$\frac{du_i}{d\tau} = -\frac{2}{\tau^3}\frac{1}{x_i^2}\left\{m_i x_i^2 + m_{i+1}x^2_{i+1} + \quad . \quad . \quad . \quad . \right\} \quad . \quad . \quad (87)$$

Thus u decreases as τ increases, and if we start from τ, a small quantity, the u's are all large and positive; hence alternate shells are moving in opposite directions, and the motion of consecutive shells rapidly decreases.

As τ increases the u's decrease, and after a time one will become negative, passing through zero—it can be shown that u_1 is the first one thus to become negative. This gives the first critical case in the solution, for then x_1 is infinitely great compared with ξ, and the solution fails.

This equation can be put into the following more convenient form—

$$\frac{-x_1}{C_1\xi} = \frac{\tau^2}{m_1}\left\{\frac{\kappa_1{}^2 R_1}{\kappa_1{}^2 - \tau^2} + \frac{\kappa_2{}^2 R_2}{\kappa_2{}^2 - \tau^2} + . \quad . \quad . \quad . \right\} \quad . \quad . \quad (88)$$

where κ_1, κ_2, etc., are the critical values of τ, and R_1, R_2, etc., represent the ratio of the energy of the several shells to the whole energy of the system.

To apply this to the motion of the ether in a transparent body, let $m_1/4\pi^2$, etc., represent the whole mass contained within shell No. 1 per unit vol., let $\rho/4\pi^2$ be the density, and $e/4\pi^2$ the rigidity of the ether, and suppose the first shell, of mass m_1, to be connected by a spring to a massless

spherical lining, which is in rigid connection with the ether outside. Then the equation of motion is—

$$\rho \frac{d^2\xi}{dt^2} = e\frac{d^2\xi}{dx^2} + 4\pi^2 C_1 (x_1 - \xi) \quad . \quad . \quad . \quad (89)$$

Let the solution of this represent a train of waves of period τ and length λ, and let V be the wave velocity for the medium. Then

$$\frac{1}{V^2} = \frac{\tau^2}{\lambda^2} = \frac{1}{e}\left\{\rho - C_1\tau^2\left(1 - \frac{x_1}{\xi}\right)\right\}$$

$$= \frac{1}{e}\left[\rho - C_1\tau^2\left\{1 + \frac{C_1\tau^2}{m_1}\left(\frac{{}_1{}^2R_1}{\kappa_1{}^2 - \tau} + \frac{\kappa_2{}^2R_2}{\kappa_2{}^2 - \tau^2} + \ldots\right)\right\}\right] . \quad (90)$$

and if μ be the refractive index, since the velocity in free space is $\sqrt{e/\rho}$ we have, if we put $C_1\kappa_1{}^2R_1 = q_1 m_1$, etc.

$$\mu^2 = 1 + \frac{C_1}{\rho}\left\{q_1\kappa_1{}^2 - (1 - q_1)\tau^2\right.$$

$$\left. + q_1\kappa_1{}^2\left(\frac{\kappa_1{}^2}{\tau^2} + \frac{\kappa_1{}^4}{\tau^4} + \ldots\right) - \text{terms in } q_2, q_3\right\} \quad . \quad . \quad (91)$$

It follows from this that, q_1 must be very little less than unity if the formula, neglecting the terms in q_2, etc., is to apply to a transparent substance such as rock salt, which gives a value for μ between 1 and 2 for a range of the spectrum from the visible light to the longest waves emitted by a Leslie cube. The formula, we note, is the same in form as that given by Ketteler and Briot (see above, page 181), and Ketteler has shown that in some fairly transparent substances the coefficient $1 - q_1$ is appreciable. q_1 is essentially less than unity, so that the term in τ^2 comes in with a negative coefficient. The formula, then, will explain ordinary dispersion fairly if we put q_2, q_3, etc., all zero and take τ greater than κ_1.

The critical cases are then discussed from the form

$$\mu^2 = 1 + \frac{C_1\tau^2}{\rho}\left(-1 + \frac{q_1\tau^2}{\tau^2 - \kappa_1{}^2} - \frac{q_2\tau^2}{\kappa_2{}^2 - \tau^2} - \ldots\right\} \quad . \quad (92)$$

In this, τ is greater than κ_1 and less than κ_2 for ordinary refraction. As τ decreases down to κ_1, μ^2 passes through the value infinity and then becomes negative, we have greater and greater refraction, and then the waves cease to be transmitted and absorption takes place.

And here we are met with the question—What becomes of the energy thus absorbed? According to our equation the ratio x_1/ξ becomes infinite, and the solution as it stands fails to meet this difficulty. Helmholtz introduced the term $-\gamma^2 dU/dt$ into the motion of the first shell, and this, representing as it does a viscous consumption of energy by the matter molecules, is objected to by Sir Wm. Thomson. Helmholtz's solution given on p. 221 becomes identical with that at present under discussion if we put $\gamma = 0$; it is to meet this case in which $\tau = \kappa_1$ that the term in γ^2 is introduced, for if k represent the co-efficient of absorption on Helmholtz's theory, and we suppose γ to be small, then, with Thomson's notation,

$$k = K\frac{\gamma^2\tau^4}{(\tau^2 - \kappa_1{}^2)^2}$$

very approximately, K being a constant, and k may be very small except when τ is nearly equal to κ_1.

In order to account for the extreme transparency of a substance such as water, we must suppose k to be so exceedingly small that Sir William prefers to consider it as zero, and says: 'I believe that the first effect when light begins, of period exactly equal to κ_1, is that each sequence of waves throws in some energy into the molecule. That goes on until somehow or other the molecule gets uneasy. It takes in (owing to its great density relative to the ether) an enormous quantity of energy before it gets particularly uneasy. It then moves about, and begins to collide with its neighbours, perhaps, and will therefore give you heat in the gas if it be a gaseous molecule. It goes on colliding with other molecules, and in that way imparting its energy to them. This energy is carried away (as heat) by convection, perhaps. Each molecule set to vibrating in that way becomes a source of light, and we may thus explain the radiation of heat from the molecule after it has been got into it by sequences of waves of light.'

Helmholtz's equations are, of course, the more general, and apply to an absorption band as well as to the part of the spectrum for which the medium is transparent. It would seem that the term $-\gamma^2 d\text{U}/dt$ may rightly represent just the effect of that loss of energy in the form of heat due to the irregular collisions of which Sir William speaks, an effect which is only appreciable in the result when, owing to the coincidence of the periods, U tends to become large compared with u, or, in Thomson's notation, x_1 large compared with ξ, and in this case x_1 will not become infinite, for the amplitude will be multiplied by the factor e^{-kz}, and k being large, the limit of the product comes into consideration.

Such a system of ether with attached matter molecules is thus shown to account for the phenomena of dispersion. A serious difficulty, however, is encountered when we reach the problem of double refraction.

§ 2. For we may suppose, in order to account for it, that C_1 is a function of the direction, and that for two principal directions it has the values C_1 and C_1', while C_2 is a constant independent of the direction.

Then, with only one enclosed mass,

$$\mu^2 = 1 + \frac{C_1\tau^2}{\rho}\,\frac{\left(\frac{m_1}{\tau^2} - C_2\right)}{C_1 + C_2 - \frac{m_1}{\tau^2}}; \qquad \qquad (93)$$

and to give a dispersion formula resembling Cauchy's we must have m_1/τ^2 considerable compared with C_2, and C_1 large compared with either.

Hence, if μ' be a second principal index,

$$\mu'^2 = 1 + \frac{C_1'\tau^2}{\rho}\,\frac{\left(\frac{m_2}{\tau^2} - C_2\right)}{C_1' + C_2 - \frac{m_1}{\tau^2}},$$

and therefore

$$\mu^2 - \mu'^2 = -\frac{C_1 - C_1'}{\rho}\,\frac{\tau^2\left(C_2 - \frac{m_1}{\tau^2}\right)^2}{\left(C_1 + C_2 - \frac{m_1}{\tau^2}\right)\left(C_1' + C_2 - \frac{m_1}{\tau^2}\right)}. \qquad (94)$$

which, remembering the relative magnitudes of the quantities, and writing D and D′ for the approximate values of the denominators, becomes

$$\mu^2 - \mu'^2 = -\frac{C_1 - C_1'}{\rho DD'}\left(\frac{m_1}{\tau}\right)^2$$

so that the difference between the squares of the refractive indices will be inversely proportional to the squares of the wave length, and this is quite contrary to experiment. The question as to whether the theory here suggested would lead to Fresnel's construction is not considered.

In a later lecture Sir William returns again to the question of what becomes of the energy absorbed by the molecules, and of the nature of the ether. As to the latter he adopts Stokes's view, that the medium may be perfectly elastic for the small disturbances of a light-wave, executed, as they are, in the twenty-million-millionth of a second, and yet be a perfect fluid in respect of forces which act, as may be supposed in the kinetic theory of gases, for the one-millionth of a second. Now, the numerical calculations of Professor Morley, undertaken at Sir William's suggestion, show that the energy given to a system such as described tends to become absorbed by the vibrations of lower modes, so that the original energy appears as vibrations in which the period may be the millionth of a second instead of, perhaps, the twenty-million-millionth, and this energy shows itself in the motions which we deal with in the kinetic theory of gases, rapid it may be in themselves, but slow compared with the light-vibrations.

§ 3. Metallic reflexion and the quasi-metallic reflexion of such substances as give anomalous dispersion are dealt with, and it is shown that the phenomena are such as would be produced by making μ^2, a negative quantity, and this is given by values of τ a little below the critical period.

Thus the molecular explanation of the great reflecting power of silver is that the highest mode of vibration of the molecules with which silver loads the ether is graver than the mode of the gravest light or radiant heat which has ever been reflected from silver; and if, again, for certain modes μ^2 is not negative, but less than unity, it shows that, conformably with the experiments of Quincke on gold leaves, we should expect light to travel through the medium faster than through air. This forms a marked and most important distinction between this theory and others which have been given to explain metallic reflexion. For the other theories the metallic effects arise from the importance of the viscous terms of the form $-\gamma du/dt$.

In an appendix Sir William works out the problem of reflexion and refraction, following Green and Lord Rayleigh so far as ordinary transparent media are concerned. He then transforms Green's formulæ for vibrations in the plane of incidence to the case in which μ^2 is a real negative quantity, and arrives at formulæ expressing, on a strict elastic solid theory, the intensity and change of phase in a wave reflected from metal.

According to this solution we have, if $\nu^2 = -\mu^2$ so that ν^2 is positive, the values of Φ and Ψ given by—

$$\left.\begin{aligned}
\Psi &= -\nu^2 \cos(ax+by+\omega t) + \tan\theta \frac{(\nu^2+1)^2}{\nu^2-1} \sin(ax+by+\omega t) \\
\Psi_1 &= -\nu^2 \cos(ax+by+\omega t) - \tan\theta \frac{(\nu^2+1)^2}{\nu^2-1} \sin(+ax+by+\omega t) \\
\Phi &= \frac{\nu^2(\nu^2+1)}{\nu^2-1} \epsilon^{-bx} \sin(by+\omega t) \\
\Psi' &= 2\epsilon^{bx} \cos(by+\omega t) \\
\Phi' &= -\frac{(\nu^2+1)}{\nu^2-1} \epsilon^{bx} \sin(by+\omega t)
\end{aligned}\right\} . \quad (95)$$

These are simplified if we put—

$$\left.\begin{aligned} h^2 &= \{(\nu^2+1)\,b^2+\nu^2a^2\}\left[\frac{h}{a}+\tan\theta\,\frac{(\nu^2+1)^2}{\nu^2-1}\right]\nu^2=\tan f \\ \mathrm{S} &= \nu^2\sec f \end{aligned}\right\} \quad . \quad (96)$$

and the displacements in the transparent medium are then, for the incident wave,

$$-\frac{2\pi}{\lambda}\,\mathrm{S}\,\sin\,(ax+by+\omega t+f),$$

and for the reflected,

$$\frac{2\pi}{\lambda}\,\mathrm{S}\sin\,(-ax+by+\omega t-f).$$

In this case the rigidities in the two media are supposed to be equal. Sir William has also worked out the problem in the case in which the rigidities are not equal, in the hopes that by this assumption combined with variations in the density—or rather effective density—the variations from Green's formulæ in the case of light polarised at right angles to the plane of incidence may be accounted for. He finds, however, that any difference of rigidity which might, combined with a difference of density, be sufficient to reconcile Green's theory with experiment would cause the proportion of light reflected at normal incidence to be greater than $\{(\mu-1)/(\mu+1)\}^2$, and this value, given by Green's theory, agrees closely with Rood's experiments. We are thus driven back to Lord Rayleigh's case of equal rigidities in the two media. For metals, then, we are to have the rigidities equal, and the value of μ^2 decreasing from $-\infty$ when $\tau=\kappa_1$ to zero when $\tau=\kappa_1/\mathrm{N}$, N being some large numerical quantity, and then again augmenting from zero to unity as τ decreases from κ_1/N to 0.

The dynamics give no foundation to a theory such as Cauchy's, in which μ^2 is a complex quantity. For light polarised in the plane of incidence we have, if n and n' be the rigidities, and

$$\left.\begin{aligned} r &= n'/n, \\ \text{and} \qquad \tan e &= r\{\nu^2\sec^2\theta+\tan^2\theta\}^{\frac{1}{2}} \end{aligned}\right\} \quad . \quad . \quad . \quad (97)$$

$$\left.\begin{aligned} \mathrm{R} &= \tfrac{1}{2}\{1+r^2(\nu^2\sec^2\theta+\tan^2\theta)\} \\ \zeta &= \mathrm{R}\cos\,(ax+by+\omega t-e) \\ \zeta &= \mathrm{R}\cos\,(-ax+by+\omega t+e) \end{aligned}\right\} \quad . \quad . \quad . \quad (98)$$

for the incident and reflected wave; and for the refracted wave,

$$\zeta=\varepsilon^{\frac{2\pi n}{\lambda}x\,(\nu^2+\sin^2\theta)^{\frac{1}{2}}}\cos\,(by+\omega t) \quad . \quad . \quad . \quad (99)$$

According to these formulæ the reflexion is total from a metal surface at all angles of incidence. Sir John Conroy has recently shown that the loss is exceedingly small. If light be polarised in any plane, then the vibration in the plane of incidence is retarded relatively to that at right angles to that plane by the amount $2f+2e-\pi$. If we suppose ν and $r\nu$ to be both very large numerics, this retardation becomes—

$$2\left\{\tan^{-1}\left(\frac{\sec\theta}{r\nu}+\ \tan\ \theta\right)-\tan^{-1}\left(\frac{\cos\theta}{r\nu}\right)\right\},$$

and from the observations which have been made on the value of the principal incidence, for which the retardation is $\frac{1}{2}\pi$, we can find a value for $r\nu$. For silver Sir J. Conroy's observations give $(r\nu)^{-1} = 3{\cdot}65$.

And here we are met with a great difficulty. Experiments show that there is very little chromatic effect about metallic reflexion. Thus, since the value of the principal incidence depends mainly on $r\nu$, this quantity must be independent of the period. Now $\nu^2 + 1$ is approximately proportional to τ^2 when τ is small compared with κ_1, and so this result requires that r, which is proportional to the effective rigidity, should also vary in a certain definite manner, and it is difficult to see how the theory is to give this.

The theory is then applied to the case of a thin metal plate, and leads to the fact that the phase of both components is accelerated by the transmission. The accelerations for the two cases are given by—

$$\delta \cos\theta + \left(\frac{e}{\pi} - \frac{1}{4}\right)\lambda, \text{ vibrations normal to the plane of incidence,}$$

$$\delta \cos\theta + \left(\frac{1}{4} - \frac{f}{\pi}\right)\lambda, \text{ vibrations in the plane of incidence,}$$

when δ is the thickness of the plate, and e and f are found in the same manner as above.

This acceleration was discovered by Quincke, but the details of his results do not agree well with the formulæ. The formulæ are consistent with Kerr's discovery of the rotation of the plane of polarisation by reflexion from an iron plate when magnetised, but not with Kundt's result that transmission through a thin plate of iron in a magnetic field produces a very large rotation of the plane of polarisation.

In a final appendix an account is given of a gyrostatic molecule, the properties of which would give to the medium the heliacal effects seen in sugar and other active solutions. The molecule consists of a spherical shell in which are imbedded two gyrostats having a common axis, which initially is a diameter of the shell. One end of each axis is connected with the shell by a ball-and-socket joint, while the second extremities of each are connected together at the centre of the shell by a second ball-and-socket joint.

§ 4. Having thus given an account of the various theories proposed based in some way on the mutual reaction between the ether and matter, it remains to compare and contrast them.

The theories of Boussinesq and Voigt have much in common, and neither of the two as they stand applies to the case of bodies showing strong absorption, for the matter motion is entirely neglected. The theories of Sellmeyer, Helmholtz, and Thomson come under one head in that they all make the mutual reaction to depend on the relative displacement of the matter and ether.

Lommel's theory seems to me untenable: in its original form it contradicts the third law of motion, and if modified so as to be consistent with that, it leads to impossible laws for the relation between refraction and absorption; besides this, his theory of double refraction does not lead to Fresnel's wave surface, and there seems no reason why the coefficient a^2, which occurs only in the equation of motion of the matter, should be the one to be treated as a function of the direction. The laws of circular polarisation and of the double refraction in quartz, to which the theory leads, and which seem to agree with experiment, may be obtained

with sufficient approximation to fit the experiments from other theories; and, indeed, the fact that the wave surface in quartz does not become a sphere and a spheroid when the heliacal terms are neglected is fatal.

With regard to Ketteler's theory in the form finally given to it by its author,[1] it seems to me to have no possible mechanical basis. With the interpretation which he gives of the constants involved, his equations appear to contradict Newton's third law as effectually as do Lommel's, while, so far as the problem of reflexion and refraction is concerned, I cannot recognise the validity of Kirchhoff's principle as it is applied by Ketteler. At the same time I think that the suggestion of Ketteler—to which, however, he himself takes objection—already mentioned, leads to results which, so far as dispersion is concerned, agree closely with experiment.

We may with advantage compare the dispersion formula which it gives with that which comes from the theories of Helmholtz and Thomson. If we neglect the terms depending on viscous action, we have, according to Helmholtz, for μ, the refractive index,

$$\mu^2 = 1 - \frac{B\lambda^2}{\rho\lambda_1{}^2} + \Sigma\frac{B^2}{\rho m_1}\left\{\frac{\dfrac{\lambda^4}{\lambda_1{}^4}}{\dfrac{\lambda^2}{\lambda_0{}^2} - 1}\right\} \quad . \quad . \quad . \quad (100)$$

while, according to the modified form of Ketteler,

$$\mu^2 = \mu^2_\infty \left[1 + \Sigma\left\{\frac{D}{\dfrac{\lambda^2}{\lambda_0{}^2} - 1}\right\}\right] \quad . \quad . \quad . \quad (101)$$

Ketteler's equations come from Thomson's or Helmholtz's by writing for C_1 the quantity $-4\pi^2 C_1/\tau^2$, or for β^2 in Helmholtz's notation $-n^2\beta^2$. We may write Ketteler's equation in the form of a series thus—

$$\mu^2 = \mu^2_\infty \left[1 + \Sigma D\frac{\lambda_0{}^2}{\lambda^2}\left(1 - \frac{\lambda_0{}^2}{\lambda^2}\right)^{-1}\right]$$

$$= \mu^2_\infty \left[1 + \Sigma D\left\{\frac{\lambda_0{}^2}{\lambda^2} + \frac{\lambda_0{}^4}{\lambda^4} + \quad . \quad . \quad . \quad . \right\}\right] \quad . \quad (102)$$

two terms of which will give us Cauchy's series with three constants.

This modification leads also to an escape from one of the difficulties suggested by Sir William as to the explanation of double refraction.

For his general expression for μ^2 will become, if we write for C_1 the value $-4\pi^2 C_1/\tau^2$,

$$\mu^2 = 1 + \frac{4\pi^2 C_1}{\rho}\left\{1 - \frac{4\pi^2 C_1}{m_1}\left(\frac{\kappa_1{}^2 R_1}{\kappa_1{}^2 - \tau^2} + \quad . \quad . \quad . \quad . \right)\right\} \quad . \quad (103)$$

If we neglect for a moment the terms on which the dispersion depends, as being small compared with the term $4\pi^2 C_1/\rho$, which gives rise in the first instance to refraction, we get that

$$\mu^2 - \mu'^2 = \frac{4\pi^2(C_1 - C_1')}{\rho} \quad . \quad . \quad . \quad (104)$$

and there will be double refraction independently of the period.

[1] Ketteler, 'Zur Dispersionstheorie des Lichtes,' *Wied. Ann.* t. xxi. p. 199.

It is another question, and one which we shall discuss shortly, whether the double refraction thus produced will give rise to Fresnel's wave surface.

There seem, then, to be reasons why we should expect terms such as Ketteler has suggested in our equations—terms which will make the mutual reaction of the ether and the first matter shell depend rather upon their relative accelerations than upon their relative displacements. It is not so easy to suggest a mechanical connection between the ether and matter which would give rise to this force, but at the same time there is, I think, no mechanical reason to be urged against it.

Voigt's theory of wave propagation is in one way more comprehensive than those we have considered, while in another it is less so. It is more comprehensive in that it includes both sets of terms with some others in the expression for the mutual reaction; it is less so in that it treats the ratio U/u as a small quantity which may be neglected. This same remark applies to Boussinesq, whose work in one sense is more general that Voigt's, in that he considers the effect of the attached molecules on the condensational or pressural wave.

The presence of these molecules has been shown in Boussinesq's paper to alter the effective compressibility of the medium as well as its density and its rigidity. In the ether we assume that the compressibility is small compared with the rigidity, so small that the ratio of the two may be neglected, and this must still be the case, even when the ether is loaded. But when dealing with the problem of reflexion we are concerned with the refractive index of the medium for the condensational wave. This will depend on the ratio of the two effective compressibilities, as well as on that of the two effective densities, and though either of the two compressibilities may vanish when compared with the rigidities, in considering their ratio it becomes necessary to take into account any change due to the loading of the ether.

It may not be unreasonable, then, to suppose that the effective density of the ether for the condensational wave is different from the effective density for the transverse wave. This supposition would account easily for the variation from Green's formula observed when plane polarised light polarised at right angles to the plane of incidence is reflected from a transparent surface, in that it would allow us to introduce the second constant μ_0, as suggested by Haughton and Lord Rayleigh.[1]

Let us now consider Voigt's theory. With regard to the problem of reflexion his surface conditions appear to be unsound. The ether is the continuous medium, and the surface conditions must apply to it simply. The conditions of continuity demand that the actual displacements of the ether and the actual stresses over the interface, arising, of course, in part from the action of the matter, should be the same in the two media. The validity of Kirchhoff's principle has already been considered, and it has been shown that it does not lead to results in accordance with experiment, for it does not give the change of phase which in some cases accompanies reflexion.

But, while this is so, Voigt's theory shows us that the effects of the attached molecules may show themselves either in the rigidity or the density of the ether. Now, the work of Lord Rayleigh and Lorenz has proved that the effects of reflexion are due mainly, if not entirely, to differences of effective density; and so we must look to the terms in

[1] See p. 192.

Voigt's theory which affect the density as the most important. These terms are

$$-\left(r\frac{d^2}{dt^2}+n\right)(u-\text{U}).$$

The other terms,

$$\left(a\frac{d^2}{dz^2}+a'\frac{d^4}{dz^2dt^2}\right)(u-\text{U}),$$

show themselves as a variation of the effective rigidity. In order to obtain a consistent theory of reflexion we must treat these as of secondary importance compared with the first terms. Now, this is inconsistent with both theories of double refraction as advanced by Voigt, for the first condition for either is that r and n must be independent of the direction. It would seem from this that they should be the same in all media. Boussinesq adopts the opposite view. He makes his double refraction depend on the terms which correspond to r and n, and neglects the variations of the others with the direction. If we do this—and we seem to be forced into it by the further requirements of our theory—the fundamental equations in a crystal become those given by Lord Rayleigh. These, we have seen, if we assume the strict transversality of the vibrations, do not lead to Fresnel's wave surface. On the other hand, if we suppose that the vibrations in a crystal are at right angles to the ray, not to the wave normal, the result agrees with all the consequences of experiment, for we obtain Fresnel's surface as the wave surface, but we are left in a difficulty as to the normal wave.

With regard to metallic reflexion, the theory as given by Sir W. Thomson explains completely the difficulty raised by Lord Rayleigh as to a negative value for μ^2. It does not, however, enable us to decide how much of the effect is due to the fact that the highest possible free period of the ether in the metallic medium is below that of the incident light, and how much is due to opacity arising from terms such as du/dt, as supposed by Lord Rayleigh. The correct equations to which such a theory would give rise are yet unsolved, but the principles required by the solution are well known.

It seems, then, that this theory promises to afford us the solution of the difficulties which still surround theoretical optics, and to account at once for the phenomena of reflexion and refraction, dispersion and double refraction. Of course, in all cases of transparency the matter motion is infinitesimally small compared with that of the ether. The ether is to be looked upon as moving through a sort of network of fixed matter particles. Terms depending on the reaction between the ether and these fixed portions of matter will be introduced into the equations, and these terms will be expressible as functions of u, v, w and their differential coefficients. The matter particles will not move appreciably, and their movement is not necessary for the explanation of refraction and ordinary dispersion; for on Ketteler's modified theory we have, if we omit the viscous terms,

$$\mu^2=1+\frac{\beta^2}{m}+\frac{\beta^4n^2}{m\mu\,(\nu^2-n^2)},$$

and the ratio of the amplitudes is

$$-\frac{\beta^2n^2}{\mu(\nu^2-n^2)}.$$

From the value of μ^2 we see that β^2 must be comparable with m, the density of the ether, so that, except when $n^2/(\nu^2-n^2)$ is a large quantity, the ratio of the amplitudes will be inversely as the densities, for β^2/μ will be comparable with m/μ. When, however, $n^2/(\nu^2-n^2)$ is large, the matter motion becomes appreciable, and the phenomena of anomalous dispersion arise.

PART IV.

THE ELECTRO-MAGNETIC THEORY.

Chapter I.—MAXWELL'S THEORY.

§ 1. There remains now for consideration Maxwell's electro-magnetic theory. The fundamental equations of this theory are purely electrical, and are established on electrical principles. According to Maxwell, when electromotive force acts on a dielectric medium the change of condition known as electric displacement is produced. The two are connected by the equations—

$$\mathrm{P}=\frac{4\pi}{\mathrm{K}}f, \text{ etc.} \qquad (1)$$

P, Q, R being the components of the E.M.F. and f, g, h of the displacement. K is the inductive capacity. In a crystal the equation holds only for the principal axes, and along these K has three different values.

The rate of variation of the displacement given by $\dot{f}$, $\dot{g}$, $\dot{h}$ constitutes the current in the medium, and it is an essential part of the theory that—

$$\frac{d\dot{f}}{dx}+\frac{d\dot{g}}{dy}+\frac{d\dot{h}}{dz}$$

vanishes everywhere.

The current is connected with the components of the magnetic induction a, b, c by the equations—

$$\frac{dc}{dy}-\frac{db}{dz}=4\pi\dot{f} \qquad (2)$$

etc., and the magnetic force α, β, γ is given by

$$a=\mu\alpha \qquad (3)$$

etc., where μ is the coefficient of magnetic capacity.

a, b, c are also given in terms of a quantity known as the vector potential, the components of which are F, G, H, by the equations—

$$a=\frac{d\mathrm{H}}{dy}-\frac{d\mathrm{G}}{dz} \qquad (4)$$

etc., and from these it follows that

$$4\pi\mu\dot{f}=\frac{d\mathrm{J}}{dx}-\nabla^2\mathrm{F} \qquad (5)$$

etc., where

$$\mathrm{J}=\frac{d\mathrm{F}}{dx}+\frac{d\mathrm{G}}{dy}+\frac{d\mathrm{H}}{dz};$$

while the electromotive force at any point is also determined in terms of this same quantity F, G, H by the equations

$$P = -\frac{dF}{dt} - \frac{d\Psi}{dx} \quad . \quad . \quad . \quad . \quad . \quad (6)$$

etc., Ψ being the electrostatic potential. From this it follows that

$$\mu K \frac{d}{dt}\left(\frac{dF}{dt} + \frac{d\Psi}{dx}\right) - \nabla^2 F + \frac{dJ}{dx} = 0 \quad . \quad . \quad . \quad . \quad (7)$$

etc., and the vector F travels through the medium with velocity $1/\sqrt{K\mu}$. Now, the value of this quantity can be determined by experiment, and agrees very closely indeed with the velocity of light. Thus the vector potential, and in the same way the electric displacement and the magnetic induction, travel through the medium with a velocity, as nearly as we can say, identical with that of light.

Moreover, the electric displacement corresponding to this is in the wave front, and the same is the case with the magnetic induction a, b, c. By this motion energy is conveyed through the medium, the electrostatic energy depending on the electric displacement, the electro-kinetic on the magnetic induction, and the two can be shown to be equal. Thus the theory agrees with the undulatory theory of light in assuming the existence of a medium capable of becoming a receptacle of two forms of energy. Electric displacement and magnetic induction are, then, changes of condition which can be propagated in waves of transverse disturbances through the medium with a velocity practically identical with that of light. Maxwell's theory supposes that there is an intimate connection between the vibrations which constitute light and electric displacement; according to some of his followers the two are identical, though, so far as I can judge, that is not necessary to the theory as he left it.

Now, experiment shows that the value of μ is nearly the same for all media, so that it follows that on this theory the specific inductive capacity of a medium—the ratio of its inductive capacity to that of air—should be equal to the square of the refractive index. Experiments have shown that while this law is by no means true for all substances, it is sufficiently nearly so for many to render it probable that $\sqrt{K}$ gives the most important term of the index.

In estimating the value of the comparisons we must remember that while K is determined by observations lasting over an appreciable time, the refractive index depends on vibrations of great frequency; to compare the two, then, we have to adopt some dispersion formula, and find the value of the index for waves of infinite period, and this alone is a source of error.

Again, the equations for a crystalline medium are obtained by Maxwell, and he shows that the velocity of wave propagation is given by Fresnel's construction, while the electric displacement is in the wave front, and its direction is that of the axis of the ellipse which determines the velocity. The theory is not burdened with a wave of normal vibrations, and accounts quite simply for all the phenomena of double refraction.

§ 2. The theory of reflexion and refraction of electro-magnetic waves was first given by H. A. Lorentz,[1] who follows a method of attacking the

[1] Lorentz, *Schlömilch. Zeitschrift*, t. xxii.

problem which is due to Helmholtz.[1] This we shall consider later. It was also solved by J. J. Thomson,[2] so far as the isotropic media are concerned, and by Fitzgerald.[3]

Some further developments of the theory are given in a paper by the author of this report, and read before the Cambridge Philosophical Society.[4]

In this paper the general equations for the displacement and for the magnetic induction in a crystal are given. If $\bar{a}$, $\bar{b}$, $\bar{c}$ be the principal velocities given by the equation

$$\bar{a}^2=\frac{1}{\mu K_1},$$

etc., then

$$\frac{d^2f}{dt^2}=\bar{a}^2\,\nabla^2 f-\frac{d}{dx}\left(\bar{a}^2\frac{df}{dx}+\bar{b}^2\frac{dg}{dy}+\bar{c}^2\frac{dh}{dz}\right)\quad . \quad . \quad (8)$$

etc., while

$$\frac{d^2a}{dt^2}=\bar{a}^2\frac{d^2a}{dx^2}+\bar{b}^2\frac{d^2a}{dy^2}+\bar{c}^2\frac{d^2a}{dz^2}$$

$$-\frac{d}{dx}\left(\bar{a}^2\frac{da}{dx}+\bar{b}^2\frac{db}{dy}+\bar{c}^2\frac{dc}{dz}\right)\quad . \quad . \quad . \quad (9)$$

If a wave of electric displacement S′, in a direction in which the inductive capacity is K′, be traversing the medium, the electromotive force is $4\pi S'/K'$ in the direction of displacement, and $4\pi S' \tan\chi/K'$ along the wave normal, when χ is the angle between the ray and the wave normal.

§ 3. The surface conditions implied by the theory, and used by Lorentz, J. J. Thomson, Fitzgerald, and Glazebrook, are that the electric and magnetic displacements normal to the interface are continuous, while the electric and magnetic forces in the interface are also continuous.

The formulæ obtained are identical with those given by MacCullagh and Neumann, electric displacement being substituted for the ordinary displacement of the medium.

The theory has the very great advantage over the ordinary elastic solid theory that reflexion and double refraction are both explained by variations in the same property of the medium, viz. the inductive capacity. Variations in its value from medium to medium give rise to reflexion and refraction; variations in different directions within the same medium are the cause of double refraction.

§ 4. The theory has been applied by Lord Rayleigh to account for the various phenomena [5] connected with the scattering of light by a cloud of small particles. These are deduced satisfactorily from the theory on the supposition that μ, the magnetic capacity, is a constant through the two media, and that the effects are due to variations in the inductive capacity, while, when terms of the second order in $\Delta K/K$ are included, the scattered light does not vanish—the incident light being plane polarised—in a direc-

tion normal to the incident light, but in one inclined at an obtuse angle to that in which the light is travelling. Tyndall observed this effect when the particles scattering the light cease to be very small.

Chapter II.—Helmholtz's Theory.

§ 1. Helmholtz looks at the problem of the propagation of an electro-magnetic disturbance in a somewhat different manner, and a comparison of the two theories is given by the author of this Report.[1]

The electro-magnetic effects in the medium depend, according to Maxwell, on the values of F, G, H, the components of the vector potential, or, as Maxwell also calls it, of the electro-kinetic momentum, and if we integrate round a closed curve, the values of F, G, H satisfy the equation

$$\int \mathrm{F}dx + \mathrm{G}dy - \mathrm{H}\,dz = \iint \frac{i\cos\epsilon}{r}\, ds d\sigma \quad . \quad . \quad . \quad (10)$$

where ds is an element of the curve, i the current at any point at a distance r from ds, $d\sigma$ an element of the curve in which the current i is running, ϵ the angle between ds and $d\sigma$, and the integration on the right extends round the two curves s and σ.

From this we can show that

$$\mathrm{F} = \mu \iiint \frac{\dot{f}}{r}\, dx'dy'dz' + \frac{d\chi}{dx} \quad . \quad . \quad . \quad . \quad (11)$$

And if we put

$$\frac{df}{dx} + \frac{dg}{dy} + \frac{dh}{dz} = \frac{1}{4\pi} \nabla^2 \Phi \quad . \quad . \quad . \quad . \quad (12)$$

we find that

$$\nabla^2 \mathrm{F} - \frac{d\mathrm{J}}{dx} = -\,4\pi\mu\dot{f} + \mu\,\frac{d^2\Phi}{dxdt} \quad . \quad . \quad . \quad (13)$$

where

$$\mathrm{J} = \Phi\,\frac{d\mathrm{F}}{dx} + \frac{db}{dy} + \frac{d\mathrm{H}}{dz}.$$

Helmholtz, starting from the equation

$$\int \mathrm{F}dx + \mathrm{G}dy + \mathrm{H}dz = \iint \frac{i\cos\epsilon}{r}\, ds\, d\sigma,$$

investigates the most general form which F, G, H can have. He shows that we must write for $\frac{d\chi}{dx}$ of equation (11) the value

$$-\frac{1}{4\pi}\iiint \frac{(1-k)}{r}\,\frac{d^2\Phi}{dx'dt}\, dx'dy'dz' \quad . \quad . \quad . \quad (14)$$

where k is an unknown constant. Hence

$$\nabla^2 \mathrm{F} = -\,4\pi\mu\dot{f} + \mu\,(1-k)\frac{d^2\Phi}{dxdt} \quad . \quad . \quad . \quad (15)$$

and by comparing this with (13) we see that

$$\mathrm{J} = -\,\mu k\,\frac{d\Phi}{dt} \quad . \quad . \quad . \quad . \quad . \quad (16)$$

[1] Glazebrook, *Proc. Camb. Phil. Soc.* vol. vi. pt. ii. See also J. J. Thomson, 'Report on Electrical Theories' p. 133 of this volume.

If it be necessary that J should vanish, then k or $\frac{d\Phi}{dt}$ must be zero. According to Helmholtz, however, J is not necessarily zero, and the equation to determine it is—

$$\mu k \mathrm{K} \frac{d^2 \mathrm{J}}{dt^2} = \Delta^2 \mathrm{J} \quad . \quad . \quad . \quad . \quad . \quad (17)$$

so that J, and therefore Φ, is propagated through the medium as a wave of normal disturbance with the velocity

$$\sqrt{\frac{1}{k\mu \mathrm{K}}}.$$

On Helmholtz's theory there may therefore be a normal wave in addition to the transverse wave. Helmholtz's theory becomes Maxwell's if we put $\Phi = 0$, and then unless the value $k = \infty$ is admissible $\mathrm{J} = 0$, and there is no normal wave. If $k = 0$ there will still be no normal wave, for its velocity will be infinite.

When we consider the problem of double refraction, we can show that all the possible directions of vibration L, M, N corresponding to a given wave normal l, m, n are given by the equation—

$$\frac{l}{\mathrm{L}} (\bar{b}^2 - \bar{c}^2) + \frac{m}{\mathrm{M}} (\bar{c}^2 - \bar{a}^2) + \frac{n}{\mathrm{N}} (\bar{a}^2 - \bar{b}^2) = 0 \quad . \quad . \quad (18)$$

There are therefore, in general, an infinite number of such directions. If, however, we are to assume that there are only two, and those the two given by Fresnel's theory, we must have $l\mathrm{L} + m\mathrm{M} + n\mathrm{N} = 0$. Thus Maxwell's solenoidal condition,

$$\frac{df}{dx} + \frac{dg}{dy} + \frac{dh}{dz} = 0 \quad . \quad . \quad . \quad . \quad . \quad (19)$$

is a necessary and sufficient condition to give Fresnel's construction.

Chapter III.—Dispersion, etc.

According to the theory as left by Maxwell, waves of all lengths travel at the same rate. Dispersion does not come into consideration. This question has been dealt with by Willard Gibbs [1] and H. A. Lorentz.[2]

§ 1. According to Gibbs's views the displacements of which we are cognisant in the phenomena of light are the average displacements taken through a space which is small in comparison with the wave length, but contains many molecules of the body. The real displacement at each point of such an elementary space probably differs considerably from the average value, and a complete theory should take into account the two. This is done in Gibbs's paper. The average displacements being ξ, η, ζ, the complete displacement is taken as $\xi + \xi'$, &c. ξ', η', ζ' are denoted as the irregular parts of the displacements. It is shown that ξ', η', ζ' are linear functions of ξ, η, ζ; they are therefore of the same period, and the phase of the irregular displacement throughout the element Dv is the

[1] J. W. Gibbs, *American Journal of Science*, vol. xxii. April, 1882.
[2] H. A. Lorentz, *Wied. Ann.* t. ix.; *Schlömilch. Zeitschrift*, t. xxiii.

same as that of the regular or average displacement, but the relations between ξ, η, ζ and ξ', η', ζ' change rapidly as we pass from point to point of the element.

The velocity of wave propagation is found by equating the maximum potential and kinetic energies of the medium. It is shown that the equations lead to Fresnel's construction in the case of a crystal if the solenoidal condition be assumed, while the relation between μ the refractive index and λ the wave length is given by

$$\frac{1}{\mu^2}=\frac{\mathrm{H}}{2\pi k^2}-\frac{2\pi_1\mathrm{H}'}{\lambda^2} \quad . \quad . \quad . \quad . \quad (20)$$

H, k, and H′ being constants. The objection which Briot made to Cauchy's theory of dispersion may be made to this. We should expect dispersion in a vacuum as well as in ordinary transparent media.

The properties of circularly polarising media are discussed in a second paper,[1] in which ξ', η', ζ' are treated as linear functions of ξ, η, ζ and their differential co-efficients; and in a third paper the fundamental equations are re-established in rather a more general form than that given by Maxwell.

The generality is gained partly by dealing with the average values of the various quantities, and partly by supposing that the relation between the E.M.F. and displacement is given by

$$[\mathrm{E}]=\phi\,[\ddot{\mathrm{U}}]+\psi\,[\mathrm{U}] \quad . \quad . \quad . \quad . \quad (21)$$

ϕ and ψ being two arbitrary functions, and [ ] indicating that the average value is taken. In the simple theory ϕ is a constant, and equal to $4\pi/\mathrm{K}$, and ψ zero, and this will not give dispersion.

There seems, however, to be no reason—as has been pointed out by Professor Fitzgerald—against applying to the oscillations of the electro-magnetic field the methods and reasoning developed in the third part of this report. Almost the whole of the work can be translated into the language of the electro-magnetic theory at once. Periodic electric displacement in the ether will produce periodic electric displacement in the matter, and the relations between the two will depend on the ratio of the period of the ether vibrations to the possible free periods of the electric oscillations in the matter molecules; and it is not difficult to see how the action between the two might depend on the relative electrical displacements and their differential coefficients.

§ 2. Maxwell[2] has given a theory of the magnetic rotation of the plane of polarisation on this theory. He assumes (1) that the effect of magnetic force is to set up molecular vortices in the medium; (2) that the components of the magnetic force obey the same law as the components of the strength of a vortex in hydrodynamics; and (3) that there arises in the value for the kinetic energy of the medium a term of the form $2\mathrm{C}(\alpha\omega_1+\beta\omega_2+\gamma\omega_3)$, ω_1, ω_2, ω_3 being the components of the angular velocity, and α, β, γ of the magnetic force.

For the case of waves travelling parallel to z the kinetic energy is shown to be

$$\mathrm{T}=\tfrac{1}{2}\rho\,(\dot\xi^2+\dot\eta^2+\dot\zeta^2)+c\gamma\left(\dot\eta\,\frac{d^2\dot\xi}{dz^2}-\dot\xi\frac{d^2\dot\eta}{dz^2}\right) \quad . \quad . \quad (22)$$

[1] J. W. Gibbs, *American Journal of Science*, vol. xxiii. June, 1882.
[2] Maxwell, *Electricity and Magnetism*, vol. ii. p. 40.

and the equations of motion,

$$\rho \frac{d^2\xi}{dt^2} + c\gamma \frac{d^3\eta}{dz^2 dt} = A_0 \frac{d^2\xi}{dz^2} + A_1 \frac{d^4\xi}{dz^4} +, \text{ etc.} \quad . \quad . \quad (23)$$

From this it follows that the rotation per unit length is

$$\theta = mc\gamma \frac{i^2}{\lambda^2}\left(i - \lambda \frac{di}{d\lambda}\right) \quad . \quad . \quad . \quad . \quad (24)$$

where i is the index of refraction, and this formula agrees well with experiment.

It should be noticed that in obtaining this formula Maxwell deals with the displacements of an ordinary medium; the forces assumed are those arising from the elastic reactions of this medium, the vortex motion in which is connected with the magnetic force. The displacements are not treated as identical with the electric displacements, nor is any indication given of the connection between the two.

§ 3. Fitzgerald, in the paper already mentioned, applies the theory to the case of reflexion from a magnetic medium. He finds that when plane polarised light is reflected directly from such a medium, the reflected light is slightly elliptically polarised. This is not in accordance with Kerr's experimental result, but Fitzgerald treats the iron as a transparent, or nearly transparent, substance with a real refractive index.

§ 4. It was shown by E. H. Hall that when a current passes across a conductor in a magnetic field an electromotive force is produced whose strength is proportional to the product of the current and the strength of the field, and whose direction is at right angles to the plane containing the current and the field.

By introducing into the equations for the electromotive force terms expressing this, so that they become

$$P = -\frac{dF}{dt} - \frac{8\pi\mu\bar{C}}{\rho}(\gamma\dot{g} - \beta\dot{h}) \quad . \quad . \quad . \quad . \quad (25)$$

etc., Prof. Rowland [1] has calculated the magnetic rotation of the vectors F, G, H, and, on the assumption that a similar effect will be produced in a dielectric, arrives at the same formula as that given by Maxwell.

§ 5. The main difficulty of the theory, and the one which stands most in the way of its general acceptance, is the difficulty of forming a clear physical idea of what electric displacement is, and various analogies have been suggested with a view to rendering the difficulty less serious. One of these, due to Helmholtz,[2] is developed in a paper on the molecular vortex theory of electro-magnetic action.[3] It is shown there that, if the components of the magnetic force be identified with the molecular rotations in a continuous medium in which the displacements are ξ, η, ζ, then the components of the electro-kinetic momentum are equal to $\frac{1}{2}\mu\dot{\xi}$, etc.; and the equations of the electrical field in a conductor would imply that the medium in the conductor has the properties of a viscous fluid, while in a dielectric, so far as the motion to which the undulatory effects are due is

[1] Rowland, *Phil. Mag.* April, 1881.
[2] Helmholtz, *Crelle Journal*, t. lxxii.
[3] Glazebrook, *Phil. Mag.* June, 1881.

concerned, its properties are those of an elastic solid in which the electrical displacement f is given by

$$8\pi f = -\nabla^2\xi + \frac{d}{dx}\left(\frac{d\xi}{dx}+\frac{d\eta}{dy}+\frac{d\zeta}{dz}\right) \quad . \quad . \quad . \quad (26)$$

The objection that it is impossible to maintain a continuous molecular rotation in an elastic solid may be made to this analogy. It seems, however, possible that, as suggested by Professor Stokes when considering the problem of aberration, the ether may behave as a perfect fluid for all motions involving more than a very small relative displacement of its parts, while for such small displacements as are contemplated in the theory of light it has, in a dielectric, an appreciable rigidity. In a conductor the effects of this rigidity, if it exist, are masked by the more powerful effects of the viscosity. The fluid is no longer perfect.

Chapter IV.—Rowland's Theory of the Propagation of Plane Waves.

§ 1. The propagation of waves of electro-magnetic disturbance from a given source has been recently very fully considered by Professor Rowland,[1] and we proceed to give some account of his paper.

Rowland considers very generally the solution of the equations—

$$\frac{d^2F}{dt^2} = V^2\nabla^2F, . \quad . \quad . \quad . \quad . \quad (27)$$

etc., and allied equations given by the system

$$F_{m+1} = \frac{dH_m}{dy} - \frac{dG_m}{dz} \quad . \quad . \quad . \quad . \quad (28)$$

so that F, G, H satisfy the solenoidal condition. He puts

$$F_0 = C_n\rho^n\Phi_{-(n+1)}\, e^{(a-ib)(\rho-Vt)},$$

$\Phi_{-(m+1)}$ being a spherical harmonic, and C_n a function of ρ.

He finds

$$\frac{d^2C_n}{d\rho^2} + 2\,(a-ib)\frac{dC_n}{d\rho} - \frac{n(n+1)}{\rho^2}C_n = 0 \quad . \quad . \quad (29)$$

whence

$$C_n = C_0\left\{1 - \frac{n}{2}\frac{n+1}{c\rho} + \frac{n\,(n^2-1^2)}{2.4}\frac{(n+2)}{c^2\rho^2} + . \quad . \quad . \quad .\right\} \quad (30)$$

where $c = a - ib$.

He then takes, as a special solution,

$$F_0 = C_n\rho^n\frac{d\Phi_{-n}}{dx}e^{c(\rho-Vt)} \quad . \quad . \quad . \quad . \quad (31)$$

and

$$F_1 = cC_{-1}\rho^{n-1}\left\{y\frac{d\Phi_{-n}}{dz} - z\frac{d\Phi_{-n}}{dy}\right\}e^{c(\rho-Vt)} \quad . \quad . \quad (32)$$

etc., and treats the case of symmetry round the axis of x, for which

$$\Phi_{-n} = \frac{(-1)^nQ_{n-1}}{\rho^n n!},$$

Q_{n-1} being a zonal harmonic with the axis of x for axis.

[1] Rowland, *American Journal of Mathematics*; *Phil. Mag.* June, 1884.

Let θ be the angle between this direction and that to the point at which the disturbance is required, ρ the distance to the point, and α the angle between the plane $xO\rho$ and some fixed plane.

Let Θ', Θ'' denote disturbances perpendicular to the radius vector in the plane $xO\rho$,

P′ P″ along the radius vector, and

N′ N″ normal to the wave plane $xO\rho$.

Then it follows that if we have small electric displacements $X'e^{-ib(R-Vt)}$ parallel to x throughout the small sphere ($\frac{4}{3}\pi R^3 = dv$), that

$$\left.\begin{aligned} \Theta' &= -\frac{2C_0+C_2}{C_0}\frac{b^2X'}{8\pi\rho}\sin\theta e^{-ib(\rho-Vt)}dv \\ P' &= \frac{C_1}{C_0}\frac{3ibX'}{4\pi\rho^2}\cos\theta e^{-ib(\rho-Vt)}dv \end{aligned}\right\} \quad . \quad . \quad (33)$$

$$N' = \Theta'' = P'' = 0$$

$$\left.N'' = \frac{3b^2X'\sin\theta}{2\pi\rho}\frac{C_1}{C_0}e^{-ib(\rho-Vt)}dv\right\} \quad . \quad . \quad . \quad . \quad (34)$$

where

$$\left.\begin{aligned} C_1 &= C_0\left(1-\frac{i}{b\rho}\right) \\ C_2 &= C_0\left(1-\frac{3i}{b\rho}-\frac{3}{b^2\rho^2}\right) \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (35)$$

This agrees with the results given by Stokes and Lord Rayleigh, already quoted,[1] N″ being proportional to the rotation. The effect of a general arbitrary electric and magnetic displacement is then found.

In considering the optical problem it is pointed out that electric displacement is always accompanied by magnetic, and that the effects of the two must be considered, and according to the views of Professor Rowland the two must be considered independently. From the relation between the electrostatic and electromagnetic energy, it follows that if there be an electric displacement $X'e^{ibVt}$ there will be a magnetic $Y''e^{ibVt}$ where

$$Y'' = \frac{4\pi}{V\kappa}X'.$$

The electric displacement at any other point of space is found and expressed as below. Let the origin be the point at which X′, Y″ act; the axis of z the normal to the plane of $X'aY''$; ρ the direction in which the effect—at a point A—is required; the angle $zOA = \theta$, and the angle between zOA and $zOx = \phi$; and let P′, Θ′, Φ′ be the displacements along OA, and normal to θ and ϕ.

Then

$$\left.\begin{aligned} \Theta' &= \frac{3b^2X'V}{8\pi\rho}\cos\phi\left[(1+\cos\theta)\left(1-\frac{i}{b\rho}\right)-\frac{\cos\theta}{b^2\rho^2}\right]e^{-ib(\rho-Vt)} \\ \Phi' &= -\frac{3b^2X'V}{8\pi\rho}\sin\phi\left[(1+\cos\theta)\left(1-\frac{i}{b\rho}\right)-\frac{1}{b^2\rho^2}\right]e^{-ib(\rho-Vt)} \\ P' &= \frac{3ibX'V}{4\pi\rho^2}\sin\theta\cos\varphi\left[1-\frac{i}{b\rho}\right]e^{-ib(\rho-Vt)} \end{aligned}\right\} (36)$$

[1] See p. 201.

And we can show that in the value of Θ' it is the 1 in $(1 + \cos\theta)$ which comes from the assumed magnetic disturbance, while in Φ' it is the $\cos\theta$ in the same term.

The magnetic disturbance produces no effect in the value of P′. Neglecting the magnetic disturbance we arrive at Stokes's result for the effect of a disturbance $X'e^{ibVt}$ on the medium, which is used by Rayleigh in the paper on the blue of the sky.

Now we may note that the result of the experiments on scattered light seems to disprove this hypothesis of Rowland's as to the necessity of considering the two disturbances, for according to him the intensity is the same at all points in the plane xy at the same distance from O. This is not true; the intensity varies as $\sin^2\alpha$ if α is the angular distance of the point from the axis of x. Again, it is true, of course, that the magnetic disturbance accompanies the electric, but it accompanies it as a consequence. If we produce, by some impressed force, a variable electric displacement at a point in the medium, and calculate the effect due to this, we have done all that is necessary. There will, it is true, be magnetic displacement, but it can be calculated from the electric.

Rowland's results do not apply to the case of a wave being propagated through an aperture, for in this case we have no right to assume that the disturbance produced by an element is symmetrical round the direction of vibration. We have not a single particle or an indefinitely small sphere vibrating and sending out its effects in spherical waves; we have a state of motion coming in from behind the aperture, and being continually propagated across it at a given point P and at time t_0, we must consider the circumstances at any point O of the aperture at a time t_0 such that $OP = b(t - t_0)$. For these will be the initial circumstances so far as we are concerned; and at this time t_0, O has an initial velocity and an initial displacement. Both these require to be considered in dealing with the question, and we have to adopt Stokes's[1] method of solution, and we again arrive at his theorems with regard to the relation between the direction of vibration and the direction of diffraction.

§ 2. The electro-magnetic theory, if we accept its fundamental hypotheses, is thus seen to be capable of explaining in a fairly satisfactory manner most of the known phenomena of optics. The great difficulty is, as we have said, to account for the properties which the medium must have in order to sustain electrical stresses. These consist in an electrostatic field of a hydrostatic pressure $KR^2/8\pi$, combined with a tension $KR^2/4\pi$ along the lines of force; R being the resultant electrical force, and K the inductive capacity. There will therefore be a difference of pressure in different directions in the ether.

Combined with this difficulty there is another of a similar kind, that of realising mechanically what electric displacement is, of forming for oneself a physical idea of a change of structure in some medium of unknown properties which shall obey the laws implied by the various equations satisfied by the components of electrical displacement.

Optical effects are certainly due to changes, periodic in space and time, of some properties of a medium which we call the ether. Electromagnetic effects are also due to variations in properties—it may be the same as those which give rise to light—of the same ether. When the

[1] On this point reference has already been made, see p. 206.

electro-magnetic effects become rapidly periodic they travel with the velocity of light, and the direction to which the change of property is related is in the wave front, at least for isotropic media.

The rigidity or quasi-rigidity through which the medium has the power of propagating these transverse waves of small displacement may be given to it through other motions which are going on independently of the light. The free passage of the planets through space proves that it can have little if any viscosity or rigidity, though, according to the views of Professor Stokes, while behaving as a perfect fluid for all appreciable motions, it might conceivably be rigid for the very small displacements in a light-wave. Taking Sir W. Thomson's estimate of the density of the ether as about 10^{-22} grammes per cubic centimetre, the rigidity required for the propagation of light would be about 10^{-1}. The rigidity of glass is about $2{\cdot}5 \times 10^{11}$. While it might, then, be conceivable that the ether should have this very small rigidity and yet offer no appreciable resistance to the earth's motion, it is difficult to reconcile this with its power of standing electric stress, and we are forced to conclude that the change implied in electric displacement is much more than a mechanical displacement of the molecules of a perfect fluid. A quasi-rigidity might be conferred on the fluid by filling it with vortices, and it might thus become capable of conveying transverse waves and of standing electric stress. Electric and magnetic polarisation would then consist in definite arrangements of the vortex rings or filaments. Changes in these arrangements, or in some of the properties connected with them, would constitute electric and magnetic displacements, and possibly also light.

We should then have a complete electro-magnetic theory of optics, or rather a complete theory of the ether embracing electro-magnetism and optics, but towards this theory our present knowledge has made only a small advance.

Report of the Committee, consisting of Professors RAMSAY, TILDEN, MARSHALL, *and* W. L. GOODWIN (*Secretary*), *appointed for the purpose of investigating certain Physical Constants of Solution, especially the Expansion of Saline Solutions.*

YOUR Committee have to report as follows:

They have obtained apparatus for determining the rates of expansion of saline solutions from $-20°$ C. to $+60°$ C.

They have devised experiments for determining the distribution of a weighed quantity of water between molecular weights of two salts, the three substances being placed in separate vessels in the same enclosed space kept at a constant temperature.

But further progress in either of these directions was interrupted by the continued illness of one of the Committee.

Your Committee respectfully ask for reappointment.

Third Report of the Committee, consisting of Professors WILLIAMSON, DEWAR, FRANKLAND, CRUM BROWN, ODLING, *and* ARMSTRONG, Drs. HUGO MÜLLER, F. R. JAPP, *and* H. FORSTER MORLEY, *and* Messrs. A. G. VERNON HARCOURT, C. E. GROVES, J. MILLAR THOMSON, H. B. DIXON (*Secretary*), *and* V. H. VELEY, *reappointed for the purpose of drawing up a statement of the varieties of Chemical Names which have come into use, for indicating the causes which have led to their adoption, and for considering what can be done to bring about some convergence of the views on Chemical Nomenclature obtaining among English and foreign chemists.*

AN account of the authorship of some of the various systems of nomenclature which have been devised for the purpose of distinguishing between compounds formed by the union of the same elements in different proportions, has been given in the 'Historical Notes' prefixed to the Second Report of this Committee. Among these systems the use of the terminations *ous* and *ic*, to denote respectively lower or higher degrees of saturation of one element or group with another element or group, is perhaps that which has met with the widest acceptance. This system further directs that when electro-negative groups, the names of which end in *ous* and *ic*, unite with electro-positive groups to form salts, these terminations are to be changed into *ite* and *ate* respectively.

Before proceeding to discuss the practical application of this system, it may be well to point out, as a minor etymological detail, that the literal meaning of the terminations *ous* and *ic* has altered since they were first employed. Thus *ous* (Latin *osus*) ought to denote, on the part of the compound, *richness in* that element to the name of which the termination is attached. For example, *cuprous* (*cuprosus*) means 'rich in copper': *cuprous* oxide is primarily an oxide which is *richer in copper* than *cupric* oxide, and only by implication an oxide which is *poorer in oxygen.* This implied signification is, however, that in which the name *cuprous oxide* is nowadays employed. A curious result of this change of literal meaning is to be found in the use of the prefix *hypo* to denote a still lower degree of saturation than that expressed by *ous.* Thus the name *hyponitrous acid* is taken to denote an acid containing still less oxygen than nitrous acid; whereas *hyponitrous* really means 'less rich in nitrogen,' which is the very opposite. Had the etymology been logically carried out, the prefix ought to have been *hyper.* A similar confusion of ideas is displayed in the use of the prefixes *hyper* and *per* at the other end of the scale; in place of these, *hypo* ought to have been employed. *Perchromic acid* does not, as its name literally taken signifies, contain more chromium than *chromic acid*: it contains less, and ought consequently to have been termed *hypo*-chromic acid.

It need hardly be said that it would be ill-advised to attempt to change a system so firmly established as that involved in the present use of these prefixes *hypo* and *hyper*; and in the above remarks on the etymology of the subject, nothing of the kind is intended. No ambiguity can arise from the use of terms about the meaning of which everyone is agreed, and their mere etymological accuracy is, in view of this all-important consideration, of secondary importance.

The following list will show the application of the *ic* and *ous* nomenclature to salts and salifiable oxides:—

I. *List of Salts where Two or more Series of Compounds are formed.*[1]

Name denoting metallic radical of salt	Formula of corresponding oxide	Name denoting metallic radical of salt	Formula of corresponding oxide
Cuprous	Cu_2O	Chromous	CrO
Cupric	CuO	Chromic	Cr_2O_3
Mercurous	Hg_2O	Uranous	UO_2
Mercuric	HgO	Uranic (Uranylic)	UO_3
Aurous	Au_2O	Manganous	MnO
Auric	Au_2O_3	Manganic	Mn_2O_3
Thallous	Tl_2O	Ferrous	FeO
Thallic	Tl_2O_3	Ferric	Fe_2O_3
Stannous	SnO	Cobaltous	CoO
Stannic	SnO_2	Cobaltic	Co_2O_3
Cerous	Ce_2O_3	Platinous	PtO
Ceric	CeO_2	Platinic	PtO_2

Names corresponding with *platinous* and *platinic* would be applied to the corresponding oxides and salts of the other metals of the platinum group—distinguishing, however, the other oxides and salts of this group by numeral or other designations.

The designations given in this Table to the various higher and lower series of salts and salifiable oxides have been employed with almost complete uniformity by all chemists who have adopted this system of nomenclature.

As a metal rarely—if ever—forms more than two salifiable oxides, the *ous* and *ic* terminations generally suffice for purposes of distinction so far as the salts of metals are concerned.

The practice of further employing these terminations in the case of acid-forming oxides does not lead to confusion, since these oxides are distinguished by the name *anhydride* (or *acid*). Thus we have

CrO	Cr_2O_3	CrO_3
Chromous oxide.	Chromic oxide.	Chromic anhydride (Chromic acid.)

Indifferent oxides have frequently been classified and named by regarding them as compounds of salifiable, with acid-forming oxides, Cr_2O_4 being termed *chromic chromate.* For stages lower than *ous*, the prefixes *hypo* and *sub* are employed. Custom appears to have restricted *hypo* chiefly to acids and to acid-forming oxides, *sub* to salifiable and to indifferent oxides.

With regard to the termination *ous*, the minor question arises, how far this termination ought to be written in the forms *ious* and *eous.* The answer is: as seldom as possible. 'Cupreous' has generally given way to 'cuprous'; no one writes 'chrom*i*ous' (although the name of the metal is 'chrom*i*um'); and there is no reason why such names as 'ruthenious' and 'iridious' should not equally be shorn of their superfluous penultimate syllable.

A further question, concerning which considerable difference of opinion has prevailed, is whether any *ous* or *ic* terminations ought to be employed in the names of salts of which only one class is known—thus *magnesic sulphate* instead of *magnesium sulphate.* There is something to

[1] In this list the term 'salt' is taken to include 'haloïd salts,' but to exclude the halogen compounds of those elements whose oxides do not yield oxy-salts with acids.

be said here for both systems; and, as the diversity of practice does not lead to confusion, and consequently does but little harm (beyond in each case offending the ears of those accustomed to the opposite system), the question need not be regarded as a vital one. Objections which have been urged against the use of any termination in such cases are that chemists have not always been able to agree as to which termination is to be used in a given case, and that, apart from this, the practice causes beginners erroneously to surmise the existence of a second series of salts. The objection on the other side is that the omission of the terminal 'ic' breaks the uniformity of the system and leads beginners to suppose that barium sulphate, for instance, has a different constitution from cupric sulphate. In the case of carbon compounds, on the other hand, there is a distinct advantage in affixing *ic* to the names of the positive radicals in ethereal salts. A neglect of this precaution leads to ambiguity—at all events in the *spoken* name. Thus, though there is no ambiguity in the name *ethyl phenylacetate* when written, yet the ear cannot distinguish between it and *ethylphenyl acetate.* This ambiguity is obviated by the use of the termination *ic*: thus, *ethylic phenylacetate* and *ethylphenylic acetate.*

In the use of the terminations *ous* and *ic* to distinguish different series of *acids and acid-forming oxides*, the practice of chemists has also been very uniform. Indeed, with the exception of one or two isolated cases almost perfect unanimity has prevailed.

To sum up, the *ous* and *ic* terminations when employed for purposes of distinction in cases where two series of oxides, acids, salts, &c., are known, have been almost free from ambiguity, and for this reason deserve to be retained. On the other hand, in cases where only one series is known, those chemists who have employed one or other of these terminations have occasionally differed as to which ought to be used: the difficulty may be solved, as it has been done by some chemists, by avoiding the use of any termination in such cases.

In complex cases where the above modes of naming prove inadequate, recourse may be had to numeral designations. These appear especially admissible in cases where an oxide occurs which is intermediate between the *ous* and *ic* stage, and at the same time cannot be classed as a compound of oxides already classified and named.

In applying numeral designations, it is most important to select only such as are free from hypothesis and which afford correct information. In this respect, chemists appear of late years not to have been sufficiently careful. As an example, *arsenious oxide* may be quoted; this compound is frequently termed 'arsenic trioxide,' the formula being written As_2O_3, and it is tacitly assumed that the molecule contains three oxygen atoms. There are three objections to this name:—(1) That, assuming the formula on which it is based to be correct, it affords no information as to the number of *arsenic* atoms associated with the *three* oxygen atoms; (2) that it involves the assumption that arsenious oxide does not vary in molecular weight, whatever its physical state; and (3) that the formula of *gaseous* arsenious oxide is As_4O_6.

In employing numeral designations to indicate molecular composition in cases where this is established, it is therefore important to express the number of atoms of each constituent element, as *dicarbon hexachloride*, $C_2 Cl_6$. But in the case of solid and liquid bodies of which the molecular weight is either unknown or may vary with temperature, the name should indicate merely the relative proportions in which the constituents are associated; or, more explicitly, the name should indicate the propor-

tion of the radical associated with what may be termed the characteristic element of the compound. No difficulty occurs in the case of the chlorides, or analogous compounds with the monad elements generally, these being termed mono-, di-, tri-, tetra-, penta-, or hexa-chloride, &c., according as combination is in the proportion of 1, 2, 3, 4, 5, or 6 atoms of chlorine to 1 atom of the characteristic element. The application of this system would involve the use of the names tin dichloride and iron trichloride (not sesqui-chloride) for stannous and ferric chlorides respectively, names which accurately express the relative proportions of chlorine to metal in these compounds without any hypothesis as to their molecular composition —a composition, which in the case of the former compound, at all events, certainly depends on temperature. It will, however, involve a slight departure from the existing practice when applied to oxides, sulphides, and other compounds of polyad elements; thus oxides of the type $(R_2)''O$ would be termed *hemi*-oxides, since they consist of the characteristic element and oxygen in the proportion of *one* atom of the former to *half* an atom of the latter. Oxides of the type $(R_2)^{vi}O_3$ would be termed *sesqui*-oxides, since the characteristic element and oxygen are present in the proportion of *one* of the former to *one and a half* of the latter. Oxides of the type $R_2\,O_5$ would be termed *sesterti*-oxides, as they contain oxygen and the characteristic element in the proportion of *two and a half* atoms of the former to *one* of the latter. Oxides of the types RO, RO_2, RO_3, and RO_4, would be termed respectively *mono-*, *di-*, *tri-*, and *tetr*-oxides.

Acid Salts.

There are two distinct classes of salts to which this name has been given:—

1. Salts with two or more metals, one of the metals being hydrogen.
2. Salts formed from these by the removal of water.

Until comparatively lately, no attempt was made to give distinctive names to these two classes, except that sometimes the words hydratic and anhydrous were used to distinguish them. The distinctive names—pyrophosphate, metaphosphate—which Graham gave to the two sets of anhydrous acid phosphates were founded on the supposition that the phosphoric acid (PO_5) existed in them in two modifications, different from the acid of the ordinary phosphates.

The nomenclature used by nearly all chemists from the beginning of this century until about 1860 is illustrated on tables 3–6. Acid salts in which for the same quantity of base there is 2, 3, . . . &c. times as much acid as there is in the normal salt are called bi——ate, ter——ate, &c. (in German, doppelt (or zweifach)——saures Salz, dreifach——saures Salz, &c.) In English and French the Latin adverbial numerals *bis* or *bi*, *ter*, &c. seem always to have been used until about twenty years ago, when Greek adverbial numerals were introduced for the anhydrous acid salts. Watts's Dictionary and Naquet are the first English and French authorities in which we have observed this change.

Basic Salts.

There are two distinct classes of salts to which this name has been given:—

1. Salts with two or more salt radicals, one of the salt radicals being hydroxyl.
2. Salts formed from these by the removal of water.

These were not distinguished by name until quite recently, and are still very often confused.

The nomenclature in general use is illustrated on tables 8–12.

Basic salts of oxygen acids in which for the same quantity of base there is $\frac{1}{2}$, $\frac{1}{3}$, &c. as much acid as there is in the normal salt are called di——ate, tri (or tris)——ate, &c. (in German, halb——saures Salz, drittel——saures Salz, &c.)

Basic salts of oxygen acid were also named by the proportion of base to acid, the proportion in the normal salt being taken as unity—bibasic, terbasic, &c. salts (in German, zweifach, dreifach, etc. basische Salze). Thus *tris*nitrate (drittel saures salpetersaures Salz) is the same as *ter*basic nitrate (dreifach basisches salpetersaures Salz), Latin adverbial numerals being used for multiples, and Greek adverbial numerals for submultiples.

The compounds of basic oxides with haloïd salts (corresponding to the basic salts of the oxygen acids) are variously named; thus, oxychloride, bisoxychloride, basic chloride, bibasic chloride. The numerals here refer not to the number of atoms of oxygen and halogen, but to the proportion of metal combined with oxygen and halogen respectively (or perhaps more correctly to the proportion of *equivalents* of oxygen and halogen); thus $2PbO.PbCl_2$ is bisoxychloride, or bibasic chloride. It is to be noted that corresponding basic haloïd and oxygen salts have not the same numeral; as—

$PbO.PbCl_2$ is basic chloride (einfach basisches Chlorid).

$PbO.Pb(NO_3)_2$ is bibasic nitrate (zweifach basisches Salz), because it is $2PbO.N_2O_5$.

$2PbO.PbCl_2$ is bibasic chloride (zweifach basisches Chlorid).

$2PbO.Pb(NO_3)_2$ is terbasic nitrate (dreifach basisches Salz), because it is $3PbO.N_2O_5$.

Sulphur Salts.—Table 14.

These have sometimes, especially in German, been named as double sulphides, but usually, in Latin, English, French, and recently also in German, follow the names of the corresponding oxygen salts.

Sulphur Basic Salts.—Table 13.

Compounds of normal salts with sulphides of the metal. These were discovered by H. Rose, and called by Berzelius sulphur basic (schwefel basisch), as corresponding to the compounds of normal salts with the basic oxide. This nomenclature has not been generally adopted, and, as will be seen from the table, there is little uniformity in naming these substances.

Double Salts.

With very few exceptions, these may be classified in two sets. 1. With a common salt radical. 2. With a common metal. 1. With a common salt radical. Here again there are two kinds. (*a*) Salts of polybasic acids. (*b*) Compounds of two haloïd salts, or of a haloïd salt, with a compound of a halogen and a non-metallic element.

(*a*) These are named consistently with the names of the simple salts; as phosphate of magnesia and ammonia, phosphorsaure ammoniak-magnesia, magnesium ammonium orthophosphate, ammonic magnesic phosphate, or, with what may perhaps be called an adverbial modification of the first adjective, ammonio-magnesic phosphate.

(*b*) Of these we may take as examples $2KF, SiF_4$; $2KCl, PtCl_4$; $2KCN, Pt(CN)_2$; KF, BF_3; $KCl, AuCl_3$; $4KCN, Fe(CN)_2$; $3(KCN), Fe(CN)_3$. See Tables 15, 16, 17.

These have been named on three different principles :—

(α) As double fluorides, chlorides, etc.; for instance, fluoride of silicon and potassium, fluorkieselkalium.

(β) As compounds of the positive metal with a compound salt radical; for instance, ferrocyanide of potassium, silicofluoride of potassium, kieselfluorkalium.

(γ) As analogues of oxygen salts; for instance, fluosilicate of potassium, potassium fluosilicate, potassium chlorplatinate, chloraurate, cyanaurate.

The third system seems only to be used when there is really a corresponding oxygen compound.

2. With a common metal. As a well-known substance mentioned by most systematic writers, emerald green has been selected—table 18. It will be seen that where a name is given, it is either acetate and arsenite, or a combined name, acetoarsenite, or arsenigessigsaures Salz.

21. Un véritable bisulphate ($NaO.2SO^3$).
22. —
23. Anhydrosulphate of sodium or anhydrous bisulphate of sodium ($Na_2S_2O_7 = Na_2SO_4,SO_3 = Na_2O, 2SO_3$) 1875.
24. Disulfate de soude.
25. —
26. Anhydro bisulphate (SO_4Na_2,SO_3).
27. Sodic disulphate ($Na_2S_2O_7$).
28. Anhydrosulfate.
29. —
30. Neutrales Kalium Pyrosulfat.
31. Dischwefelsaures Natron

$$\left(O\begin{cases}SO_2ONa\\SO_2ONa\end{cases}\right)$$

32. Pyrosulphate ($Na_2S_2O_7$ or Na_2SO_4, SO_3).
33. Sodic pyrosulphate ($Na_2S_2O_7$).
34. Sodium disulphate ($Na_2S_2O_7$).
35. Sodic pyrosulphate ($S_2O_5Nao_2$).
36. Sodium disulphate $\left(O\begin{cases}SO_2ONa\\SO_2ONa\end{cases}\right)$.

V.

1. (Alkaline chromats.)
2. Chromate of potash [red colour].
3. Bichromate of potash.
4. (Not distinguished from chromates.)
5. Bichromate of potash.
6. Bichromate of potassa ($2Chr' + P$).
7. Bichromas kalicus ($\dot{K}\dddot{C}r_2$).
8. Bichromate of potassa ($2Chr' + P$).
9. Bichromate of potash ($KO,2CrO_3$).
10. Not mentioned.
11. " "
12. Zweifach chromsaures Kali.
13. Doppeltsaures od. rothes chromsaures Kali ($KO,2CrO_3$), 1859.
14. —
15. Bichromate of potash ($KO + 2CrO_3$).
16. Bichromate of potash ($KO,2CrO_3$), 1858.
17. Bichromate de potasse.
18. Bichromate of potassa ($KO,2CrO_3$).
19. Zweifach od. rothes chromsaures Kali ($KaO,2CrO_3$).
20. Bichromate of potash ($KO,2CrO_3$).
21. Bichromate de potasse.
22. —
23. Acid chromate of potassium, dichromate of potassium, or bichromate of potash ($K_2O.2CrO_3 = K_2CrO_4,CrO_3$), 1863. Potassium dichromate ($K_2O.2CrO_3$), 1872.
24. Dichromate de potasse.
25. Saures chromsaures Kali.
26. Potassium bichromate or anhydrochromate ($2CrO_3,K_2O$, or CrO_4K_2, CrO_3).
27. Potassic dichromate ($K_2Cr_2O_7$).
28. Bichromate de potasse ($K_2O,2CrO_3$).
29. Bichromate of potash ($K_2O,2CrO_3$).
30. Kalium dichromat.
31. (Neutrales) Dichromsaures Kali. $\left(O\begin{cases}CrO_2OK\\CrO_2OK\end{cases}\right)$.
32. Potassium bichromate or anhydrochromate ($2CrO_3,K_2O$, or CrO_4K_2, CrO_3).
33. Potassic dichromate, pyrochromate, or anhydrochromate ($K_2O,2CrO_3$, or $K_2Cr_2O_7$).
34. Potassium dichromate, or bichromate of potash ($K_2Cr_2O_7$).
35. Dipotassic dichromate $\left(\begin{cases}CrO_2Ko\\O\\CrO_2Ko\end{cases}\right)$
36. Potassium dichromate.

16. Bichromate of chloride of potassium ($KCl+2CrO_3$).
17. Bichrômate de chlorure de potassium, or chlorochrômate de potasse ($KCl.2CrO^3$).
18. —
19. Zweifach chromsaures Chlorkalium ($KaCl,2CrO_3$).
20. Bichromate of chloride of potassium ($KCl,2CrO_3$).
21. Bichrômate de chlorure de potassium, or chlorochrômate de potasse.
22. —
23. Chromochloride of potassium, 1863. Potassium chromatochloride, 1872. Potassium chlorochromate, 1875 and 1879 (KCl,CrO_3).
24. —
25. —
26. —
27. —
28. Bichromate de chlorure de potassium.
29. —
30. —
31. Chlorchromsaures Kali $\left(CrO_2{}^{Cl}_{OK}\right)$.
32. —
33. Dichromate of chloride of potassium, or potassic chlorochromate (KCl, CrO_3 ?).
34. Potassium chlorochromate ($KCrO_3Cl$).
35. —
36. Potassium chlorchromate.

VIII.

1. Nitrat of lead.
2. Nitrate of lead.
3. Subnitrate of lead.
4. Subnitrate of lead.
5. Dinitrate of lead.
6. Dinitrate of lead ($2PL+n'$).
7. Nitras biplumbicus ($Pb^2\dddot{N}_2$).

8. Dinitrate of lead ((2PL + n′).
9. Bibasic nitrate of lead ($PbO,NO_5 + PbO$).
10. —
11. —
12. Basisch salpetersaures Bleioxyd ($\dot{P}b\ddot{\ddot{N}}$).
13. Zweifach basisch salpetersaures Bleioxyd ($2PbO,\cancel{N}O_5$, or $2PbO,\cancel{N}O_5.\cancel{H}O$).
14. —
15. Basic salt, containing two atoms of oxide of lead united to one of nitric acid.
16. Bibasic nitrate of lead ($PbO,NO_5 + PbO$).
17. Sous-azotate de plomb; azotate bibasique ($2PbO.NO^5 + HO$).
18. Basic nitrate.
19. Halbsaures Salz (PbO,HO,PbO,NO_5).
20. Dinitrate of lead ($2PbO,NO_5$).
21. (See 17).
22. —
23. Basic nitrates of lead; diplumbic nitrate.
24. Azotate basique de plomb $\left(\cancel{Pb}''\begin{cases}\Theta Az\Theta_2\\ \Theta H\end{cases}\right)$.
25. —
26. Basic nitrate.
27. Plumbic hydronitrate ($PbNO_3HO$).
28. Azotate diplombique $(AzO_3)_2Pb,PbO$ or parazotate, $(Az_2O_7)Pb_2$, or orthoazotate $(AzO_4)'''Pb''\bar{H}$.
29. —
30. Halbgesättigt hydratisch basisch Salpetersauresblei.
31. Basisches Salz $\left(\begin{matrix}NO_2\\H\end{matrix}\right\}O_2Pb\Big)$.
32. Basic nitrate.
33. Dibasic plumbic nitrate ($Pb2NO_3, PbH_2O_2$).
34. Basic nitrate, $Pb(NO_3)OH$.
35. Plumbic nitrate hydrate, $NO_2(OPb''Ho)$.
36. Basic salt.

IX.

1. Submuriat of lead.
2. Submuriate of lead.
3. Submuriate of lead.
4. —
5. —
6. —
7. —
8. Oxychloride of lead.
9. Bibasic chloride of lead ($PbCl + 2PbO$), Tribasic ($PbCl + 3PbO$).
10. —
11. —
12. —
13. Einfach-, zweifach-, &c. basisches Chlorblei ($PbCl + PbO$), &c.
14. —
15. —
16. Oxychloride of lead.
17. Oxychlorure.
18. —
19. Basische Bleichloride, Oxychlorid, Bisoxychlorid, &c. ($PbO,PbCl, 2PbO,PbCl$, &c.)
20. Oxychlorides of lead ($PbO,PbCl$, &c.)
21. Oxychlorure.
22. —
23. Oxychlorides (Pb_2Cl_2O or $PbCl_2PbO$, &c.), 1881, III. Supp.
24. Oxychlorures de plomb.
25. —
26. Oxychlorides $PbCl_2,PbO$, &c.)
27. Basic plumbic chlorides ($Pb_2OCl_2, Pb_3O_2Cl_2$, &c.)
28. —
29. Oxychlorides of lead ($PbCl_2,PbO$, &c.)
30. Diplumboxydchlorür; Triplumbdioxydchlorür, &c.
31. Basische Salze.
32. Oxychlorides ($PbCl_2,PbO$, &c.)
33. Oxychlorides of lead ($PbO,PbCl_2$, &c.)
34. Basic chlorides ($PbCl_2 + PbO$, &c.)
35. Oxychlorides.
36. Oxy- or basic chloride.

X.

1. —
2. Subnitrate of bismuth.
3. Subnitrate of bismuth.
4. —
5. Tetartonitrate of bismuth.
6. Hydrated subnitrate of bismuth.
7. —
8. Hydrated subnitrate of bismuth.
9. Subnitrate of bismuth ($HO,NO_5 + 3BiO$).
10. Salpetersaures Wismuthoxyd, einfach. Basisch salpetersaures Wismuthoxyd ($BiO_3,NO_5 + Aq$).
11. Basisch salpetersaures Wismuthoxyd; Bismuthum Subnitricum ($N_2O_5,BiO + 3BiO,Aq.N_2O_5,BiO + 2BiO$).
12. Verbindung von salpetersaurem Wismuthoxyd mit Wismuthoxydhydrat ($Bi\ddot{\ddot{N}} + 3\dot{B}i\dot{\cancel{H}}$).

13. Basisch salpetersaures Wismuthoxyd, drittelsaures salpetersaures Wismuthoxyd.
14. Basisch salpetersaures Wismuth.
15. A basic salt $(BiO_3 + NO_5)$.
16. Subnitrate of bismuth $(BiO_3,NO_5 + HO)$.
17. Sous-azotate de bismuth.
18. Basic nitrate of teroxide of bismuth $(BiO_3,NO_5 + 2HO)$.
19. Drittelsaures Salz $(BiO_3,NO_5 + 2HO)$, Bisoxynitrat $(2(BiO_3,3HO)BiO_3,3NO_5)$.
20. Subnitrate of bismuth $(9HO,4NO_5, + 5BiO_3)$.
21. Sous-azotate de bismuth.
22. —
23. A basic nitrate $(BiNO_4,H_2O$ or $Bi_2O_3,N_2O_5,2H_2O)$.
24. Sous-azotate.
25. —
26. Basic nitrate $(Bi_2O_3,N_2O_5,2OH_2$, or $Bi''(NO_3)_3,Bi_2O_3,3OH_2)$.
27. —
28. Azotate basique de bismuth $(Bi'''(AzO_4) + H_2O$ or $(BiO)AzO_3 + H_2O)$.
29. Basic nitrate of bismuth, also called trisnitrate of bismuth (Bi_2O_3, N_2O_5,H_2O).
30. Wismuthnitrat. $Bi(ONO_2)(OH)_2$.
31. Basisches salpetersaures Wismuthoxyd $\left(\begin{matrix}N & \\ & H_2^2\end{matrix}\right\}O_3Bi$ or $NO_2OBiO + H_2O)$.
32. Basic nitrate (see 26).
33. Bismuthous subnitrate $(Bi_2O_3, 2HNO_3)$.
34. Basic bismuth nitrate, $Bi(OH)_2NO_3$.
35. Bismuthous nitrate dihydrate, $NO_2(Bi''Ho_2O)$.
36. Basic bismuth nitrate, $Bi(OH)_2NO_3$.

XI.

1. —
2. —
3. —
4. —
5. A subsalt.
6. A compound of oxide of bismuth with chloride.
7. —
8. (See 6.)
9. A subsalt $(BiCl + 2\,BiO + HO)$
10. Wismuthoxyd-chlorwismuth. Wismuthoxychlorür. Basisch salzsaures Wismuthoxyd $(BiCl_3, 2BiO_3)$.
11. Basisches Salz.
12. $(BiCl + 2\dot{B}i\dot{\cancel{H}})$.
13. Wismuth Bisoxychlorid. Zweifachbasisches Wismuth Chlorid $(Bi_2\cancel{Cl}O_2$ oder $Bi_2\cancel{Cl}_3 + Bi_2O_3)$.
14. —
15. Oxychloride of bismuth $(BiCl_3 + 2BiO_3 + 3HO)$.
16. Oxychloride of bismuth $(BiCl_3, 2BiO_3)$.
17. Oxychlorure de bismuth $(Bi_2Cl_3 + 2(Bi_2O_3 + 3HO)$.
18. —
19. Bisoxychlorid, zweifach basisches Salz $(2BiO_3,BiCl_3)$.
20. Oxychloride of bismuth $(BiCl_3, 2BiO_3)$.
21 (See 17.)
22 —
23. Oxychloride of bismuth $(BiOCl)$, 1863. Bismuthyl chloride $(BiOCl)$, 1879. Supp. III.
24. Oxychlorure $(BiOCl)$.
25. Basisches Chlorwismuth.
26. Oxychloride $(BiClO)$.
27. Bismuth oxychloride $(BiOCl)$.
28. Oxychlorure de bismuth $(BiOCl$ or $Bi_2O_3,BiCl_3)$.
29. Oxychloride of bismuth, $2(BiCl_3, Bi_2O_3),H_2O$.
30. Wismuthoxychlorür.
31. Basisches Chlorwismuth, Wismuthoxychlorid $(BiOCl)$.
32. Oxychloride $(BiClO)$.
33. Bismuthous oxychloride, $2(BiCl_3 Bi_2O_3),OH_2$ or $BiOCl$.
34. Bismuth oxychloride $(BiOCl)$.
35. Bismuthous oxychloride $(BiOCl)$.
36. Basic bismuth chloride. (Bismuth oxychloride.)

XII.

1. Oxysulphat of mercury.
2. Suboxysulphate of mercury.
3. Neutral persulphate of mercury.
4. Suboxysulphate of mercury.
5. Disulphate of mercury.
6. A sub-salt.
7. —
8. A sub-salt.
9. $(HgO.SO_3 + 2HgO)$.
10. Schwefelsaures Quecksilberoxyd, Drittel $(3HgO.SO_3)$.
11. Basisches schwefelsaures Quecksilberoxyd $(3HgO.SO_3)$.
12. Basisches schwefelsaures Quecksilberoxyd.
13. Basisch schwefelsaures Quecksilberoxyd $(3HgO.SO_3)$.
14. Basisches schwefelsaures Quecksilberoxyd.
15. Basic sulphate $(3HgO + SO_3)$.
16. Sub-sulphate.
17. Sel basique $(3HgO.SO^3)$.

18. A basic salt ($3HgO.SO_3$).
19. Drittelsaures Salz ($3HgO.SO_3$).
20. A sub-salt ($3HgO.SO_3$).
21. Sel basique ($3HgO.SO^3$).
22. —
23. Basic sulphate of mercury ($3HgO.SO_3 = HgSO_4.2HgO$).
24. Sel basique $\left.\left(\left.\begin{matrix}\mathrm{S\Theta}^{2''}\\ \mathrm{Hg}\\ \mathrm{Hg}\\ \mathrm{Hg}\end{matrix}\right\}\begin{matrix}\Theta\\ \Theta\end{matrix}\right)''\right\}\Theta^2$
25. —
26. A basic salt ($3HgO.SO_3$).
27. A basic salt (Hg_3SO_6).
28. Sulfate trimercurique($SO_4Hg,2HgO$).
29. A basic sulphate ($HgO.SO_3.2HgO$).
30. Drittelgesättigtes Mercuridsulfat.
31. Basisches Salz ($SO_2O_2Hg + 2HgO$).
32. A basic salt ($3HgO.SO_3$).
33. A basic salt ($HgSO_4.2HgO$).
34. A basic salt (Hg_3SO_6).
35. Trimercuric sulphate ($\mathrm{SH\overset{''}{g}o_3}$).
36. Basic sulphate ($SO_2.O_2Hg + 2HgO$).

11. Fluorsiliciumkalium. Kieselfluorkalium ($3KF_2,2SiF_6$).
12. Fluorkiesel Kalium.
13. Kalium-Kieselfluorid ($3KF,2SiF_3$).
14. —
15. Fluosilicate of potassium, silicofluoride of potassium ($SiF_2 + KF$).
16. Double fluoride of silicon and potassium ($2SiF_3,3KF$).
17. Hydrofluosilicate de potasse ($3KFl, 2SiFl_3$).
18. Double fluoride of silicium and potassium ($3KF,SiF_3$).
19. Kieselfluorkalium. Fluorkieselkalium ($3KaFl,2SiFl_3$, oder $KaFl,SiFl_2$).
20. Silicofluoride of potassium (KF, SiF_2).
21. Hydrofluosilicate de potasse ($3KFl, 2SiFl_3$).
22. —
23. Silicofluoride of potassium. Potassic silicofluoride ($2KF,SiF_4$).
24. Fluorure double de silicium et de potassium.
25. Kieselfluorkalium.
26. Double fluoride of silicium and potassium ($2KF,SiF_4$).
27. Potassic fluosilicate (K_2SiF_6).
28. Fluosilicate de potassium.
29. Silicofluoride of potassium ($2KF, SiF_4$).
30. Metallsilicofluorüre.
31. Kieselfluormetalle (SiF_4,MF_2).
32. Double fluoride of silicium and potassium ($2KF,SiF_4$).
33. Potassic silicofluoride.
34. Silicofluoride. potassium fluosilicate (K_2SiF_6).
35. Potassic silicofluoride ($SiF_6K_2 = Si F_4,2KF$).
36. Potassium fluosilicate.

XVI.

1. Muriat of platinum and potass.
2. Muriate of platinum and potash.
3. —
4. —
5. Bichloroplatinate of potassium.
6. Platino-bichloride of potassium ($(pl + 2c) + (po + c)$).
7. —
8. Platino-bichloride of potassium ($(pl + 2c) + (po + c)$).
9. Chloride of platinum and potassium ($KCl + PtCl_2$).
10. Zweifach Chlorplatinkalium ($KCl + PtCl_2$).
11. Kaliumplatinchlorid ($KCl_2 + PtCl_4$).
12. Kaliumplatinchlorid.
13. Kalium-platinchlorid ($KCl + PtCl_2$).
14. Platinchlorid-chlorkalium.
15. Double salt of bichloride of platinum with chloride of potassium ($KCl + PtCl_2$).
16. Chloroplatinate of potassium ($KCl, PtCl_2$).
17. Chlorure double de platine et de potassium ($PtCl_2 + KCl$).
18. Bichloride of platinum and chloride of potassium ($PtCl_2,KCl$).
19. Kalium-platinchlorid. Kalium-chloroplatinat ($KaCl,PtCl_2$).
20. Double chloride of platinum and potassium ($KCl,PtCl_2$).
21. Chlorure double de platine et de potassium ($PtCl_2 + KCl$).
22. —
23. Chloroplatinate of potassium, 1866. potassium platinochloride ($K_2Pt Cl_6$). Supp. I. 1872.
24. Chlorure double de platine et de potassium.
25. Kaliumplatinchlorid.
26. Potassium platinochloride ($2KCl, PtCl_4$).
27. —
28. Chloroplatinate de potassium.
29. Platinochloride of potassium ($2KCl, PtCl_4$).
30. Kaliumplatinchlorid.

Report of the Committee, consisting of Professors ODLING, HUNTINGTON, *and* HARTLEY, *appointed to investigate by means of Photography the Ultra-Violet Spark Spectra emitted by Metallic Elements, and their combinations under varying conditions. Drawn up by* Professor W. N. HARTLEY, *F.R.S.* (*Secretary.*)

THE last Report of this Committee was presented at the Southport meeting of the British Association; since then an investigation in detail has been prosecuted of the changes observable in photographs of the spectra of the metals when a series of solutions of definite strengths is examined. It had previously been shown that solutions containing the same element in different proportions emit variations of the same spectrum, the lines differing in number, length, and intensity; and the converse—namely, that under the same spark conditions similar solutions of the same strength always emit the same spectrum. Furthermore, I have shown the invariable character of the cadmium, tin, lead, and magnesium lines by observations made on about five thousand photographs, including not fewer than two hundred examples of other metals. The reason of this arises from the fact that unless the spark be almost at the highest temperature attainable, its emissive power is insufficient to affect the photographic plate in the usual period of exposure; it follows from this that when a condenser of constant capacity is in circuit, variable conditions such as may be introduced by the electrodes being near together or far apart, or by the use of a large or small coil, do not affect the result. Sparks are shortened and the character of the spectra is greatly altered by the use of a coil with a stout secondary wire, an instrument introduced and employed by M. Eugène Demarçay. The use of an instrument of this kind is not well adapted to the photographic method of working, because the nature of the sparks is such that the graphite electrodes are rapidly burnt away and the sparks are very short.

For the examination of solutions chlorides are generally employed, but sulphates and nitrates are also used. The electrodes are nearly always of graphite ('Phil. Trans.' p. 52, Part I. 1884); sometimes gold, copper, or platinum electrodes are required for special purposes, wires of the metal being twisted into wicks.

The solutions examined generally contained 1 per cent., $\frac{1}{10}$th, $\frac{1}{100}$th, and $\frac{1}{1000}$th of metal. It is seldom that more than three or four lines are visible in solutions of the latter dilution, and the rapidly diminishing number of lines in solutions weaker than $\frac{1}{10}$th per cent. is very striking. In the following tables the spectra corresponding to various solutions are given, and attention is particularly directed to the copper, silver, and tin spectra as illustrating this point. In many spectra it is impossible to predict the line or lines which will be found to be the most persistent. It is also noticeable that the alteration of lines consequent on the dilution of solutions is variable in character with different lines in the same spectrum. Generally speaking, long lines shorten until they disappear, sometimes they become attenuated before they shorten, and in other cases they attenuate until they fade away altogether.

The calcium lines H and K attenuate considerably before they shorten, while the lines of copper with wave-lengths 3273·2 and 3246·9, and of silver, 3382·3 and 3280·1, attenuate and fade almost away before shortening.

Several examples could be quoted of the analysis of minerals made by the spectroscope, the metallic constituents being estimated quantitatively with exactitude and great facility. In some cases the results obtained by the spectroscope inspire greater confidence than those made by ordinary methods.

The descriptive tables which follow are intended to be used with maps drawn to the scale of wave-lengths, and to a scale of actual measurements taken from photographs, so that the lines may be readily identified. The scale numbers given in the tables in hundredths of an inch refer to photographs such as those published in the 'Journal of the Chemical Society' ('Trans.' vol. xli. p. 90, 1882), from which actual measurements may be taken with an ivory scale.

The limit of sensitiveness of the spectrum reaction is perhaps the greatest in the case of magnesium; one part of the metal in 10,000 millions of solution is easily detected by the appearance of the lines with wave-lengths 2801·6 and 2794·1 attenuated and shortened. By increasing the strength of the spark the sensitiveness may be magnified 10,000 fold.

It was shown in the Report presented in 1883 how spectrum observations may be applied to determining the atomic weight of an element. Taking into account the spectrum of beryllium, this metal could find no place among the triad elements, but naturally took a position at the head of the dyad group. According to the periodic law its atomic weight would thus have the value 9. This view was opposed at the time, but it is satisfactory to learn that it has since been completely confirmed by the experimental work of Messrs. Nilson and Petterson and Dr. Humpidge.

309·6	2370·2			
309·94	2367·2			
310·62	2364·5			

The line with wave-length 3584·4 is both *much longer* and *stronger* than either 3612·6 or 3601·2, yet it is not so persistent. From appearing as a strong line it disappears rather suddenly.

The line with wave-length 2815·3 is the strongest in this spectrum.

Tabular Description of the Spectra characteristic of Solutions containing Magnesium.

Report of the Committee, consisting of Professor TILDEN, Professor W. RAMSAY, *and* Dr. W. W. J. NICOL (*Secretary*), *appointed for the purpose of investigating the subject of Vapour Pressures and Refractive Indices of Salt Solutions.*

I. *Molecular Volumes of Salt Solutions. Part II.*[1]

THE molecular volumes have been determined of fifty-six solutions, comprising forty-seven salts of potassium, sodium, lithium, strontium, cadmium, cobalt, and nickel, with chlorine, bromine, chloric, carbonic, sulphuric, nitric, orthophosphoric, metaphosphoric, acetic, oxalic, tartaric,

[1] Published in *Phil. Mag.*, 1884.

and citric acids. The previous results were completely confirmed. The law is as follows :—

The molecular volume of a salt in dilute solution is a quantity composed of two constants, one for the metal and another for the salt radical. It follows that the replacement of one metal, or salt radical, by another metal, or salt radical, is always attended by the same volume charge, no matter how they may be combined together.

The presence or absence of *water of crystallization* in one or both of the salts has no effect on the above law; it therefore follows that it has the same volume as the solvent water. *Water of constitution*, however, shows itself in solution by possessing a volume markedly different from that of the rest of the water.

These results point to the presence in solution of what may be termed the anhydrous salt, in contradistinction to the view that a hydrate, definite or indefinite, results from solution; or, in other words, no part of the water in solution is in a position, relative to the salt, different from the remainder.

II. *Saturation of Salt Solutions. Part II.*

It is found that the molecular volumes of a series of solutions of different strengths of the same salt may be satisfactorily expressed by the formula :—

$$\text{M. V.} = 1800 + n\alpha + n^2\beta - n^3\gamma.$$

Where n = number of molecules of salt per 100 H_2O, and α, β, and γ constants depending on the salt,

$$r = n\alpha + n^2\beta - n^3\gamma;$$

and

$$\frac{r}{n} = \alpha + n\beta - n^2\gamma.$$

This last is the mean molecular volume of the salt in solution. The curve is a parabola, and is such that $\frac{\beta}{\gamma} =$ twice the solubility of the salt in question $\therefore \frac{\beta}{2\gamma} =$ solubility; but this is also the apex of the parabola; saturation is therefore reached when the further addition of salt would produce diminution of the mean molecular volume of the molecules already present. The last molecule before saturation, enters into solution with a volume sensibly equal to the mean, as is shown thus :—

$$(n\alpha + n^2\beta - n^3\gamma) - ((n-1)\alpha + (n-1)^2\beta - (n-1)^3\gamma) = \alpha + n\beta - n^2\gamma.$$

$$\text{When } n = \frac{\beta + \gamma}{2\gamma}.$$

III. *Supersaturation of Salt Solutions.*[1]

In these papers experiments are described which lead to the conclusion that the only truly supersaturated solutions are those which result from the fact that, when a hot solution is cooled, a finite time is required for the excess of salt to crystallize out—what is usually

[1] Published (1) *Phil. Mag.*, June, 1885; (2) *Phil. Mag.*, September, 1885.

termed supersaturation is not really so at all. Thus a distinctly supersaturated solution of sodium sulphate readily dissolves a quantity of the dehydrated salt when brought in contact with it without access of air. This shows that the solution is not even saturated, much less supersaturated; still this may be explained by the supposition that the constitution of a supersaturated solution is not the same as an ordinary one, inasmuch as heat is necessary for its preparation; the effect of heat being to decompose the decahydrate, no union of water and salt taking place in cooling. In the second paper it is shown that this is entirely a mistake. Supersaturated solutions are readily prepared in the *cold* by simply enclosing the dehydrated salt in a bulb, placing this in a bottle with the proper quantity of water, and, after closing, heating the bottle to 100° for a few minutes. When the whole is *cold*, the bottle is shaken, the bulb broken, and the salt readily dissolves. If excess of salt be used, the solution has the same percentage composition as one prepared by heating the decahydrate, and allowing it to cool with the excess of salt to the same temperature, air being excluded. It is further found that when the dehydrated salt is brought in contact with the water, as above described, no caking together is observable, the powdery condition being retained till solution is complete. Thus there is no hydration previous to solution, as is indeed shown by the possibility of preparing supersaturated solutions in this way, for were the smallest trace of the decahydrate produced such a solution, could not be formed. During the act of solution, however, considerable heat is evolved, which, as shown above, cannot be due to hydration, but may possibly result from the enormous contraction, about 40 per cent., undergone by the salt.

Finally, density determinations of solutions of Na_2SO_4 and $Na_2S_2O_3$, of various strengths, show that in passing the ordinary saturation point there is nothing to indicate any change in the constitution of the solution. The molecular volume steadily increases from the most dilute solution up to the most concentrated supersaturated solution examined, exactly as it does with an ordinary solution which is not capable of supersaturation.

From these and other experiments it follows that a so-called supersaturated solution is simply a saturated or non-saturated solution of the anhydrous salt; that any solution of a hydrated salt contains no hydrate of that salt, but that it is at the moment of crystallization that combination of the water and salt takes place.

IV. *Vapour Pressures of Salt Solutions.* 1. *Boiling Points of Saturated Solutions.*[1]

The method of experiment was to measure the pressure under which a saturated solution of the salt boiled at a definite temperature. The experiments included determinations at 65°, 75°, 85°, and 95° for $NaNO_3$, KNO_3, Na_2CO_3, K_2CO_3, $MnSO_4$, $FeSO_4$, and the results are expressed in terms of degrees of rise of boiling point. This is found to be a quantity increasing with the temperature when the solubility increases; on the other hand, it decreases when the solubility diminishes with rise of temperature.

It is preferable, however, to express the effect of salt on the

[1] Published *Phil. Mag.*, October 1885.

vapour pressure of water by the value $\frac{1-p^1}{pn}$; where p = pressure of vapour of pure water, p^1 = pressure of water vapour from salt solution containing n molecules per 100 H_2O, and this, as was to be expected, is in all cases a diminishing quantity with rise of temperature—showing that, in a constantly saturated solution, a salt exercises a less restraining effect on the water the higher the temperature.

2. *Vapour Pressure of Water from Non-saturated Salt Solutions.*

The experiments on this subject are not yet complete, but are sufficiently advanced to justify certain conclusions regarding the behaviour of salts under varying conditions of temperature and concentration.

The method employed was the same as that in the previous section, with this difference, that a dilute, not a saturated, solution of the salt was employed, and successive portions of water were distilled off and weighed. In this way the concentration at different pressures and at a definite temperature was readily determined.

Four salts have, as yet, been examined, NaCl, KCl, $NaNO_3$, and KNO_3. The temperature chosen was 70°, though some experiments were made at 90°.

Two of the above salts have been examined in solutions of constant strength at temperatures of 70°, 75°, 80°, 85°, and 90°.

The general results are as follows:—

(α) When temperature is constant and n varying, then $\frac{p-p}{n}$ increases with increase of n in the case of NaCl; is constant, or nearly so, with KCl, and diminishes more or less rapidly with $NaNO_3$ and KNO_3. These results are fully confirmed by Tammann's results, obtained by the Barometric method (Wiedem. *Ann.* 24), a close agreement being found between the two sets of figures.

(β) When the concentration is constant but temperature varying, then the value of $\frac{p-p^1}{pn}$ or $1-\frac{p^1}{pn}$ is a diminishing one with NaCl and a slowly increasing one in the case of the other three salts. This also is confirmed by Tammann's results, and general agreement is to be found with the experiments of Legrand (1835), conducted in an entirely different way.

It is believed that there is an intimate connection between this behaviour of the salts and their solubility, but the discussion of this question is postponed till the results are more numerous and complete.

V. *Expansion of Salt Solutions.*

The dilatation of solutions containing definite numbers of molecules, 1, 3, 5, or 2, 4, 6, &c., of NaCl, KCl, $NaNO_3$, and KNO_3, have been determined by means of specially constructed dilatometers, and a special constant temperature bath, by means of which a tube 700mm. long can be kept for any length of time at a definite temperature, the temperature of the one end differing from that of the other not more than 0°·1. Thus all necessity for correction of the results for the exposed portion of the stem of the dilatometer is avoided.

As in the previous section, the experiments are not yet complete, but have fully established the following conclusions:—

(α) The expansion of a salt solution is the more uniform the more concentrated it is. The curves representing the expansion approach more nearly straight lines as n increases.

(β) At low temperatures salt solutions expand more than water, at higher ones less; there is thus a point at which the coefficient of expansion is the same as that of water. This temperature is little, if at all, affected by the concentration. They are as follows:—

NaCl . .	55°– 60°
KCl . .	50°– 55°
$NaNO_3$ . .	80°–100°
KNO_3 . .	75°– 80°

(γ) The volumes at different temperatures may be satisfactorily expressed by interpolation formulæ of the form

$$V=100{,}000+t'\alpha+t'^2\beta\,;$$

Where $t'=t°-20°$, and α and β constants depending on the salt and the value of n. In 126 determinations only two differed from the calculated value by more than $\frac{\pm 5}{100{,}000}$, the mean error being less than $\frac{\pm 2}{100{,}000}$. The constants α and β are thus related; as n increases α increases, but β decreases; the expansion approximating more and more to $100{,}000+\alpha\, t'$.

The results confirm in most points those of Kremers, and it is hoped when the experiments are complete that it will be possible to establish the connection between the vapour pressures and the molecular volumes, as has already been attempted by Tammann in an incomplete form.

Report of the Committee, consisting of Professor Sir H. E. ROSCOE, Mr. J. N. LOCKYER, Professors DEWAR, WOLCOTT GIBBS, LIVEING, SCHUSTER, *and* W. N. HARTLEY, Captain ABNEY, *and* Dr. MARSHALL WATTS (*Secretary*), *appointed for the purpose of preparing a new series of Wave-length Tables of the Spectra of the Elements and Compounds.*

THE present Report contains the completion of the tables of the spectra of the elements, and a portion of those of the spectra of compounds. The measurements are given in ten-millionths of a millimetre (or tenth-metres), and are based upon the measurements of the Fraunhofer lines by Ångström for the whole visible rays, and the extension of the same series of measurements into the ultra-violet portion of the spectrum made by Cornu and other observers. It will be well to repeat here the fundamental values of wave-length of the chief solar lines. The small corrections indicated at page 29 of Ångström's Memoir, 'Le Spectre Normal du Soleil,' have been applied to his numbers—but they are uncorrected for the dispersion of air. Hence the numbers in the tables represent wave-lengths in air of 760mm pressure at Upsala, and 16° C. temperature. The numbers taken from Thalén's 'Détermination des Longueurs d'Onde des Raies Métalliques' in the same way have had applied to them the necessary small corrections to bring them into harmony with the numbers finally adopted by Ångström as 'Valeurs définitives' (pp. 25 and 31–32).

FRAUNHOFER LINES

A		7604·0

S_1	(Ni, double)	3100·6	} 3100·0
S_2	(Fe, triple)	3099·5	
s	(Fe)	3046·4	
T	(Fe, double)	3019·7	
t	(Fe)	2994·3	
U	(Fe)	2947·8	

The following symbols are employed in the tables to indicate the character of the lines :

s denotes that the line is sharply defined.
n denotes that the line is ill-defined or nebulous.
b denotes a band, the position of the brightest part being given.
b^r denotes a band sharply defined on the least refracted side, and fading away towards the blue.
b^v denotes a band sharply defined on its more refracted side, and fading away towards the red.

The width of a broad band is sometimes indicated by a *suffix*, giving the width in ninth-metres; thus, 4997 b^r_5 means that the bright edge of the band is the 4997, and that it fades away above 4947 ; whereas 6532 b_4 means that the band extends from 6552 to 6512, its brightest point being at 6532.

c denotes that the line is continuous.
d denotes that the line is discontinuous, or a 'short' line.
r denotes that the line is frequently 'reversed.'
A number within parentheses, thus : (3091·9), means that while a line in this position has been observed, no new measurements of wave-length was made —the wave-length being quoted from another observer.

The intensities of the lines are expressed upon an ascending scale from 1 to 10 ; 1 being the feeblest and 10 the brightest.

* Double.

The spark spectrum of ammonia, according to Lecoq de Boisbaudran, shows one broad band at 5657 (5656·5 Schuster) which, with a finer slit, is resolved into two bands, 5681 of intensity 7, and 5643 of intensity 8 (5686 to 5627 Schuster). Lecoq de Boisbaudran obtained the 'Flame Spectrum' also by use of the spark; its production appears to depend upon the presence of oxygen.

Thirteenth Report of the Committee, consisting of Professors J. PRESTWICH, W. BOYD DAWKINS, T. MCK. HUGHES, *and* T. G. BONNEY, DR. H. W. CROSSKEY (*Secretary*), DR. DEANE, *and* Messrs. C. E. DE RANCE, H. G. FORDHAM, J. E. LEE, D. MACKINTOSH, W. PENGELLY, J. PLANT, *and* R. H. TIDDEMAN, *appointed for the purpose of recording the position, height above the sea, lithological characters, size, and origin of the Erratic Blocks of England, Wales, and Ireland, reporting other matters of interest connected with the same, and taking measures for their preservation.*

THE Committee have to record the following additional observations. Continuing his previous investigations, Mr. Luff, of Clun (Shropshire) has traced fragments of the Upper Llandovery grit (which are scarcely large enough to be called 'boulders') along a bee line drawn across the map from Clun to Rhayader, twenty-three miles W.S.W. This line passed through Llanbister and Abbey-cwm-hir; crossed at right angles the deep valleys of the Teme and the Ithon, and passed over the extensive Beguildy Mountains and the long transverse range of Cambo Hill. Fragments of grit were found at short intervals the whole of the way,

and two miles south of Rhayader the rocks of Carrig Gwinion present themselves as the source from which they all may have been derived. The specimens were very small—the largest being about one foot cube—and in no respect equal the remarkable assemblage of big blocks, previously described, on the long and high ridge forming the watershed of the Clun and Teme. These fragments of grit, however, occur at considerable heights as well as in the valley bottoms—being found on the top of Beguildy Beacon, more than 1,700 feet above the sea. One block of Rhayader grit has been found north of the Clun river, but as a rule the Clun river forms a northern boundary to this flow in a peculiarly sharp and striking way. A remarkable mixture of boulders occurs. Amongst the western boulders on the Clun Hills are (although few in number) quartzites from the Stiper Stones district fifteen miles north, and about Leebotwood, north of the Longmynd, are granites from Scotland or the Lake district. The flow of quartzites has overlapped and invaded the ground covered by the Plynlimmon stream, and the granites while doing the same with this local dispersion, have crossed the eastern stream of Arenig boulders.

Professor Bonney writes that he is now satisfied, in consequence of information supplied to him by Professor Hughes, that the picrite boulders noticed by him in the Report for 1883 as occurring near the west coast of Anglesey, are derived from masses of rock which occur *in situ* to the north-east, especially from one near Caemawr. He has also received from Dr. H. Hicks specimens of a boulder of very characteristic hornblende picrite, which the latter found lying on 'Dimetian' rock, on the east side of Porthlisky harbour, near St. David's. Its longer axis measured about a yard: in transverse section it was rather triangular, the shorter sides measuring twenty-two inches and sixteen inches respectively. No rock of the kind is known to occur *in situ* anywhere in the district. This is more fully described, and the origin of the Anglesey boulders discussed in a paper by Professor Bonney which has appeared in the 'Quarterly Journal of the Geological Society' (vol. xli. p. 511).

Mr. R. T. Andrews of Hertford has forwarded the Committee a catalogue of blocks from that neighbourhood, showing that the materials generally spread over the north of Herts extend south to the Hertford district. These may be divided into three main groups. (1) Hertfordshire '*Pudding-stone*'; (2) Compact sandstones; (3) Grits and coarse sandstones. The Hertfordshire 'Pudding-stone' is of course locally derived. The fine compact sandstones, with coarser sandstones and grits, are of the kind so common in the boulders of Hertfordshire and the adjacent counties, which have been fully described in the Report of the Committee for 1881. Mr. Fordham remarks upon this catalogue, that the derivation of the rocks cannot be stated with exactness, since there is little about the materials, as found in moderate sized fragments, to identify them with particular beds; but their characteristics generally show that in all probability some of them have been derived from the secondary rocks of the Midlands, while others have come from the millstone grits and other older rocks further north. The absence of igneous rocks in this catalogue will be noted. As igneous rocks are rare in the north of Hertfordshire, their apparent absence in the centre of the county shows that there has been a gradual diminution of igneous material towards the south, while at length in the centre of Hertfordshire they are certainly absent.

Catalogue of Boulders found in the neighbourhood of Hertford.

No.	—	Dimensions	Where found	Remarks
1	Compact Sandstone . .	3′ 0″ × 2′ 6″ × 2′ 0″	Brickendon Green, S.W. of Hertford.	Oblong and flattish; rounded off at one end more than the other; smooth. Height above the sea about 350 ft.
2	Coarse Sandstone or Grit .	2′ 9″ × 2′ 2″ × 1′ 6″	Removed from adjacent field to N. of a barn at Clement's farm.	Smooth.
3	Compact Sandstone . .	1′ 6″ × 1′ 5″ × 1′ 4″	Angle of a pond; Clement's farm.	Height above sea, 230 ft.
4	Herts Pudding-stone .	Fragment	Brickendon Green.	Used for foundations of a shed.
5	,, ,,	,,	,,	,,
6	,, ,,	,,	,,	,,
7	,, ,,	,,	,,	,,
8	,, ,,	3′ 2″ × 2′ 1″ × 1′ 0″	,,	Smooth.
9	Herts Plum-pudding stone	2′ 7″ × 1′ 8″ × 1′ 5″	In garden, Castle Street, Hertford.	Probably removed from elsewhere in neighbourhood.
10	,, ,,	2′ 1″ × 1′ 2″ × 1′ 3″	Castle Street, Hertford. In fernery.	
11	,, ,,	1′ 4″ × 1′ 1″ × 9″	Bayford.	Brought to garden of lodge from a ploughed field.
12	,, ,,	1′ 6″ × 1′ 3″ × 1′ 0″	Tyler's Causeway; inside cottage-garden gate.	Brought from same field as No. 11.
13	,, ,,	2′ 3″ × 1′ 8″ × 9″	Hill going up to Tolmer's Church.	
14	,, ,,	2′ 3″ × 1′ 2′ × 1′ 0″	,,	
15	,, ,,	1′ 4″ × 1′ 2″ × 8″	,,	
16	Compact Sandstone . .	1′ 9″ × 1′ 6″ × 1′ 2″	Essendonbury farm; at entrance gate.	Very irregular in shape; taken from a neighbouring gravel pit.
17	Coarse Sandstone or Grit .	1′ 4″ × 11″ × 12″	Goose Green.	
18	Compact Sandstone . .	2′ 9″ × 1 9″ × 7″	Dalmond's farm; Mangrove Lane.	Taken out of a pond; from its regular thickness a doubtful specimen.
19	Herts Pudding-stone .	4′ 6″ × 3′ 3″ × 1′ 3″	Ibid., close to a fence adjoining farmhouse.	The finest of all the specimens.

CATALOGUE OF BOULDERS—*continued.*

o.	——	Dimensions	Where found	Remarks
0	Coarse Sandstone or Grit .	3′ 8″ × 1′ 11″ × 1′ 7″		
1	Compact Sandstone . .	1′ 3″ × 1′ 1″ × 8″	Jenningsbury farm.	Smooth faced; subangular; obtained from gravel pits.
22	Herts Pudding-stone .	3′ 0″ × 1′ 8″ × 2′ 0″	Stable-yard, 'Salisbury Arms,' Hoddesdon.	From the gravel pits; hard and tough.
23	Compact Sandstone . .	1′ 6″ × 1′ 3″ × 10″	From gravel pit, Roman road.	
24	Herts Pudding-stone .	11″ × 10″ × 7″	Ware Park Mill	
25	" "	2′ 7″ × 2′ 3″ × 1′ 4″	Ware.	From gravel pit, Park Road; found nearly at the surface.
26	Compact Sandstone . .	2′ 1″ × 1′ 5″ × 8″	Pepper Hill, Ware.	Such stones often found in this gravel pit; some of large dimensions; rather sharp angled, and smooth.
27	" "	1′ 4″ × 1 2″ × 10″	"	Smooth; subangular.
28	Coarse Sandstone or Grit .	2′ 8″ × 1′ 5″ × 1′ 3″	Amwell End, Ware.	Peculiarly ragged in shape, with rounded angles and indented.
29	" " "	2′ 2″ × 1′ 5″ × 1′	"	Flattish; subangular; appears as if split from a larger block.
30	Carboniferous Limestone ?	3″ × 1′ 7″ × 1′ 5″	Ware.	Taken out of water course; Angel Mead, Musley Lane.
31	Herts 'Pudding-stone' .	2′ 0″ × 2′ 0″ ×	Westmill Hill, Ware.	Smooth and subangular.
32	Coarse Sandstone or Grit .	2′ 0″ × 2′ 6″ × 1′ 4″	Opposite 'Rose and Crown,' Ware.	Smooth and subangular.
33	Compact Sandstone . .	1′ 10″ × 1′ 0″ × 1′	Hoddesdon.	Preserved in Bull Inn Yard.
34	" "	2′ 1″ × 1′ 4″ × 1′ 0″	Amwell.	Subangular; probably from gravel pit.
35	" "	1′ 7″ × 1′ 3″ × 7″	Amwell, Pepper Hill.	Rather sharp angled; from gravel pit.
36	" "	1′ 8″ × 1′ 6″ × 1′ 1″	Amwell.	Subangular; from adjoining gravel pit.
37	" "	1′ 6″ × 1′ 2″ × 1′ 3″	Ware.	From gravel pit.

Third Report of the Committee, consisting of Mr. R. ETHERIDGE, Dr. H. WOODWARD, *and* Professor T. RUPERT JONES (*Secretary*), *on the Fossil Phyllopoda of the Palæozoic Rocks.*

§ I. SUPPLEMENTARY.—1. Professor C. Lapworth enables us to make the following corrections in the Second Report, 'Brit. Assoc. Report for 1884':—(1) The horizon of *Discinocaris gigas* (p. 80) is the 'Llandovery, in the Birkhill Shales.' (2) '*D. Browniana* (p. 78) also comes from the

Llandovery stage;[1] in fact, all the British Silurian forms of *Discinocaris* come from the same general horizon—the Llandovery (Birkhill series).' (3) '*Aptychopsis Wilsoni* (p. 89) occurs in the Wenlock stage (Riccarton Beds).' (4) '*Aptychopsis glabra* (pp. 91 and 92) is from the Middle Silurian Buckholm Beds of the Gala Group, Meigle, Galashiels, Selkirkshire. Its horizon in Tipperary may be Middle, rather than Lower, Silurian.' (5) '*Peltocaris aptychoides* (p. 93) from Duff-Kinnel belongs to the Llandovery stage (Birkhill Shales).' (6) '*Peltocaris* sp. (p. 94) occurs at Whitehope (not Wasthope) Burn, in the Birkhill series.' With the exception of *Peltocaris Harknessi*, all the forms of *Aptychopsis* and *Peltocaris* known to Professor Lapworth are of either Llandovery or Lower-Wenlock age.

2. *Caryocaris Marrii.* Another specimen has been observed in the British Museum, No. '42162.' See First Report, 'Brit. Assoc. Report for 1883,' p. 222.

3. *Lingulocaris siliquiformis.* First Report, 1883, p. 223, lines 13 and 14 from the bottom, *read* Schistose Bala rock, and collected by J. P., March 14, 1868. A fragment (from Garth) has been also noted in the Museum of Practical Geology, IV $\frac{2}{4}$, 'Catal. Cambr. Sil. Foss. M.P.G.' 1878, p. 15. We find also another specimen of *Lingulocaris lingulæcomes* (from Garth) in the British Museum, No. '48001.' See First Report, 1883, p. 223.

4. A form near *Solenocaris*, Meek, is in the Mus. Pract. Geol. X $\frac{1}{27}$, 'Catal. Cambr. Sil. Foss.' 1878, p. 142. From Freshwater-East, Pembrokeshire, north side; Ludlow Beds.

5. *Orthotonella? Faberi*, E. O. Ulrich, 'Journ. Cincinnati Soc. Nat. Hist.' vol. v. (1882?), p. 117, pl. 5, figs. 7, *7a*, *7b*, has a Phyllopodiform aspect, somewhat like that of Meek's *Solenocaris*, and we therefore asked Mr. Ulrich to look at it again; and he obligingly replies that it may possibly be one of these bivalved crustaceans.

6. *Solenocaris solenoides*, Young, 1869, alluded to in our First Report, 'Brit. Assoc. Report' for 1883, pp. 217 and 223, as a conchiferoidal Phyllopod, has been further studied, good specimens having been kindly supplied by Mrs. Gray, of Edinburgh. It is carefully described and figured in the 'Geol. Mag.' for August 1885, p. 356, pl. IX, fig. 11; and, proving not to be a Phyllopod, is referred to *Helminthochiton* as *H. solenoides* (Young); and another species of the same genus has been found by Mrs. Gray at Thraive, near Girvan, and has been described with the former as *H. Grayiæ*, H. Woodward, figs. 7–10. The little 'oblong, obliquely ridged, and concentrically marked' bodies are moieties of the dorsal plates of *Helminthochiton*. A nearly perfect series of whole plates found by Mrs. Gray at Thraive, near Girvan, is figured and described in Dr. Woodward's memoir.

7. With reference to *Goniatites* having *Aptychi* or *Anaptychi*, and as to some of the so-called Phyllopodous shields being really such parts of *Goniatites*,[2] we have to state that, in confirmation of Herr Kayser's discovery of a '*Spathiocaris*' in the body-chamber of a Devonian Goniatite, we have now seen some similar examples from Bicken; and that we believe some of the so-called Phyllopodous shields which come from

[1] We notice that in the *Quart. Journ. Geol. Soc.* xxxvi. 1880, p. 617, Mr. Marr states that Herr Dusl has three specimens of *Discinocaris Browniana* from the strata of 'Colonie Haidinger,' in Bohemia (= Stage E e 1, according to Mr. Marr).

[2] See the Second Report, 1884, p. 76.

Goniatitiferous Devonian strata will have to be referred to *Goniatites*. Thus we must look with some doubt on the following Devonian forms :—

Discinocaris dubia (Roemer)	See Second Report, 1884, p. 79.
„ *lata* (Woodward)	„ „ „
„ *congener* (Clarke)	„ „ p. 80.
Spathiocaris Emersonii, Clarke	„ „ „
„ *ungulina*, Clarke	„ „ p. 81.
Pholadocaris Leeii, Woodward „ *sp.*	„ „ p. 82.
Ellipsocaris Dewalquei, Woodward „ *sp.*	„ „ p. 83.
Cardiocaris Roemeri, Woodward „ *bipartita*, Woodward „ *Veneris*, Woodward „ *Koeneni* (Clarke)	„ „ p. 84.
Dipterocaris pes-cervæ, Clarke „ *retusta* (D'Arch. and De Vern.) „ *procne*, Clarke	„ „ p. 85.

These, then, require further investigation ; but as numerous undoubted Phyllopoda, having structural features allied to those of the foregoing genera and species, occur in the Silurian strata that do not yield Goniatites, and as some even of the genera enumerated above are not always associated with Goniatites, there is no reason why members of the group should not occur even in Goniatitiferous strata. Thus some of the foregoing species may have no relationship with the Cephalopods among which they have been buried, but were lineal descendants of Silurian forms.

In his paper in the 'Neues Jahrbuch,' &c., 1884, Band i. p. 275, &c., 'On the Phyllopod-nature of *Spathiocaris*, *Aptychopsis*, and similar bodies,' met with in strata of Silurian, Devonian, and Carboniferous ages in Europe and North America, and described by M'Coy, Salter, Barrande, Meek, Hall, Clarke, ourselves, and others, after an elaborate criticism of the subject, Herr W. Dames concludes :—

1.—That some of the bodies in question are the *Aptychi* of *Goniatites*.

2.—That for others, this explanation is, according to our present knowledge, inadmissible.

3.—That the last are, however, in no case Phyllopods.

1.—As intimated above, we accept the first conclusion. The British Museum lately obtained several specimens of these *Aptychus*-like bodies,[1] from the black limestone of Bicken; and Mr. Robert Etheridge, jun., discovered among them a specimen of a small *Goniatites intumescens* with an imperfect *Aptychus in situ* in its mouth-aperture. This *Aptychus* seems to agree most nearly in form with the so-called '*Cardiocaris lata*,' from Budesheim in the Eifel,[2] also observed by Mr. J. M. Clarke at Bicken.[3] The other specimens of *Aptychus*-like bodies, not *in situ*, but from the same black Devonian limestone, agree *very closely* with Mr. Clarke's *Spathiocaris Koeneni*,[4] also from Bicken.

[1] We have also seen a specimen of *Aptychus* sent to Mr. John Edward Lee, of Torquay, by Professor Ferd. Roemer, of Breslau, and labelled '*Aptychopsis*, sp.= operculum of *Goniatites intumescens*, Upper Devonian, Bicken, near Herborn, Nassau,' in Dr. Roemer's own handwriting. Some of these specimens have been figured in the 'Geol. Mag.' dec. 3, vol. ii. pl. ix. figs. 1–6, in illustration of a paper (pp. 345–352) treating of this subject in full, and of the relationship of the fossil Phyllopods under notice to Nebalia.

[2] See 'Geol. Mag.' 1882, dec. 2, vol. ix. p. 388, pl. ix. fig. 13.

[3] 'Neues Jahrb.' &c. 1884, vol. i. p. 181, pl. iv. fig. 2.

[4] *Ibid.* fig. 1.

2.—Even after all those forms of supposed Phyllopod shields which occur in beds in which *Goniatites* have been found shall have been re-examined, we feel convinced, with Herr Dames, 'that for others, this explanation is, according to our present knowledge, inadmissible.'

The First and Second Reports drawn up by ourselves [1] on the PHYLLOPODA fully confirm Herr Dames' own conclusion that *all* the simple disc-like or bivalved shields met with in the older rocks cannot be regarded as the opercula of Cephalopods. There are indeed many special characters about these Palæozoic Phyllopod shields that will require to be carefully examined before they can all be referred to *Goniatites*. We would draw attention to the varied form of the notch; the absence in some, and the presence in others, of the dorsal suture; the presence in different genera of the rostral portion of the shield in the circular and oval forms, and the possible existence in some of a hinder trigonal shield-piece (*Pholadocaris*, *Dipterocaris*); the shape of the shield itself; the ornamentation; and, lastly, the substance composing it. Usually it is possible to discern the difference in character between Crustacean and Molluscan structures, as also between these and obscure Ichthyic fragments.

We note the following assertion in reference to the body-rings of *Discinocaris*: 'Even if the structures observed are really body-rings, no stronger proof against their phyllopod nature could be brought forward; for the body-rings, as well as all the other parts of the Phyllopod (except the shell), are *too tender and fragile* to remain recognizable in beds of such great age.' [2] (Dames, *op. cit.*)

In the presence of the long array of Insect-remains, of the most delicate and fragile characters, discovered in the Devonian and Carboniferous formations of North America, France, England, and elsewhere, this argument against the possibility of delicate organisms being preserved falls to the ground; whilst the relative thickness and durability of the calcareous or chitinous covering of the body-segments in these ancient Crustacea afford no proof for or against their Phyllopod nature, any more than does their relatively greater size when contrasted with existing Entomostraca. Moreover body-rings of *Ceratiocaris* are by no means rare in some Silurian strata.

3.—In the third conclusion, 'that even those forms which cannot be referred to *Aptychi* of Cephalopods, are in no case the shields of Phyllopods,' Herr Dames is simply stating a matter of opinion; for of their exact nature and true zoological position Claus himself (to whom he seems to refer) is not at all positive, whilst Dames admits that he has not examined the original specimens.

We have long held the opinion that the expanded disc-like shields, such as *Peltocaris*, *Discinocaris*, *Aptychopsis*, and some others, were pro-

[1] Also 'Geol. Mag.' 1883, dec. 2. vol. x. pp. 461–464; and 1884, dec. 3, vol. i. pp. 348–356.

[2] Professor A. von Koenen, replying to Herr Dames, on behalf of Mr. J. M. Clarke, very justly observes, 'I cannot see that this at all meets the argument, since the relative age of strata is of little influence on the preservation of fossils; on the other hand, there are plenty of examples in which fossil animals have been furnished with hard, horny, and even calcareous parts which are wanting in their nearest recent analogues. I will only recall here *Aptychus* and *Anaptychus*' ('N. Jahrbuch,' &c. 1884, Bd. ii. p. 45). The recent *Nautilus* has a fleshy hood; the fossil Ammonite had usually a hard calcareous *operculum*, but in some Liassic forms the operculum was *horny*.

bably related ancestrally to the larval or adult forms of Phyllopods like *Apus*, *Lepidurus*, &c. whilst the relationship between the living *Nebalia* and the numerous genera of Palæozoic Pod-shrimps does not necessarily preclude us from considering these forms as still belonging to the ENTOMOSTRACA, although placed in Packard's order PHYLLOCARIDA.

As to the question of ornamentation, upon which Herr Dames insists so strongly, the concentric striæ, marking lines of growth, appear to correspond most closely in character and origin with the similar decoration observable on the valves of *Estheria*, *Limnadia*, &c. so that their absence upon the carapaces of *Apus* and *Nebalia* does not necessarily prove that shields so ornamented cannot be deemed to belong to Crustacea or even to the PHYLLOPODA; whilst many of the carapaces of the fossil genera, e.g. *Dithyrocaris*, *Ceratiocaris*, &c. have either concentric or anastomosing striæ covering the entire surface of their carapaces; yet Herr Dames has evidently no doubt that these forms are related to *Nebalia*, which has a smooth carapace destitute of ornamentation.

He reminds us that Claus and Gerstaeker are of opinion that *Nebalia* is not a *Phyllopod*. Because *Nebalia* during its embryonal life (whilst still in the egg) passes through the 'Nauplius-' and 'Zoëa-stages,' which in Decapods occur partly in the free state, it has been regarded by some as a 'Phyllopodiform-Decapod.' The *potentiality* of a form to attain to a higher existence seems to be here mistaken for *actuality*. Since it never attains a higher development as an adult than that of a Phyllopod, and has no retrograde metamorphosis, may we not with as equal reason regard *Nebalia* as a highly-organised *Phyllopod*, as to assert that it is a Decapod arrested at the Phyllopod stage?

All who have studied the PHYLLOPODA have been struck by the peculiar points of special interest to be observed in *Nebalia*.[1]

Milne-Edwards, in his 'Histoire Naturelle des Crustacés' (1840), places *Nebalia* in the family *Apusidæ* among the Phyllopods; at the same time he remarks, 'The *Nebaliæ* are very singular little crustaceans, which, by reason of their stalked eyes [2] and their carapace, approach the PODOPHTHALMIA; they do not, however, possess branchiæ, properly so called, but they respire by the aid of their thoracic feet, which are developed into membranaceous and foliaceous appendages. They resemble in many respects, and establish a passage between *Mysis* and *Apus*.'

Baird (1850) founded the family *Nebaliadæ*, and regarded *Nebalia* as a Phyllopod.

Prof. J. D. Dana (1853), in his great work on the Crustacea, retained the family name (*Nebaliadæ*), which he placed in the PHYLLOPODA.

Metschnikoff in 1865 published an abstract of his account of the development of *Nebalia Geoffroyi*, and in 1868 the full essay in the Russian language. Fritz Müller, in his 'Für Darwin,' states that Metschnikoff has observed 'that *Nebalia*, during its embryonal life, passes through the Nauplius- and Zoëa-stages, which in the Decapoda occur

[1] For a very full account of *Nebalia* see the twelfth Annual Report of the United States Geological Survey, Part I. Geology, Palæontology, and Zoology, 8vo, 1883 (Washington), 'A Monograph of the Phyllopod Crustacea of North America, with remarks on the order *Phyllocarida*,' by A. S. Packard, jun., pp. 295–592, and plates i.–xxxix. See also the *American Naturalist* for October, November, and December, 1882, vol. xvi. pp. 785, 861, 945.

[2] Pedunculated eyes are also present in *Branchipus* and *Artemia*, so that the stalked eyes of *Nebalia* can scarcely be regarded as an essentially distinctive character.

partly (in *Penæus*) in the free state.' 'Therefore,' he adds, 'I regard *Nebalia* as a Phyllopodiform Decapod.'

In 1872 Claus gave an account, with excellent figures, of the external anatomy of *Nebalia Geoffroyi*, and in 1876 he described the internal anatomy.

In 1875 in the account of the Atlantic Crustacea of the 'Challenger' Expedition, Willemoes-Suhm placed the *Nebaliadæ* among the *Schizopoda*.

In 1879 Dr. A. S. Packard, jun., in the 'American Naturalist,' vol. xiii. p. 128, proposed that *Nebalia* and its fossil allies should be placed in a new order, which he proposed to name the PHYLLOCARIDA. Dr. Packard writes:—

'The *Nebaliadæ*, represented by the existing genus *Nebalia*, have generally been considered to form a family of Phyllopod Crustacea. Metschnikoff, who studied the embryology of *Nebalia*, considered it to be a "Phyllopodiform Decapod." Besides the resemblance to the Decapods, there is also a combination of Copepod and Phyllopod characteristics. The type is an instance of a generalised one, and is of high antiquity, having been ushered in during the earliest Silurian period, when there were (when we regard the relative size of most Crustacea, and especially of living *Nebaliæ*) gigantic forms. Such was *Dithyrocaris*, which must have been over a foot long, the carapace being seven inches long. The modern *Nebalia* is small, about half an inch in length, with the body compressed, the carapace bivalved as in *Limnadia*, one of the genuine Phyllopods. There is a large rostrum overhanging the head; stalked eyes; and, besides two pairs of antennæ and mouth-parts, eight pairs of leaf-like, short, respiratory feet, which are succeeded by swimming-feet. There is no metamorphosis, development being direct.

'Of the fossil forms, *Hymenocaris* was regarded by Salter as "the more generalised type." The genera *Peltocaris* and *Discinocaris* characterise the Lower-Silurian period, *Ceratiocaris* the Upper, *Dictyocaris* the Upper-Silurian and the lowest Devonian strata, *Dithyrocaris* and *Argas* the Carboniferous period. Our existing north-eastern species is *Nebalia bipes* (Fabricius), which occurs from Maine to Greenland.

'The Nebaliads were the forerunners of the DECAPODA, and form, we believe, the type of a distinct order of Crustacea, for which the name PHYLLOCARIDA is proposed.'

The order PHYLLOCARIDA has been thus defined:—

PHYLLOCARIDA, Packard (1879). Body long, with five cephalic, eight thoracic, and eight abdominal segments, with a thin or chitinous skin; generally covered with a bivalved shell having a movable rostrum. Eyes pedunculated and faceted. Upon the under side of the head are two pairs of antennæ; the mandibles and two pairs of maxillæ furnished with palpi. The body-segments are compressed, they support eight pairs of large Phyllopodiform thoracic feet. The abdomen composed of eight large segments,[1] provided with six pairs of simple swimming-feet fringed with setæ, of which the four anterior pairs are the largest, and the two posterior pairs are very small. The abdomen terminates in setaceous filaments, or in a telson divided into three or more parts. (Zittel, 'Handbuch der Paläontologie,' Munich, 1885.)

[1] The abdomen is nine-jointed, unless the last somite be considered as the telson (it is post-anal). It is a long and slender segment, and bears two very long narrow setigerous cercopods, closely resembling those of the Copepoda.

In 1880 Professor Claus, 'Lehrbuch der Zoologie,' writes, 'This remarkable form (*Nebalia*) was for a long time regarded as a Phyllopod, and in many of its characters it represents a connecting link between the PHYLLOPODA and the MALACOSTRACA. The structure and segmentation of the head and thorax resembles that of the Malacostraca, but the terminal region of the abdomen does not present the special form of a caudal plate or telson. In *Nebalia* we probably have to do with an offshoot of the Phyllopod-like ancestors of the MALACOSTRACA, which has persisted to the present time.' He adds, '*Nebalia* is best placed in a special group LEPTOSTRACA, between the ENTOMOSTRACA and MALACOSTRACA. The Palæozoic genera *Hymenocaris*, *Peltocaris*, &c. would have to be placed in such a group.'[1]

'It is,' writes Professor Claus, 'in the highest degree probable that all these' (Palæozoic PHYLLOCARIDA) 'are not true Phyllopods, but have belonged to a type of Crustacea, of which now there are no living representatives, but which, taking their origin from forms allied to the lower types of Entomostraca, have prepared the way for the Malacostracan type. Such a connecting link, which has served to the present day, we evidently find in the genus *Nebalia*.'[2]

In his 'Handbuch der Paläontologie,' Munich, 1885, Professor Dr. K. A. Zittel adopts Packard's order PHYLLOCARIDA, but places it under the MALACOSTRACA, and between the EDRIOPHTHALMIA and the MEROSTOMATA.

In his article on the Palæozoic allies of *Nebalia*, Dr. A. S. Packard, jun., thus sums up the PHYLLOCARIDA: 'From our total lack of any knowledge of the nature of the limbs of the fossil PHYLLOCARIDA, we have to be guided solely by analogy, often an uncertain and delusive guide. But in the absence of any evidence to the contrary, there is every reason to suppose that the appendages of the head, thorax, and abdomen were on the type of *Nebalia*, since there is such a close correspondence in the form of the carapace, rostrum, and abdomen. But whatever may be the differences between the fossil forms represented by *Ceratiocaris*, &c., they certainly seem to approach *Nebalia* much nearer than any other known type of Crustacea; they do not belong to the DECAPODA; they present a vague and general resemblance to the zoëa or larva of the Decapods, but no zoëa has a telson, though one is developed in a postzoëal stage; they do not belong to any other Malacostracous type, nor do they belong to any existing Entomostracous type, using those terms in the old sense. No naturalist or palæontologist has referred them with certainty to the Decapods or to any other Crustacean type than the Phyllopods. To this type (in the opinion of Metschnikoff and Claus, who have studied them most closely) they certainly do not belong, and thus reasoning by exclusion they either belong to the group of which *Nebalia* is a type, or they are members of a lost, extinct group. The natural conclusion, in the light of our present knowledge, is that they are members of the group represented by the existing *Nebalia*.' 'The differential characters separating them from the Decapods or any other Malacostracous type are—

1. The loosely-attached carapace, the two halves connected by an adductor muscle.

[1] Claus, translated by Sedgwick (Cambridge), p. 448 (footnote), 8vo, 1884. The *Leptostraca* (Claus) are thus defined: 'Crustacea with thin, folded carapaces, mostly bivalved, under which all the thoracic rings remain as free segments' (Zittel, 'Handb. Paläontol.' 1885, p. 655).

[2] Claus in Siebold and Kölliker's 'Zeitschrift,' xxii. 1872, p. 329.

2. The movable rostrum, loosely attached to the carapace.

3. The very long and large mandibular palpus; the long slender appendage of the first maxilla, and the very long bi-ramous maxillæ.

4. The absence of any maxillipeds.

5. The eight pairs of pseudo-phyllopod thoracic feet, not adapted for walking.

[To these we would add—5*a*. The "telson" long and slender, with two long narrow setigerous cercopods as in the Copepoda.]

6. The animal swimming on its back.

7. No zoëa-formed larva.

The characters which separate it from the Phyllopods are—

1. Carapace not hinged; a rostrum present.

2. Two pairs of well-developed long and large multiarticulate antennæ; the hinder pair, in the male, longer than the first pair.

3. The thorax and its appendages clearly differentiated from the abdomen.'[1]

Nebalia has been so long regarded as the surviving representative of those more ancient and gigantic forms of PHYLLOCARIDA, which existed in such numbers in the Cambrian and Silurian Seas, and became nearly extinct towards the close of the Carboniferous epoch, that any decision affecting its zoological position cannot be a matter of indifference to the palæontologist.

But after studying its larval development and adult structural modifications, we arrive at the fact that *Nebalia* is a more generalised type than is ordinarily to be found at the present day, 'combining Copepod, Phyllopod, and Decapod-like features, with other more fundamental characters of its own' (Packard), which preclude us from regarding it as a true Malacostracan, and, although ancestrally related to that order, it nevertheless does not attain, in our opinion, to the Malacostracan grade of development.[2] They should therefore be arranged in a distinct order (the PHYLLOCARIDA) between the ENTOMOSTRACA and the MALACOSTRACA, as suggested by Claus. But if it is undesirable to have such an outstanding group, then we contend that the balance turns in favour of retaining it in the former division, if not in the order PHYLLOPODA as heretofore.

Thus we conclude:—

1. Some of the supposed 'Phyllopod shields' from Budesheim and Bicken are probably *Aptychi* of *Goniatites*.

2. That for others of the Palæozoic Phyllopods, described in the Reports of 1883–84, this explanation is inadmissible.

3. That those which cannot be referred to *Aptychi* are still, in all probability, Phyllopods.

4. That the *Nebalia*-like forms, now placed in the order PHYLLOCARIDA, are *certainly not Decapods*. And even if they may not with propriety be retained any longer in the old order PHYLLOPODA (of which we are by no means sure), yet they may more correctly be placed beside

[1] *American Naturalist*, 1882, vol. xvi. p. 951; and *Monograph N. Amer. Phyllopods*, &c. 1883, pp. 447–8.

[2] Dr. Packard writes, 'There is little to indicate that the Schizopods (*Mysis*, &c.) have descended from a *Nebalia*-like form, but rather from some accelerated zoëa form; while the Phyllocarida *have had no Decapod-blood in them*, so to say, but have descended by a separate line from Copepod-like ancestors, and culminated, and even began to disappear, before any Malacostraca, at least in any numbers, appeared.' *American Naturalist*, 1882, vol. xvi. p. 873.

them in the Entomostraca than in the Malacostraca, seeing they have not actually attained to the grade of the latter, but only approached to its larval development; whilst to the former the adult *Nebalia* has many very strong points of affinity.

§ II. Ceratiocaridæ.—Dr. Packard's observations on the structure of the Phyllopods, and his studies of the comparative anatomy of living and fossil forms, supply the palæontologist with sound reasoning in referring the *Phyllocarida* to the Nebaliad type as a centre for a great group of obscure fossil forms, and as a starting-point for the Decapoda. We have referred to his views in some detail in the foregoing pages.

Order. Phyllocarida, Packard.

Genus Ceratiocaris, M'Coy.

The generic characters of *Ceratiocaris* have been described by M'Coy, Salter, H. Woodward, and Barrande in their several works and memoirs referred to in the sequel. James Hall, R. P. Whitfield, A. S. Packard, J. M. Clarke, Fr. Schmidt, C. E. Beecher, O. Novák, and others have added much information, general and special, on this and allied genera. The appended synonymy of the genus supplies full references to published notices on *Ceratiocaris* and some of its allies.

We offer the following diagnosis of *Ceratiocaris*. Carapace bivalved, probably with membranous attachment, no distinct hinge-joints being observable; valves subovate, semiovate, subquadrate, or trapezoidal; contracted in front with the end sharp or rounded above the median line of the valve; more or less truncate behind. Rostrum elliptical in shape, of a single lanceolate piece, chevron-marked. Antennæ (?) obscure. Teeth often apparent. Body many-jointed, with fourteen or more segments, of which 4–7 extend beyond the carapace, ornamented with delicate raised lines. Some or all of these segments bore small lamelliform branchial appendages.[1] Last segment, the longest, supporting three caudal spines, namely: (1), a strong tapering telson (style), thick at the top or proximal end, with its three-knobbed articulating surface (resembling that in the telson of *Limulus*), pointed at the other, and more or less spinose, as shown by the bases of little prickles; and (2), two shorter, simpler, lateral appendages (stylets). The surface of the valves has a lineate ornament, and the ventral margin has a thin raised rim.

Respecting the abdominal appendages which Mr. R. Etheridge, jun., described in Appendix III. of the 'Memoirs Geol. Survey Scotland: Explanation of Sheet 23,' 1873, p. 93, he there remarks:—' A further advance in the structure of this genus of Crustacea has been satisfactorily established from specimens obtained at Lesmahagow by the Collector of the Geological Survey, viz. the presence of respiratory locomotive appendages. On a slab of thin-bedded shale are exposed the abdominal segments, telson, and caudal appendages of a *Ceratiocaris*. From the ventral margin of the terminal segment, to which are attached the telson-spines (*Leptocheles*, M'Coy), proceeds a broad, paddle-shaped, membranous (?) expansion, presenting a strong marginal outline, with a transversely striated surface. This is followed by another similar appendage, proceeding in the same manner from the penultimate segment (somite). Along the dorsal margin there is seen what appears to be the

[1] See the 'Sixth Report on Fossil Crustacea,' *Brit. Assoc. Report* for 1872, p. 323.

remains of one of the corresponding "foot-gills," on the other side, bent back upon itself, and thus thrust out of place. The free ends of these foot-gills are attenuated to more or less rounded points. They do not show any evidence of having possessed a marginal fringe. The discovery of these branchial locomotive appendages tends to ally *Ceratiocaris* still further with the genus *Nebalia*. See "Geol. Mag." vol. ix. p. 564. *Loc.*: No. 292 (Linburn or Linn Burn, about two miles N. of Muirkirk, Lanarkshire). In thin-bedded shale (Upper Ludlow). Collected by A. Macconochie.' Mr. R. Etheridge, jun., again alludes to this interesting subject in the 'Annals and Mag. Nat. Hist.' ser. 4, vol. xiv. 1874, p. 9.

A. *British Species.*

1. CERATIOCARIS MURCHISONI (Agassiz), and its variety LEPTODACTYLUS (M'Coy).

Some imperfect caudal appendages or spines (telson or style, and lateral spines or stylets), from the Uppermost Ludlow strata, near Ludlow, were figured in Murchison's 'Silurian System,' in 1839, as fish-defences. These were recognised by Prof. F. M'Coy in 1853 as being very similar to some analogous fossils, referred by him at first (in 1849) to a slender-clawed kind of *Pterygotus* from the Lower Ludlow, at Leintwardine, near Ludlow, which he separated from that genus as *Leptocheles leptodactylus.* M'Coy suggested that Murchison's fossil should be known as *L. Murchisoni.*[1]

In each case we have only caudal spines to deal with; but M'Coy's specimens ('Brit. Pal. Foss.' pl. 1 E, figs. 7, 7*a*, 7*b*) are much more slender than Murchison's ('Sil. Syst.' pl. 4, figs. 10 and 64, and 'Siluria,' pl. 19, figs. 1, 2), and less strongly ribbed; and therein they seem at first sight to have specific differences.

Several good examples of more or less perfect sets of the three caudal spines corresponding in size, strength, and ribbing with Murchison's fossils have been met with. These show evidence of lines of prickles (by the presence of little pits, representing their bases, along one or more lines); and on close examination the engravings in the 'Sil. Syst.' and 'Siluria' (the specimens have been lost) show some slight indications of this spinose ornament. This is not visible, however, in M'Coy's figures or specimens (Cambridge Museum, *a*/923, *a*/924). Of these latter, more delicate, caudal appendages, very few other examples occur.

In the collocation of these caudal appendages with their respective *carapaces* we have some doubt and difficulty.

We have not found a carapace directly associated with any complete spines of either the *Murchisoni* or *leptodactylus* type except in the case of a very small specimen (M. P. G. x $\frac{1}{4}$), which appears to have the caudal appendages of *C. Murchisoni* and the carapace of Salter's '*leptodactylus.*' With regard to both, however, the late Mr. J. W. Salter satisfied himself that he knew their special carapaces, for he described them at p. 157 of the 'Ann. Mag. Nat. Hist.' for March 1860: where also he refers both species to the *Ceratiocaris* of M'Coy. Judging from his Latin diagnoses, he allocates to the former—'a cephalothorax (carapace) two inches long, oblong, convex, ornamented with interrupted, nearly-straight, wide-apart lines. The caudal appendages long, sub-cylindrical; the central spine

[1] Prof. M'Coy's observations are as follows:—'. . . As before mentioned, figs. 9, 10, and 11 [*Sil. Syst.* pl. 4; omit figs. 9 and 11], representing the so-called *Onchus Murchisoni*, Ag., are almost identical in form, size, sculpturing, and all other characters (as far as they are represented in these drawings), with the distinctly didactyle pincers which I have figured (*Brit. Pal. Foss.* pl. E, fig. 7) from Leintwardine, under the name *Lept. leptodactylus*. . . . If this approximation prove correct, the fossil should in future be called *Leptocheles Murchisoni* (Ag. sp.).'—*Q. J. G. S.* vol. ix. 1853, p. 13.

(telson) strong, bulbous at its base, and with a strong dorsal rib; the side spines long. All ribbed. The whole animal medium-sized. Specimens possessed by the geologists at Ludlow and by the Museum of Practical Geology.' The carapace described here does not agree with any that we can associate with the caudal spines intended. Nor do we find at Ludlow exactly the kind of carapace required.

To *C. leptodactylus* Mr. Salter apportioned—'a cephalothorax long, triangular, acute in front, broad and rounded behind. Free abdominal segments 7–8 in number, subquadrate, deeply impressed at the sides. Caudal appendages long, striate; the central spine (telson) scarcely thicker than the long lateral spines. Surface of the head (carapace) smooth, or marked with only very short sparse lines. Abdominal segments strongly striate. The whole animal elongate and more than a foot long.' One particular specimen in the Mus. Pract. Geol. is referred to by Mr. Salter at p. 158. We are at a loss here also in fitting the indicated (slender) appendages to the carapace described. We have examined this and other good specimens, labelled *C. leptodactylus* by Mr. Salter or at his direction, in which the *carapace* agrees with his description. One carapace is of large size, nearly perfect, about 125 mm. (5 inches) long, by 55 mm. at greatest height; M. P. G. x $\frac{1}{5}$, 'Catal. Cambr. Sil. Foss.' 1878, p. 142. A specimen nearly perfect, M. P. G. x $\frac{1}{7}$ ('Catal.' 1878, p. 142), 60 mm. long by 28 mm., gives no certain indication of the length of its telson and its two stylets, for they are crushed off short. The abdomen exposed is about 50 mm. In specimen D of the Ludlow Museum, which has the proximal portion only of the caudal spines preserved, and in specimen B, with the appendages also broken off short, the telson was ribbed and pitted (=prickly), thereby differing from the spines known as *C. leptodactylus* (M'Coy).

There is also a well-preserved *small* specimen (M. P. G. x $\frac{1}{9}$, 'Catal.' 1878, p. 142), with its carapace measuring only 25 mm. in length and 11 mm. in height, from the Lower Ludlow of Bow Bridge, Ludlow. This is labelled '*C. leptodactylus*,' and belongs to the same species as the foregoing. Its caudal appendages are perfect, with the telson (25 mm.) about one-third of the length of the whole animal; but they differ from M'Coy's *C. leptodactylus*, for they are not only ribbed or ridged, but the telson was prickly; the laterals were probably rather more than half its length. Specimen M. P. G. D $\frac{22}{13}$, however, from Dudley, is a thin spiniform fragment, faintly striated, like *C. leptodactylus*.

Altogether the telson (style) and stylets of these specimens have a very close resemblance to those known as *C. Murchisoni* (see above, p. 336). One example, from Dudley, described and figured as such by H. Woodward in the 'Geol. Mag.' vol. iii. p. 204, pl. x. fig. 8 (stylets and the upper moiety of the style, 90 mm., even more than 5 inches long when perfect), was doubtlessly proportionate to the large carapace, M. P. G. x $\frac{1}{5}$, above alluded to, as belonging to an animal more than 12 inches long; the carapace, exposed segments, and the telson being each a third of the whole length.

Other good specimens of these caudal appendages are :—

Ludlow Museum, C. Lower Ludlow; Leintwardine.[1] Lower portion of the style and stylets, 130 mm. ($5\frac{1}{8}$ inches).

[1] This is mounted with specimen D as one specimen; but the discrepancy between the two parts is readily seen. It is referred to in the Rev. J. D. La Touche's 'Geol. Shropshire,' &c. p. 77.

Owens College Museum. From near Ludlow. Style and stylets, not perfect, 105 mm.

M. P. G. $\frac{23}{36}$, 'Catal.' 1878, p. 118. Leintwardine. Style, 103 mm. This and a piece of a carapace associated are labelled '*C. tyrannus*, Salter.'

Mr. Morgan's collection: Cwm-y-sul, near Welshpool (Wenlock Shale). Fragment of style, with stylets, 95 mm.

Ludlow Museum, P. Lower Ludlow; Trippleton, near Leintwardine. Lower part of style and stylets, 80 mm.

Oxford Mus. B, telson about 105 mm. (more than 4 inches); also C and D. The head or proximal end of the telson is marked with longitudinal wrinkly lines. From near Ludlow.

Broken pieces:—

Murchison's, fig. 10, pl. 4, 'Sil. Syst.' (fig. 1, pl. 19, 'Siluria'), Upper Ludlow beds. One piece measures 92 mm., and more, if the piece lying at its end belonged to it.

Woodward's fig. 9 (M.P.G. $\frac{17}{15}$, 'Catal.' p. 84), Casterton, Low Fell, Kirkby-Lonsdale; Wenlock Shale. Fragments, 50 mm.

Cambridge Museum, *b*/7. Upper Ludlow beds; Benson Knot, Kendal. Fragment, 43 mm.

M. P. G. x $\frac{1}{29}$, 'Catal.' p. 142. Upper Ludlow; Benson Knot, Kendal. Fragments, 40 mm.

Cambridge Museum (Marr Coll.). Upper Coldwell beds = Wenlock; south of Coldwell quarry, Windermere. Part of style and ends of stylets, 40 mm.

Small fragments, smooth (? *Murchisoni*); straight and ribbed; curved and ribbed (? *Murchisoni*); M. P. G. x $\frac{1}{30}$, $\frac{1}{31}$, $\frac{1}{32}$; from the Downton Sandstone; Kington, Herefordshire.

Strongly ribbed and pitted (= spinose), British Museum; Bury Ditch, Salop; and Oxford Mus. D, Ludlow.

Both in M'Coy's *C. leptodactylus* and *C. Murchisoni* (the latter = Salter's *C. leptodactylus*, in part, and his *C. tyrannus* and *C. gigas*) the last abdominal segment is striated with straight, somewhat inosculating, raised lines; and the other segments, where preserved, are similarly marked. A somewhat crushed specimen from Danefield, Kington, Herefordshire (Lower Ludlow), M. P. G. x $\frac{1}{2}$ 'Catal.' p. 141, showing a terminal segment with similar nearly straight, but wriggly, inosculating, thin riblets, and ridged and fluted caudal appendages, as far as preserved, has been labelled '*C. gigas*' by Salter; but this may well belong to the series here placed as *C. Murchisoni*; *C leptodactylus* being restricted to M'Coy's specimens and figs. 7, 7*a*, 7*b*, and a few other slender and simply striate forms. The carapace belonging to these is not yet known. It is quite possible that these rare and thinner styles and stylets may have belonged to some variety of *C. Murchisoni*. In this case a separate specific name is not required for them, and they should be merged in *C. Murchisoni*, as arranged in H. Woodward's 'Catal. Brit. Foss. Crust.' 1877, p. 71.

There is little or no doubt that the figure given by Mr. Salter in the 'Catal. Cambr. Silur. Fossils,' 1873, pp. 16, 164, and 178, as illustrative of the genus, is *C. Murchisoni*, as here defined. The *eye-spot*, however, and the *hinge-'oints* are, in our opinion, superfluous and not substantiated.

1860. *Ceratiocaris leptodactylus* (M'Coy), Salter. 'Ann. Mag. N. H.' ser. 3, vol. v. p. 157.
1867. *Leptocheles* (*Ceratiocaris*) *leptodactylus* (M'Coy). Salter, in 'Siluria,' 4th ed. (including 'Sil. Syst.'), p. 237.
1867. *Ceratiocaris leptodactylus* (M'Coy). Salter, in 'Siluria,' 4th ed. (including 'Sil. Syst.'), p. 516.
1873. *Ceratiocaris leptodactylus*, Salter. 'Catal. Camb. Sil. Foss.' p. 164.

Taking Mr. Salter's description of the carapace of '*leptodactylus*' and the appendages of '*Murchisoni*' as really both belonging to the latter, and the more slender caudal spines (*leptodactylus* of M'Coy) as belonging to a variety of the latter, we have looked for the two-inch oblong carapace which Mr. Salter thought he had found for *Murchisoni* ('Ann. Mag. Nat. Hist.' *l.c.*), but we have not met with it at Ludlow, as led to expect by his remarks; nor is it in the Museum of Practical Geology, to which also he refers us. Indeed, we cannot help thinking that some confusion of the specimens is hereby indicated.

The carapace of *C. Murchisoni* (as defined by us) is pyriform, or acutely subovate, deep behind, narrow in front; gently convex on the back; outlined by a bold elliptical curve on the ventral margin, which rises up to form with the dorsal edge a sharp angle in front, above the

median line of the valve; but this and other features were varied by age and sex, and have been modified by pressure in the different specimens. The antero-ventral margin is sometimes indrawn, making the point in front more acute. The hinder margin is truncate with an elegant ogee curve, full below, and ending above in the postero-dorsal angle, often but not always sharply defined. In some cases the ventral margin is much deeper than in others. Some fragments of carapaces from Leintwardine (Ludl. Mus. O., and M. P. G. $\frac{23}{36}$) are ornamented with longitudinal lines or striæ of varying strength.

Seven abdominal segments are usually exposed.

Good specimens of *C. Murchisoni* (Agass.):—

M. P. G. x $\frac{1}{5}$.—Carapace, 125 × 55 mm., with acute prow. Smooth, longitudinal linear ornament. Long form of carapace. Leintwardine.

M. P. G. x $\frac{1}{7}$.—Carapace, 60 × 28 mm. Smooth and glazy.
Seven segments, about 50 mm. (the last one about 20 mm.) Telson crushed. Long form of carapace. Leintwardine.

Ludl. Mus. D.—Carapace, 50 × 30 mm. Smooth.
Seven segments, 55 mm. (the last one 20 mm.) Some with straight striæ.
Telson imperfect. Short form of carapace. Leintwardine?

Ludl. Mus. B.—Carapace, about 50 × 30 mm. Short form of carapace.
Exposed segments (crushed up), 50 mm. With straight, wriggly striæ.
Telson broken. Leintwardine.

M. P. G. x $\frac{1}{6}$.—Carapace, 40 × 20 mm., with acute prow. Smooth and glazy; rough at the place of the teeth.
Five? segments, about 30 mm. Long form of carapace. Leintwardine.

M. P. G. x $\frac{1}{9}$.—Carapace, 25 × 11 mm. Small, smooth, sharp in front, marked by teeth inside.
Seven? segments, 28 mm. (the last one 14 mm.) Linear ornament.
Telson, 25 mm. Ridged and pitted (spines). (Stylets about 12 mm. Ridged.) Long form of carapace. The whole animal $3\frac{1}{8}$ inches in length. Bow Bridge, near Ludlow.

Ludl. Mus. A.—Carapace, 24 × 13 mm. Small, smooth, subovate, sharp in front.
Seven segments, 30 mm. (the last one 12 mm.) Longitudinally striate.
Telson imperfect (12 mm. preserved). Medium form of carapace. Leintwardine?

Oxford Mus. J, K, and Q.—Small individuals in the Grindrod Coll. from the Lower Ludlow, with features corresponding with those of *C. Murchisoni*.
K is a carapace especially agreeing in form, though measuring only 15 × 6 mm. J is still smaller; it is much crushed, and about 8 × 4 mm., with an abdomen of 6 segments, probably imperfect, 9 mm. In Q the carapace (18 × 10 mm.) has been misshaped by pressure; the abdomen was about 7 mm.; and the little telson was strongly ridged, and at least 10 mm. long.

Addendum.

1853. *Dithyrocaris Murchisoni* (Agass.), Geinitz. 'Verstein. Grauwackenformation in Sachsen,' u.s.w. Heft ii. p. 24, pl. 19, fig. 13.

1866. *Ceratiocaris Murchisoni*, Jones. 'Ann. Mag. Nat. Hist.' ser. 3, vol. xviii. p. 40.

This is the distal end of a tapering, costulate telson (or stylet ?), and is quite comparable with *C. Murchisoni* (Agassiz), as indicated by Dr. H. B. Geinitz. It was obtained from the Silurian Grauwacké beds of the Gunzenberg, between Möschwitz and Pöhl, near Plauen, together with Graptolites, Orthoceras, and Pterinea.

2. Ceratiocaris Ludensis, H. Woodward.

1871. *Ceratiocaris Ludensis*, H. Woodward. 'Geol. Mag.' vol. viii. p. 104, pl. 3, fig. 3.
1884. *Ceratiocaris Ludensis*, Jones and Woodward. 'Geol. Mag.' dec. 3, vol. i. p. 396.

This large and indeed gigantic *Ceratiocaris*, represented by seven abdominal segments, with the caudal appendages of telson and two stylets, in the Ludlow Museum, has been described in the 'Geol. Mag.' for March 1871, and illustrated with a reduced figure. The carapace is there estimated as having probably been eight inches in length. The segments giving eight inches, and the telson being about nine inches in length, the animal would be more than two feet in total length. As pointed out in the paper referred to, the telson is certainly the longest known. Thus we find the relative proportions to be for *C. Ludensis*, H.W., 144; *C. Murchisoni* (Agass.) 128 (as defined above); *C. Deweii* (J. Hall), 100; *C. Bohemica*, Barr. (Brit. Mus.), 84; *C. stygia*, Salter, 32; *C. Nœtlingi*, F. Schmidt, 26; *C. papilio*, Salter, 16.

The segments are ornamented along the back with imbricated or lattice-like raised angular lines, which pass downwards on the sides into oblique and then curved wrinkly lines, and these on some of the segments form an irregular reticulation at the anterior margin. The ultimate segment is striated longitudinally with interrupted and inosculating lines. The spines are stout, tapering slowly, slightly curved inwards (downwards), delicately ribbed, and bear close-set marks of the bases of small spines between or on some of the ridges.

This fine specimen is imbedded in the greenish-grey, sandy, laminated mudstone of the Lower-Ludlow series, at Church Hill, Leintwardine, near Ludlow, with Graptolites. It was found by the late Mr. H. Pardoe, and is preserved in the Ludlow Museum.

3. Ceratiocaris papilio. Salter.

1859. *Ceratiocaris*, Salter. In Murchison's 'Siluria,' 2nd (3rd) edit. p. 262, woodcut fig. 1, p. 538.
1860. *Ceratiocaris papilio*, Salter. 'Ann. Mag. Nat. Hist.' ser. 3, vol. v. p. 154, woodcut fig. 1, and p. 155.
1865. *Ceratiocaris papilio*, Salter and H. Woodward. 'Catal. and Chart Foss. Crust.' p. 17 (not fig. 5).
1865. *Ceratiocaris papilio*, H. Woodward. 'Geol. Mag.' vol. ii. p. 403, pl. 11, figs. 1 and 2.
1867. *Ceratiocaris papilio*, Salter. In 'Siluria,' 3rd (4th) edit. p. 236, woodcut fig. 1 (not fig. 2), and p. 516.
1873. *Ceratiocaris papilio*, Salter. 'Catal. Camb. Sil. Foss.' p. 178.
1873. " " R. Etheridge, jun. 'Mem. Geol. Surv. Scotl. Expl. Map 23,' pp. 55, 56.
1876. *Ceratiocaris papilio*, Armstrong and others. 'Catal. W.-Scot. Fossils,' p. 24.
1877. " " H. Woodward. 'Catal. Brit. Foss. Crust.' p. 71.
1878. " " Huxley and Etheridge. 'Catal. Camb. Sil. Foss.' p. 142.

Of the two species, so abundant in the Upper-Ludlow Shales of the Logan Water, near Lesmahago, in Lanarkshire, and described (unfortunately without good figures) by J. W. Salter in the 'Ann. and Mag. Nat. Hist.' for March 1860, we have examined many good specimens. As mentioned by Salter, one (*C. papilio*) has the carapace more oblong than the other (*C. stygia*), which is deepened by a greater or less angularity on its ventral margin. In the woodcut diagrams at p. 154 of his

memoir, fig. 1 is the oblong form, and figs. 2 and 3 have the deep ventral angle (*C. stygia*), and yet they are all there termed *C. papilio*, evidently from oversight. In the Lesmahago district multitudes of the two species seem to have been imbedded in the black mud (now shales); and frequent references to these interesting deposits are made in 'Siluria,' 'Memoirs of the Geological Survey of Scotland' (especially 'Explanation of Map 23,' p. 49, &c.), in other works on Scottish Geology, in geological manuals &c., and in Dr. J. R. S. Hunter's papers in the 'Trans. Geol. Soc. Glasgow,' vol. vii. pp. 56, 272, &c.

Carapace sub-oblong; straight on the back, gently curved below; like the prow of a boat in front, and truncate with an ogee curve behind. The anterior extremity is rather sharp and is rarely preserved; it slopes with a gentle curve downwards and backwards from the antero-dorsal angle to the ventral margin. The latter is somewhat convex in outline, with its greatest fulness near the middle and rather forward, but varying with every specimen, all being more or less squeezed out of their true shape. The front moiety usually keeps its shape more truly than the posterior region, of which sometimes the dorsal angle (as in Brit. Mus. '41896,' '41897'), and sometimes the boldly-curved ventral portion (as in Brit. Mus. '41894,' '58669'; Cambridge Mus. *b*/135; and M. P. G. x $\frac{1}{15}$) becomes the more prominent. The surface of the valves is delicately striate, with longitudinal lines, curving parallel with the ventral margin, and coarser below than near the back. In some specimens the lines are seen to converge at, or rather, as it were, to start from, the postero-dorsal angles. The body-segments are obliquely striated. The telson (style), relatively stout, and very little longer than the laterals or stylets, was faintly ridged and perhaps prickly or spinose. The whole adult animal was probably from four to six inches long.

Having seen but few specimens in which the caudal appendages are well preserved in their place (as in Brit. Mus. '41894') we get only few good measurements.

Mr. Salter says that only three or four of the abdominal segments were free (external to the carapace), but probably there were even five; for in one specimen (Brit. Mus. '58669') five segments of large size, now loose and reversed, were probably exposed beyond the carapace; and in another (Brit. Mus. '41895') four, with an imperfect fifth, have been shifted out of place. The segments, excepting the last one, appear in their compressed condition to be half as long as high, and the last one as long as three of the others.

In Brit. Mus. '41894,' the carapace is 60 mm. long by 30 mm. deep (or high), and probably once rather deeper, having suffered from pressure. The penultimate segment is 10 mm. long, and if there were four of that length (40 mm.), with the ultimate segment, the body-rings would be nearly 80 mm. The telson was 25 mm. (stylets 18 mm.) Thus, altogether, the animal was about 152 mm., or 6 inches, in length.

Brit. Mus. '58669' has a longer (narrowed) carapace, five body-rings, and a broken telson; altogether, $6\frac{1}{4}$ inches long.

In another, but smaller, individual (Brit. Mus. '41895') the carapace, 40×20 ? mm.; segments, 40 mm., but shortened; and style, about 20 mm, (stylets, 15 mm. each), make about 100 mm., or four inches, of total length.

In ten good specimens from Lesmahago we have seen two of carapace only; and in all the others the body-portion is shifted, and in six of them

it is quite reversed—that is, lying at the anterior instead of the posterior end, as described by Mr. Salter ('Siluria,' 1867, p. 236, &c.).

The specimen Cambridge Mus. *b*/135 has the rostrum lying at an angle across the anterior extremity.

Of *C. papilio*, good specimens from Lesmahago:—

Cambridge Mus., *b*/135. M. P. G. x $\frac{1}{15}$, x $\frac{1}{22}$.

Brit. Mus. 41894, 41895, 41896, 41897, 45161, 47989, 58669.

We have seen also some fossil carapaces from Benson Knot, Kendal (Upper Ludlow) which agree perfectly in form and proportions with *C. papilio* from Lesmahago, also in ornament, except that the postero-dorsal convergence of the striæ is not present. These are Brit. Mus. some of those marked '44342'; M. P. G. x $\frac{1}{4}$ ('Catal.' 1878, p. 141); and Cambridge Mus. *b*/35. They range from 65 mm. long and 32 mm. high to 75 × 40 mm. Also a large imperfect specimen and some fragments in brown shale from Linburn, near Muirkirk (Brit. Mus., all marked '58878'). The specimen *b*/35 is included in *C. inornata*, M'Coy, by Mr. Salter, 'Catal. C. S. Foss.' 1873, p. 177.

Moreover, the specimen N in the Ludlow Museum has the proportions and appearance of *C. papilio*, as far as it is preserved (wanting the antero-dorsal angle), from Church Hill, Leintwardine.[1]

4. Ceratiocaris stygia, Salter.

1859. *Ceratiocaris*, Salter. In Murchison's 'Siluria,' 2nd (3rd) ed. p. 262, woodcut fig. 2.
1860. *Ceratiocaris stygius*, Salter. 'Ann. Mag. Nat. Hist.' ser. 3, vol. v. p. 154, woodcut figs. 2, 3 (fig. 1 is *C. papilio*).
1865. *Ceratiocaris papilio*, Salter and Woodward. 'Cat. and Chart Foss. Crust.' p. 17, fig. 5.
1867. *Ceratiocaris stygius*, Salter. In 'Siluria,' 3rd (4th) ed. p. 236, woodcut fig. 2, and p. 517.
1873. *Ceratiocaris stygius*, Salter. 'Cat. Camb. Sil. Foss.' p. 178.
1873. " " R. Etheridge, jun. 'Mem. Geol. Surv. Scotl. Expl. Map 23,' pp. 55, 56.
1876. *Ceratiocaris papilio*, F. Rœm. 'Leth. geogn.' Th. i. 'Leth. pal.' pl. 19, fig. 4.
1876. " *stygius*, Armstrong and others. 'Cat. W.-Scot. Fossils,' p. 24.
1877. " " H. Woodward. 'Catal. Brit. Foss. Crust.' p. 73.
1878. " " Huxley and Etheridge. 'Cat. Camb. Sil. Fossils,' p. 142.

Carapace-valves trapezoidal; back straight, but curving down for a short distance to the mucronate dorsal angle of the anterior edge, which then slopes, with a slight convexity and at a sharp angle, downwards and backwards, to about the middle of the ventral margin, where the valve is deepest (highest); the other half of the ventral edge rises slowly with a straight or nearly straight oblique edge to the blunt postero-ventral corner, whence the truncate hind margin rises, with a gentle concave curve, to the sharp postero-dorsal angle. When the valves are spread open a triangular space is left between the antero-dorsal angles. This condition and the shape are well shown in the specimen M. P. G. x $\frac{1}{13}$. The outline is often modified by pressure in

[1] The very rich localities for these Silurian Phyllopods in the neighbourhood of Ludlow are enumerated and described in the Rev. J. D. La Touche's 'Handbook of the Geology of Shropshire, 1884,' pp. 26, 27, especially Ludford Lane, Bow Bridge, Leintwardine, Church Hill, and Trippleton Farm. See also the Rev. W. S. Symonds' 'Record of the Rocks,' 1872, p. 194, &c. for notices of Ludlow and its environs from a geologist's point of view.

other positions; but not to quite so great an extent, as the shape of *C. papilio* is altered by squeeze in some instances. The valves are delicately striate, with longitudinal lines curving parallel with the ventral edge, and crowded at the postero-dorsal angles. The body-segments, of which probably five were outside the carapace (though often the segments seem to have been pushed back within the carapace after death), are marked with delicate, raised, oblique, wrinkly lines on the sides, and ornamented on the back with an imbrication of angular lines, which pass down into the lateral oblique wrinkles, M. P. G. x $\frac{1}{19}$ and $\frac{1}{20}$. These joints are sometimes more than twice as high as long. The last one is as long as three of the others. The telson is apparently in some cases about half as long again as the stylets (as 50 is to 30); and some specimens show traces of thin costulæ, and perhaps of prickles. The whole adult animals were from 4 to 8 inches long.

Specimen M. P. G. x $\frac{1}{20}$ has the rostrum and teeth squeezed out loose near the front end. A large individual, Cambridge Mus. *b*/65, measures—

Carapace		83 × 55 mm.
Four segments	40	65 mm.
Last segment	25	
Telson		50 ,,
		198 mm., or nearly 8 inches.

A small specimen, M. P. G. x $\frac{1}{13}$, measures—

Carapace		40 × 26 mm.
Four segments	20	30 mm ?
Last segment	10 ?	
Telson		30 ,,
About		100 mm., or nearly 4 inches.

C. stygia was rather larger than *C. papilio*; its telson was larger; the carapace is markedly distinct by its trapezoidal outline, deep ventral region, and mucronate antero-dorsal angle, which was not nearly so often lost in fossilisation as the front angle of *C. papilio*. In its rostrum, teeth, superficial ornament of carapace and of body-rings, it seems to have closely resembled *C. papilio*. In ten good specimens from Lesmahago, two are simple carapaces; three have body-segments in places, and five have them shifted or reversed. In this respect *C. stygia* seems to have been rather less liable to the dissolution of the membranous attachments of the body than its associate *C. papilio*.

A postero-dorsal fragment in Cambridge Museum (Marr Coll.), from the Denbighshire series (Wenlock), at Dinasbran, Llangollen, showing fine striæ above, and coarse striæ below, and the usual convergence of striæ, belongs probably to *C. stygia*.

An anterior moiety of a valve from near Ludlow is in the Grindrod Coll., Oxford Mus. G.

Good specimens of *C. stygia* from Lesmahago are Cambridge Mus. *b*/136, *b*/65 (the last is referred to as *C. papilio*, evidently by mistake, in 'Cat. C. Sil. Foss.' p. 178); M. P. G. x $\frac{1}{13}$ and $\frac{1}{14}$, x $\frac{1}{16}$, x $\frac{1}{19}$, x $\frac{1}{20}$, x $\frac{1}{21}$; and B. M. 41898, 45154, 45155, 45156.

In the 'Mem. Geol. Surv. Scotl. Expl. Map 23,' 1873, at p. 49, Mr. R. Etheridge, jun., enumerates the places near Lesmahago and Muirkirk, in Lanarkshire, where *Ceratiocarides* have been found by the Surveyors, namely—

Ceratiocaris papilio, Salter, at Dunside (Logan Water), Eaglinside Burn, Logan Water (2 m. S. of Lesmahago), and Linburn.
Ceratiocaris stygia, Salter, at Kip Burn (Logan Water), Eaglinside Burn, and Linburn.
Ceratiocaris, caudal appendages, at Long Burn (Logan Water), Dunside (Logan Water), Logan Water (6 m. S.W. of Lesmahago), Lann Burn, and Douglas Water.

Abdominal segments and appendages probably belonging to *C. stygia* are:—

Oxford Museum, E, seven segments and two spines, imperfect. The former ornamented with angles and oblique lines, the latter with a longitudinal lineation. Leintwardine.

B. M. '58878,' Linburn, Muirkirk. A telson, not quite perfect at base, 35 mm. long, associated with some obliquely-striate segments.

B. M. '41899,' Lesmahago. Four segments, 27 mm., and M. P. G. x $\frac{1}{25}c$, four segments, 30 mm., and in each case two short ensiform stylets attached (style wanting).

B. M. '41900' and '41901,' Lesmahago. Three abdominal segments, obliquely striate, and an ultimate segment with both oblique and straight striæ, probably due to two layers of the test. Telson, 30 mm. long; and two ensiform stylets, each about 13 mm. long.

M. P. G. x $\frac{1}{25}a$, $\frac{1}{25}b$, $\frac{1}{25}d$, Logan Water, Lesmahago. Segments with oblique striæ (one ultimate segment has straight striæ), not well preserved. Probably *C. stygia*, as named in the 'Catal.' 1878, p. 142.

One of the specimens in the Brit. Mus. marked '59648,' from Lesmahago, is a small acute-ovate carapace (25 × 15 mm.), to which is attached a complete, but somewhat crushed body of 13–14 segments, 6–7 (15 mm.) of which are external, and have appended two caudal spines, of which the strongest may be the telson (12 mm. long), and the other, nearly as long, one of the stylets.

At first sight this looks like the small *C. Murchisoni*, Ludl. Mus. A., but it differs considerably in details. If it be not a distinct species, it may be the young of *C. stygia*.

On another of the specimens, B.M. '59648,' from Lesmahago, are three loose small *bodies*, without carapaces. The largest has 13 or 14 segments, 45 mm., some of which are obliquely striate. Five measure 25 mm., and the last one 10 mm., equal to three of the others. The telson is 20 mm. long. Another such specimen, smaller and narrower, 35 mm. long, has 14 (?) segments; the last one 7 mm. long; appendages imperfect.

These may be the loosened and shifted abdomens of young individuals of *C. stygia* or *C. papilio*, both common at Lesmahago. They cannot be mistaken for the Carboniferous *Acanthocaris*, Peach, or the Devonian *Campecaris*, Page.

5. Ceratiocaris inornata, M'Coy.

1851. *Ceratiocaris inornatus* (Salter MS.), M'Coy. 'Brit. Pal. Foss.' p. 137, pl. 1 E., fig. 4.
1854. „ „ Morris. 'Catal. Brit. Foss.' 2nd edit. p. 102.
1859. „ „ Salter. In 'Siluria,' 2nd (3rd) edit. p. 532.
1860. „ „ „ 'Ann. Mag. Nat. Hist.' ser. 3, vol. v. p. 156.
1867. „ „ „ In 'Siluria,' 3rd (4th) edit. p. 516.
1873. „ „ „ 'Catal. Camb. Sil. Foss.' pp. 177, 178.
1877. „ „ H. Woodward. 'Catal. Brit. Foss. Crust.' p. 71.

This is the third of M'Coy's original species. The specimen in the

Cambridge Museum has its carapace ovate-oblong or somewhat boat-shaped in outline, 50 mm. (2 inches) long, height 18 mm.; moderately convex; straight or very slightly arched above and more strongly arched below (both edges are partly imbedded in the matrix of the original specimen, *b*/5, M'Coy's fig. 4). The anterior end (damaged) was neatly rounded, sloping up gracefully from below. The posterior is obliquely truncate from above downwards and outwards, with the postero-dorsal angle distinct, and the postero-ventral angle prominent and blunt. There is no eye-spot. Traces of longitudinal striæ are visible on the impressions of the valves in the grey, micaceous, Upper-Ludlow sandstone, from Benson Knot, near Kendal, Westmoreland; two specimens (one of them good) are in the British Museum, No. '44342,' from the same locality.

The foregoing description does not quite tally with the account of the species in the 'Brit. Pal. Foss.' p. 137, nor with that in the 'Ann. Mag. N. H.' *l. c.*, but is based on the original specimen and not on the *restored* figure in the 'Brit. Pal. Foss.' The figure annexed by Mr. Salter to his note on *C. inornata* in the 'Catal. Camb. Sil. Foss.' 1873, p. 178, is used also in connection with two other species at p. 16 and p. 164. In the latter case it is probably intended for '*C. leptodactylus*,' which we recognise as *C. Murchisoni*.

C. inornata approaches *C. papilio* in form in some cases, but we think that they are quite distinct species. There are some small carapaces, one from Lesmahago, B. M. '59648,' very near to *C. papilio* in form, and measuring 34 × 13 mm., and one from Benson Knot, B. M. '44342,' measuring 35 × 14 mm. These proportions are different from those of *C. papilio*. These two are rather smaller than M'Coy's original *C. inornata* (about 50 × 20 mm.), but have the same proportions, the normal height being $2\frac{1}{2}$ of the length; whilst *C. papilio* is larger and has less height in proportion, the length being only twice the height, or even less.

6. Ceratiocaris Oretonensis, H. Woodward.

1871. *Ceratiocaris Oretonensis*, H. Woodward. 'Geol. Mag.' vol. viii. p. 105, pl. 3, fig. 1.
1878. *Ceratiocaris Oretonensis*, H. Woodward. 'Cat. Brit. Foss. Crust.' p. 71.

This Carboniferous species, described in the 'Geol. Mag.' for March 1871, approaches closely to some of the forms of *Ceratiocaris* found in the Upper Silurian of Benson Knot—namely, *C. inornata*, M'Coy. The carapace (50 × 22 mm.) is larger, however, without attaining the size and proportions of *C. papilio*, which is also found there, and is not without an apparent relationship to the former, as noticed above. In again examining the specimens, we find that the anterior end is not so much rounded as in fig. 1, but is slightly and obliquely truncate; and the antero-ventral margin is more sloping and less convex; thus the greatest depth of the carapace is in the hinder half. Four specimens from the Yellow Carboniferous Limestone of Oreton and Farlow, Worcestershire, not well preserved. The indistinct, 'eye-spot,' mentioned at p. 105, is very problematical, and may have been caused by pressure on some internal organ (teeth?).

7. Ceratiocaris truncata, H. Woodward.

1871. *Ceratiocaris truncatus*, H. Woodward. 'Geol. Mag.' vol. viii. p. 106, pl. 3, fig. 2.
1878. *Ceratiocaris truncatus*, H. Woodward. 'Cat. Brit. Foss. Crust.' p. 72.

The smaller species occurring with the last (*C. Oretonensis*) was described and figured with it in 1871. The carapace (35 × 15 mm.) is well figured, except that (as the author remarks, p. 106) the slightly concave truncation of the hinder end is not well rendered by the artist. Its smaller size, sharp antero-dorsal angle, and nearly even ventral curve, distinguish it from its associates, but scarcely separate it, as far as outline is concerned, from some specimens of *C. inornata* at Benson Knot.

8. Ceratiocaris solenoides, M'Coy.

1849. *Ceratiocaris solenoides,* M'Coy. 'Ann. Mag. N. H.' ser. 2, vol. iv. p. 413, with woodcut.
1851. *Ceratiocaris solenoides,* M'Coy. 'Brit. Palæoz. Foss.' fasc. i. p. 138, pl. 1 E, figs. 5, 5*a*.
1854. *Ceratiocaris solenoides,* Morris. 'Catal. Brit. Foss.' 2nd ed. p. 173.
1860. *Cultellus? (Ceratiosolen?) rectus,* Salter. 'Ann. Mag. N. H.' ser. 3, vol. v. p. 160.
1873. *Ceratiocaris solenoides,* Salter. 'Cat. Camb. Sil. Foss.' p. 178.
1877. „ „ H. Woodward. 'Catal. Brit. Foss. Crust.' p. 71.

Prof. M'Coy founded the genus on this species and *C. elliptica* in 1849.

The original specimens in the Cambridge Mus. (*b*/40, *b*/41) are not exactly drawn in M'Coy's figs. 5 and 5*a*. The carapace is elongate, subcylindrical, slightly convex on the sides, with an even elliptical anterior curve, and an oblique truncation posteriorly. There are faint traces of longitudinal striæ on the hollow impressions of the valves in the matrix, and there is a slight trace of the ventral rim. The large one is 43 mm. long (fig. 5); the smaller specimen, fig. 5*a*, 27 mm., is apparently broken behind, but does not show the double valve there as given in the figure; we cannot distinguish any 'nuchal furrow,' nor is there any 'eye-spot': a mark consisting of two minute adventitious pits in the anterior third of one of the specimens, and a little hole in another, have been mistaken for it. Mr. Salter thought these little fossils were Molluscan;[1] but they certainly may well claim to be Phyllopods. There are other specimens in the Cambridge Mus.; also two small individuals, one 19 mm. and the other only 10 mm. (marked *f*/142) in length. In the Brit. Mus. there are four, rather large, but not well preserved specimens ('44342'). All the above come from the Upper-Ludlow grey micaceous sandstone of Benson Knot, near Kendal, Westmoreland.

9. Ceratiocaris gobiiformis, *sp. nov.*

A form closely approaching *C. solenoides* in shape, but smaller, more acute in front, usually more vertically truncate behind, and much more convex on the ventral border, accompanies *C. solenoides* in the Upper-Ludlow sandstone of Benson Knot. One of the specimens marked *b*/8, Cambridge Mus. is 27 mm. long by 9 mm. high; one in the Brit. Mus., No. '44342,' is 30 by 10 mm.; M. P. G. x $\frac{1}{18}$ ('Catal.' 1878, p. 142) is 31 by 11 mm. The valves seem to have been smooth. They distantly resemble in outline a deep-bodied, blunt-headed little fish, without its tail. It is possible that this may be a varietal or sexual form of *C. solenoides*, but it seems to be sufficiently well separated from its ally to require a distinctive name, so we will refer to it as *C. gobiiformis* in our list.

[1] See 'Ann. Mag. Nat. Hist.' *l. c.* p. 159, *note*; and Sedgwick's 'Lists of Kendal Fossils,' 'Wordsworth's Letters on the Lakes,' 1843–46, Appendix.

10. Ceratiocaris Salteriana, *sp. nov.*

Six specimens in different states of preservation, from the Lower-Ludlow strata, indicate the existence of a distinct species of *Ceratiocaris*, having a nearly oblong carapace, ornamented with delicate but strong horizontal parallel lines, rather wide apart.

Specimen Ludlow Mus. K., from Trippleton, near Leintwardine, has a carapace (23×12 mm.), five (?) abdominal segments (10 mm.), and appendages, of which the style (pitted with bases of little spines) is imperfect, but a stylet measures 5 mm.

Another carapace M. P. G. $\frac{22}{14a}$, from Bow Bridge, Ludlow, well preserved, is 30×15 mm., straight on the back, rounded at the ends, the front being highest, and the greatest depth of the carapace being at the anterior third of the ventral margin. A hinder moiety of another carapace accompanies the last mentioned.

In the Cambridge Univ. Mus. *a*/694 is a similar carapace nearly as well preserved (30×14 mm.). The ventral margin has a distinct raised rim. The striæ and interspaces differ in tint of colour on the cast. Some internal organs (teeth?) have caused a little break or hole, and a derangement of the striæ in the antero-dorsal region. This specimen is from the Lower-Ludlow Shale at Dudley.

Two specimens, also from the Lower Ludlow series, L and M in the Oxford Museum (Grindrod Coll.), evidently belong to this species, though they are far from being perfect in some details.

We wish to associate this rare but distinct species of *Ceratiocaris* with the name of our deceased friend Mr. J. W. Salter, who worked so long and so well on these and allied *Phyllopoda*.

11. Ceratiocaris cassia, Salter.

1860. *Ceratiocaris cassia*, Salter. 'A. M. N. H.' ser. 3, vol. v. p. 159.
1867. " " " In 'Siluria,' 3rd (4th) edit. p. 516.
1877. " " H. Woodward. 'Cat. Brit. Foss. Cr.' p. 70.
1878. " " Huxley and Etheridge. 'Cat. C. S. Foss. M. P. G.' p. 141.

The best preserved carapace-valve (22×11 mm.) we have seen is Brit. Mus. '44342,' from the Upper Ludlow of Benson Knot; Brit. Mus. '38400,' from the Lower Ludlow of Leintwardine is also good, but is crumpled so as to have its outline modified. Originally nearly oblong, slightly arched above and below, truncate with hollow curve behind, pointed and mucronate at the upper third in front. Ludlow Mus. E. and F. and M. P. G. x $\frac{1}{1}$ ('Catal. C. S. Foss.' 1878, p. 141), seen by Mr. Salter, are not quite perfect. They are from a roadside quarry S.E. of Trippleton Farm, near Leintwardine. Ludlow Mus. F. and Brit. Mus. '39400' retain traces of the abdomen: in the latter, 15 mm. long, without appendages; in the former much less is seen, and a short telson (about 5 mm.). The carapace is horizontally striate, and the telson is minutely pitted as if it had been spinose. The ventral margin had a delicate raised rim.

Ludlow Mus. H., also from Trippleton, is a very small oval relic of a valve (13×7 mm.) possibly of *C. cassia*, and a loose abdomen of 5–6 segments (16 mm.), with a neat little set of appendages, style, 6 mm., and two stylets, each 3 mm.

Ludlow Mus. G. may be a modified carapace of *C. cassia*: no locality is recorded for it.

12. Ceratiocaris, *sp. nov.* ?

Mus. Pract. Geol. x $\frac{1}{26}$ ('Catal. C. S. Foss.' 1878, p. 142), labelled '*C. vesica*,' is a small specimen, having its carapace and abdomen preserved in place. From the Lower Ludlow of Leintwardine. It differs very much from *Physocaris vesica*, although nearly of the same size. The carapace is subtriangular, 25 mm. long and 15 mm. deep at the middle of the ventral margin. The back is straight, but curved down at both ends to meet the steep upward slopes of the lower margin. The abdomen (15 mm.) comes out, as usual, from the upper part of the hinder region. It shows obscurely four segments (the ultimate one about 6 mm.), mostly striated obliquely. The appendages have been broken off short. The carapace is somewhat crumpled, and is roughened anteriorly, probably by the presence of internal organs (such as teeth, &c.).

It is possible that this may be a very young individual of *C. stygia*, to which it somewhat approximates by its subtriangular carapace, and its obliquely-striate segments. Otherwise it must be a distinct species.

Specimen Lud. Mus. J. (from Trippleton, near Leintwardine) has a smaller but nearly similar carapace (22 × 12 mm.); nearly straight on the back, deeply curved below, and with almost equal dorsal angles in front and behind, but sharp instead of being blunt.

13. Ceratiocaris robusta, Salter.

1851. *Pterygotus leptodactylus*, M'Coy (in part). 'Brit. Palæoz. Foss.' fasc. i. p. 175, pl. 1 E, figs. 7*c*, 7*d*.
1860. *Ceratiocaris robustus*, Salter. 'Ann. Mag. N. H.' ser. 3, vol. v. p. 158.
1867. „ „ „ In 'Siluria,' 3rd (4th) edit. p. 516.
1873. „ „ „ 'Cat. Camb. Sil. Foss.' p. 164.
1877. „ „ H. Woodward. 'Cat. Brit. Foss. Crust.' p. 71.
1878. „ „ Huxley and Etheridge. 'Cat. Camb. Sil. Foss. M. P. G.' p. 142.

This species was founded on the caudal appendages of a species the carapace of which has not yet been collated. The original specimens figured by M'Coy and referred by Salter to a new species are in the Cambridge University Museum (*a*/925, fig. 7*c*; *a*/926, fig. 7*d*). The telson, 32 mm. long (longer than the figure), is straight, broadly ensiform, 6 mm. broad at its base. The stylets, 20 mm. long, are also relatively broad and ensiform or sharp-blade-like. They all seem to have once been faintly fluted and ridged or costulated. They were from Leintwardine (Lower Ludlow).

Two similar specimens, collected by the late Mr. Lightbody in Upper-Ludlow beds, 'above Ashley Moor,' are in the Owens College Museum, Manchester. One of the sets, however, has the stylets nearly as long as the style: whether this was due to variation of growth or to accident, we cannot now decide.

B. M. '39404,' from Leintwardine, belongs to the same species, though the style is rather longer (35 mm.).

Also M. P. G. $\frac{1}{17}$ ('Catal.' 1878, p. 142), from Leintwardine, seems to belong to this form. It shows two segments and appendages. Style, 40 mm.; one stylet present, broad and ensiform, 25 mm. long.

Specimen A, Oxford Mus. (Grindrod Coll.) consists of the penultimate (11 mm.), and ultimate (20 mm.) segments, with a broad style (45 mm.) and corresponding smaller stylet (25 mm.), of what seems to be a rather large *C. robusta*. The caudal spines are strong, broad, and ensiform, the style

is fluted; the stylet flat, except its marginal rims. The two segments are neatly ornamented with imbricate lozenge-shaped or sharp leaf-like lines, each angle inclosing a smaller leaf-like lattice-work, as in Barrande's *C. Scharyi*. This is in the Lower-Ludlow olive-grey laminated mudstone from near Ludlow with an Orthoceras.

Another in the same Coll. (H), from the same series, consists of four segments (35 mm., the ultimate being 15 mm.), with style (32 mm.) and a stylet (18 mm.). These spines are ensiform and broad; the stylet flat with edge-rims, the style ridged and pitted (= spinose, two lines visible). The segments are ornamented as in specimen A, but with a smaller pattern, and the penultimate and two higher segments have lateral oblique lines coming down from the angular lines which covered the back.

Two other specimens in the same Collection, from the Upper (?) Ludlow, correspond more closely with M'Coy's specimens, being short trifid sets of broad spines—one (T) with a style 28 mm. long and stylets each 15 mm., the other (S) having style 23 mm. and stylets 13 mm. In both the stylets are smooth with slight marginal rims, and the style is faintly fluted and pitted (= spinose), in T definitely along two rows, one near each margin.

Var. longa.

Specimen Ludlow Museum M. is a broad and much longer telson (at least 75 mm. long), with linear ornament, from the Lower Ludlow at Bow Bridge, Ludlow. A small part of a slightly curved ensiform stylet shows from beneath it. This may be either a variety of *C. robusta*, or possibly a distinct species.

14. CERATIOCARIS, *sp. nov.*?

In Owens College Museum, Manchester, is a very delicate little set of caudal appendages. The style (central) shows a circular section at its base (top), about 2 mm. wide, is 12 mm. long, and tapers gently to a sharp point. The lateral stylets are 8 mm. each. All are delicately ridged and fluted. From the Lower-Ludlow or Aymestry Limestone, on the old road at Mocktree; collected by the late Mr. Lightbody.

Mus. Pract. Geol. D $\frac{22}{14}$ ('Catal. C. S. Foss.' 1878, p. 118), from the Lower Ludlow at Leintwardine, is a somewhat similar little set of appendages (three spines). The middle one is the longest, 8 mm., the others 6 mm.

These may belong to a very young condition of some of the species above mentioned, or possibly to a distinct species.

In the British Museum one of those marked '58878' from Linburn, near Muirkirk, shows a style (21 mm.), tapering, with circular section at base, and apparently smooth, together with a corresponding attached stylet, 16 mm. long. Were these not smooth, they might be referred to the same species as the foregoing smaller specimens. This set differs from the appendages of either *C. papilio* or *C. stygia*.

15. CERATIOCARIS DECORA, Phillips.

1848. *Onchus decorus*, Phillips. Mem. Geol. Surv.' vol. ii. part 1, p. 226, pl. 30, figs. 5, 5*a*.
1867. *Ceratiocaris decorus*, Salter. In 'Siluria,' 3rd (4th) edit. p. 516.
1877. " " H. Woodward. 'Cat. Brit. Foss. Crust.' p. 70.

This is a small obscure style (?), 13 mm. long, from the Ludlow beds, of Freshwater-East, Pembrokeshire.

B. *Doubtful Genera.*

16. Ceratiocaris (?) ensis, Salter.

1860. *Ceratiocaris? ensis,* Salter. 'Ann. Mag. N. H.' ser. 3, vol. v. p. 159.
1867. „ „ „ In 'Siluria,' 3rd edit. p. 516.
1877. „ „ H. Woodward. 'Catal. Brit. Foss. Crust.' p. 71.

In the Grindrod Collection, Oxford Museum, specimen O, we find the original fossil described by Mr. Salter in 1860, namely, a large telson, nearly 6 inches long, lying on its side and flattened, bulbous at its base, sword-shaped, with an incurved apex, a crenatoserrate convex dorsal margin, and flat sides with sub-central lateral rib (originally lozenge-shaped in section). From the Lower Ludlow at Leintwardine, near Ludlow. Not quite perfect at point, it is 145 mm. long; 16 mm. broad at the bulb, and 13 mm. below it. We have to add that along and close to the inner (concave) edge there is a multiple row of pits (= small spines or prickles), in threes and fours obliquely set, along the upper half, below the bulbous portion; and these die out downwards in a less regular, thinner, and more scattered series. Casts of parasitic Polyzoa (?) cover the bulb and occur here and there on the spine. The arrangement of the pitting along the concave edge may indicate a distinct *generic* relationship. It reminds us of Barrande's *C. debilis*, as figured in his 'Sil. Syst. Bohême,' vol. i. Suppl. pl. 18, figs. 26–28, and pl. 31, figs. 16–19.

There is another similar but much less distinct specimen, in the same Collection, from near Ludlow.

17. Ceratiocaris (?) lata, Salter.

1866. *Hymenocaris? latus,* Salter. 'Mem. Geol. Surv.' vol. iii. p. 240.
1866. *Ceratiocaris? latus,* Salter. Ibid. p. 294, woodcut fig. 5.
1867. „ „ „ In 'Siluria,' 3rd (4th) edit. p. 516.
1873. „ „ „ 'Cat. Camb. Sil. Foss.' p. 16.
1877. „ „ H. Woodward. 'Cat. Brit. Foss. Crust.' p. 71.

The specimen is in the Cambridge Museum (*b*/299 ?), and shows 5 (?) abdominal segments crushed endwise, so as to be shortened (12 mm.) and widened (28 mm.). The woodcut referred to is a *restoration*. The specific, and even generic, relationship is obscure. From the Tremadoc Slate, at Garth, east of Portmadoc; collected by Mr. D. Homfray.

18. Ceratiocaris (?) insperata, Salter.

1866. *Ceratiocaris? insperatus,* Salter. 'Mem. Geol. Surv.' vol. iii. p. 295.
1867. „ „ „ In 'Siluria,' 3rd (4th) edit. p. 516.
1873. „ „ „ 'Cat. C. S. Foss.' p. 16.
1877. „ „ H. Woodward. 'Cat. B. F. Crust.' p. 71.

In the Cambridge Museum (A/275). Obscure remnant of an ultimate abdominal segment, with clear indications of a trifid appendage; the telson or central spine seems to be the longest, but all three are broken off above their points. The telson is about 35 mm. long. From dark-grey shales between the Lower and Upper Tremadoc Slates in a railway-cutting above the village of Penmorfa, Portmadoc. Collected by Mr. D. Homfray. Mr. Salter thought that it belonged to the same species as the foregoing.

19. CERATIOCARIS (?).

An obscure hinder moiety (25 × 12 mm.) of a carapace possibly referable to *Ceratiocaris*, is in the Mus. Pract. Geol. $\frac{13}{84}$, 'Catal. C. S. Foss.' 1878, p. 72. From the 'Upper Llandovery; Onny River.'

20. CERATIOCARIS ? PERORNATA, Salter.

1878. *Ceratiocaris perornatus* (Salter MS.), Huxley and Etheridge. 'Catal. Camb. Sil. Foss.' M. P. G. p. 142.

Very little is known of this obscure form. One specimen M.P.G. x $\frac{1}{11}$, and two in the Cambridge Museum, are only fragments (one rather more than an inch long, and the others less) of what seem to be cylindrical spines (like those of Echinoderms), about 5 mm. in diameter, two pitted all over (?) and one tuberculate. They are from the Upper Ludlow of Benson Knot, near Kendal, Westmoreland.

C. *Genera distinct from Ceratiocaris.*

21. CERATIOCARIS ? ELLIPTICA, M'Coy.

1849. *Ceratiocaris ellipticus*, M'Coy. 'Ann. Mag. N. H.' ser. 2, vol. iv. p. 413.
1851. " " " 'Brit. Pal. Foss.' fasc. i. p. 137, pl. 1 E, fig. 8.
1854. " " Morris. 'Catal. Brit. Foss.' 2nd edit. p. 103.
1859. " " Salter. In 'Siluria,' 2nd (3rd) edit. p. 538.
1860. " " " 'Ann. M. N. H.' ser. 3, vol. v. p. 157.
1867. " " " In 'Siluria,' 3rd (4th) edit. p. 516.
1873. " " " 'Catal. Camb. Sil. Foss.' p. 178.
1877. " " H. Woodward. 'Catal. Brit. Foss. Crust.' p. 71.

This interesting species, one of the first two established, is represented in the Cambridge Museum by specimen *b*/15 (M'Coy's fig. 8), and in the Museum of Practical Geology by $\frac{23}{32}$ ('Catal.' 1878, p. 118) and x $\frac{1}{10}$ ('Catal.' p. 142). The carapace is long-ovate in outline, not very convex, greatest convexity of surface and curvature of ventral margin 'at about one-third from the anterior end'; obliquely rounded in front; obliquely truncate at the upper portion of the hinder end. There is a spot like a definite ocular tubercle in the anterior fourth and above the median line of each valve, and this gives it a distant likeness to a guinea-pig's profile. The surface is neatly marked with delicate, longitudinal, parallel lines, rather far apart. The published figure of the specimen, *b*/15 (32 mm. long and 13 mm. high) is reversed, and drawn too angular behind. It came from the Upper-Ludlow sandstone of Benson Knot. Specimen M. P. G. $\frac{23}{32}$ is from the Lower-Ludlow beds of Leintwardine, near Ludlow, and is not quite so large nor so well preserved as *b*/15. Specimen M. P. G. x $\frac{1}{10}$, from the Upper-Ludlow of Combe Wood, Presteign, is larger and more ovate or elliptical than the others, but, unfortunately, is imperfect. The last two have been incorrectly labelled '*C. Murchisoni.*' In 1860 Mr. Salter thought that *C. elliptica* was only a badly preserved variety of *C. inornata* ('A. M. N. H.' *l. c.*), but in the 'Catal. Cambr. Sil. Foss.' p. 178, he recognised it as 'quite distinct.'

The above-mentioned three specimens supply the only evidence of an eye-spot in these British Ceratiocaridoid Phyllopods.[1] It is not only a generic character distinguishing them from *Ceratiocaris*, but an important

[1] The 'ocular tubercles' mentioned in the footnote at p. 236, *Siluria*, 3rd (4th) edit. 1867, are without doubt due to the presence of 'teeth' within the valves.

family distinction, of which, for the present, we do not propose to estimate the value.

22. Physocaris vesica, Salter.

1860. *Ceratiocaris (Physocaris) vesica*, Salter. 'Ann. Mag. N. H.' ser. 3, vol. v. p. 159, woodcut fig.
1865. *Ceratiocaris (Physocaris) vesica*, Salter and H. Woodward. 'Catal. Chart. Foss. Crust.' p. 17, fig. 8.
1867. *Ceratiocaris vesica*, Salter. In 'Siluria,' 3rd (4th) edit. p. 517.
1877. *Ceratiocaris (Physocaris) vesica*, H. Woodward. 'Cat. Brit. Foss. Crust.' p. 72.
1878. *Ceratiocaris vesica*, Huxley and Etheridge. 'Cat. C. S. Foss.' p. 142.

Of this curious fossil Phyllopod, described carefully by Mr. Salter in 1860, only one specimen is known—namely, 'Ludlow Museum U.' It differs slightly from Mr. Salter's figure, being larger, and showing an appearance of having been probably broken away to a little extent just above the front, so as to leave a notch and angle, which constitute the prominence in the woodcut figure. If continued over this notch the outline of the shell would possibly be that of a broad oval; whereas now it is broadly and obliquely pyriform (25×20 mm.). The relative position of the animal is supposed to be indicated by the telson occupying the upper part of the abdominal appendages attached to the fossil. There are 8–9 segments in the abdomen, which appears to come out from the lower and hinder quarter of the carapace, and is very slender near its origin, but higher at its ultimate segment (5 mm. long); altogether 30 mm. The telson itself is 11 mm. long. One lateral spine (stylet), 7 mm., is present. The whole animal is about two inches long.

It was collected by the late Mr. Salwey in the Lower Ludlow at Leintwardine, and Mr. Salter at first registered it as *Ceratiocaris inflata.*

23. Acanthocaris, B. N. Peach.

In the 'Transact. R. Soc. Edinburgh,' vol. xxx. Part I. for 1880–1 (1882) Mr. B. N. Peach gave a memoir 'On some New Crustaceans from the Lower Carboniferous Rocks of Eskdale and Liddesdale; and in Part II. for 1881–2 (1883) his 'Further Researches among the Crustacea and Arachnida of the Carboniferous Rocks of the Scottish Border.' In the first memoir he described and figured his new *Ceratiocaris scorpioides* (p. 73, pl. 7, figs. 1–1*f*), and *C. elongatus*, p. 74, pl. 7, figs. 2–2*f*. In 1883 he instituted a new genus, *Acanthocaris*, for these curious Cuma-like forms, and added a new species, *A. attenuatus* (p. 512, pl. 28, figs. 1–1*e*). *Acanthocaris* has its body much longer than the carapace, which is small, with a blunt snout-like projection in front and rounded postero-ventral side-lobes behind. Two denticulated jaws occur within the carapace near the antero-ventral margin. The total length of the animal from 1 to 2½ inches. It has a much smaller carapace and longer abdomen than *Ceratiocaris*, and the form and structure of the carapace, and the relative size and shape of the segments, are very distinctive. Mr. Peach thus describes the genus:—

'Carapace small and not hinged, produced anteriorly into a blunt snout, and posteriorly into rounded lobes. Body fusiform and long, composed of numerous segments which increase in length backwards, the seven posterior ones being uncovered by the carapace. Third segment from tail tumid and notched on its ventral surface. Telson long and spiniform, and flanked on each side by a rudimentary spinelet. Test smooth or slightly wrinkled, but not striated longitudinally.'

D. *Extra-British Fossil Phyllocarida.*

24. CERATIOCARIS (?) LONGICAUDA, D. Sharpe.

1853. *Dithyrocaris? longicauda*, D. Sharpe. 'Quart. Journ. Geol. Soc.' vol. ix. p. 158, pl. 7, fig. 3.

The ultimate segment and trifid appendage of a small Ceratiocarid of uncertain genus. Except that the central spine or style is the longest of the three, this little fossil might be almost matched with C. E. Beecher's *Elymocaris siliqua*, pl. 2, fig. 1, and p. 13, of his memoir in the 'Report Geol. Surv. Penns.' 1884. The segment (about 8 mm.) is described as 'simple and rounded'; the spines as 'lancet-shaped,' . . . 'the middle one somewhat rounded and twice as long as the lateral plates, which are nearly flat.' . . . 'From the upper division of the Lower Silurian formation at Sazes, in the Serra de Bussaco.' Collected by Senhor Carlos Ribeiro. In the Geological Society's Collection (?).

This set of spines is much stouter than the specimens M. P. G. D $\frac{22}{14}$, and both stouter and shorter than the somewhat similar small set in the Owens Coll. Mus. (See above, p. 350.)

25. CERATIOCARIS DEWEII, Hall.

1852. *Onchus Deweii*, J. Hall. 'Geol. Surv. New York, Palæontology,' vol. ii. p. 320, pl. 71, figs. 1*a*–1*d*.
1859. *Ceratiocaris Deweii*, J. Hall. 'Geol. Surv. N. Y. Pal.' vol. iii. p. 420*.

A fine large telson, 6 inches long, and about 20 mm. wide at its basal joint; gently curved, ridged, and pitted (once spinose); bulbous, with a strong articulation, at its base (figs. 1*a*, 1*b*). Figured with its sharp end upwards.

Also the ultimate segment (fig. 1*c*) of the abdomen, $2\frac{1}{2}$ inches (65 mm.) by about 22 mm. broad (high). Its ornament (fig. 1*d*) consists of imbricating, narrow, lanceolate, low elevations, which are obliquely striated, thus reminding us of the ornamentation of *C. Scharyi*, Barrande, 'Syst. Sil. Bohême,' p. 454, pl. 32, figs. 24–29; and we find similar ornamentation in some British forms.

C. Deweii is from the Niagara Shale (Upper Silurian) of Lockport and Rochester, State of New York.

26 & 27. CERATIOCARIS MACCOYIANA, J. Hall; and C. ACUMINATA, J. Hall.

1859. *Ceratiocaris Maccoyianus*, J. Hall. 'Geol. Surv. N. Y. Pal.' vol. iii. Part I. (text), p. 421*, and Part II. (plates), 1861, pl. 84, figs. 1–5.
1859. *C. acuminatus*, J. Hall. *L. c.* p. 417*, p. 422*, pl. 84, fig. 6, & 7 (?).

These specimens were obtained from the Upper-Silurian Waterlime Group, near Buffalo, New York State.

Fig. 1 (*C. Maccoyiana*) is rather obscure, and reminds us at first sight of an imperfect *C. stygia*, with the body-segments and caudal appendages reversed, so as to emerge from the anterior (broken) part of the carapace.

Fig. 2 has a carapace somewhat like *C. stygia*, modified by pressure, very delicately striate, and with the abdomen reversed to the anteroventral part of the carapace.

Fig. 3 shows two end segments and a trifid appendage, somewhat like those parts in a specimen (from Benson Knot), Cambr. Mus., *b*/6, which we refer with doubt to *C. stygia*.

Fig. 4 is a smaller and less perfect specimen.

Fig. 5 some segments and appendages much like those of some specimens of *C. stygia*.

Fig. 6 (*C. acuminata*) is an elegant carapace, ovately-trapeziform, slightly arched above, fully convex below, with a sloping, ogee, truncate posterior, and an acuminate front sloping rapidly down to the middle of the ventral margin, with its slope nearly parallel to that of the posterior truncation. It is finely striated longitudinally. This is very similar to some relatively narrow forms of *C. stygia*, particularly to Brit. Mus. '41898'; but still the details vary. It may also be compared with some forms of *C. Murchisoni*, such as M. P. G. x $\frac{1}{5}$ and x $\frac{1}{8}$, but not so satisfactorily.

Fig. 7 is a crushed portion of a large carapace, delicately striate on the ventral region, and four (?) crushed abdominal segments. Probably of the same species as fig. 6, as intimated by Prof. Hall (p. 417*).

28. Ceratiocaris aculeata, J. Hall.

1859. *C. aculeatus*, J. Hall. 'Geol. Surv. N. Y. Pal.' vol. iii. Part I. p. 422*; Part II. (plates), 1861, pl. 80 A, fig. 10.

This is apparently an ultimate segment (split), a broad telson (split ?), and one stylet. If so, the telson is 20 mm. long, and 5 mm. broad near its base, and is comparable with *C. robusta*. It is from the Waterlime Group, at Waterville, N. Y.

29. Ceratiocaris Nœtlingi, Fr. Schmidt.

1883. *Ceratiocaris Nötlingi*, Fr. Schmidt. 'Mém. Imp. Acad. Sci. St.-Pétersbourg,' ser. 7, vol. xxxi. p. 84, woodcut fig. 5; pl. 6, figs. 8, 9; pl. 7, fig. 12.

This has an elegant carapace (about 72 × 38 mm.), comparable with some individuals of our *C. Murchisoni* (Salter's '*leptodactylus*'), but not quite agreeing in all details. It is nearly semi-ovate in lateral outline, sharp in front, truncate with neat hollow curve behind. It closely approaches Dr. James Hall's *C. acuminatus*, which, however, is fuller in the ventral margin. The surface is delicately striated longitudinally, concentric with the ventral border; it is bordered ventrally with a thin raised rim.

A fine set of caudal spines (pl. 6, fig. 8) shows a telson (style) 38 mm. long, 11 mm. broad at its base, tapering rather rapidly, and ridged. The main ribs are tuberculate, and a blunt spine stands out on each side below the triangular bulb or base of the telson. One stylet (22 mm.) is rather broad, ensiform, and flat, except a faint median ridge. Fig. 9 is an imperfect style.

From an Upper-Silurian limestone, near Rootziküll, Oesel, in the Baltic.

30. M. Barrande's Species of Ceratiocaris.

The following *Ceratiocarides* have been carefully described and figured by the late M. J. Barrande; and we proceed to point out their most notable features, indicating characters by which they can be compared with the British and other forms.

(1.) Ceratiocaris docens, Barrande.

1856. *Leptonotus Bohemicus*, Barr. 'Parall. entre la Bohême et la Scandinavie,' p. 58.
1865. *Eurypterus*, sp. Barr. 'Défense des Colonies,' vol. iii. p. 235.

1868. *Eurypterus leptonotus*, Barr. Bigsby, 'Thes. Silur.' p. 199.
1872. *C. docens*, Barr. 'Syst. Sil. Bohême,' vol. i. Suppl. p. 450, pl. 21, figs. 32–35.

Seven segments, all somewhat displaced and those at the ends broken, about 80 mm. long altogether. Some are about 20 mm. high. Longitudinal ornament of delicate, interrupted, wrinkly, raised lines of two sizes (fig. 35). This belongs to Barrande's Silurian Stage[1] E e 2.

(2.) CERATIOCARIS DECIPIENS, Barrande.

1865. *Eurypterus*, sp. Barr. 'Déf. des Col.' vol. iii. p. 235.
1872. *C. decipiens*, Barr. 'S. S. B.' vol. i. Suppl. p. 449, pl. 21, figs. 36–38.

Three of the distal segments; the ultimate (longest) broken. Altogether about 35 mm. Much smaller than *C. docens*, stout-looking, subcylindrical or sub-quadrate in cross-section. The ornament is longitudinal, consisting of delicate, wrinkly, raised lines, in fascicules radiating backwards (upwards), fig. 38. This belongs to Stage E e 1. This fossil is so very similar to a *Bactropus* that it will probably be found to belong to one of the Phyllopods allied to *Aristozoe*. See further on, page 359.

(3.) CERATIOCARIS SCHARYI, Barrande.

1872. *C. Scharyi*, Barr. 'S. S. B.' vol. i. Suppl. p. 454, pl. 32, figs. 24–29.
1876. *C. Scharyi*, F. Rœm. 'Leth. geogn.' Th. i. 'Leth. pal.' Expl. pl. 19, fig. 6.

Seven segments (75 mm., ultimate segment 23 mm.). Height of the highest (sixth from the end), 20 mm.; height at the end of the ultimate segment, 10 mm. Proximal portion of the trifid appendage attached in place. Ornamented with a delicate imbrication of raised, leaf-shaped lines, like pointed arches, with a minute tracery of smaller leaf-like pattern within them: all pointing backwards (fig. 27). The same on the basal portion of the telson also. The ornament has some resemblance to the pattern on *Eurypterus*. It occurs also on *C. Deweii*, Hall, and on some British forms. This species belongs to Stage E e 1.

(4.) CERATIOCARIS BOHEMICA, Barrande.

1853. *Ceratiocaris* (*Leptocheles*) *Bohemicus*, Barr. 'Neues Jahrb. für Min.' &c. 1853. Heft iii. p. 342.
1868. *Ceratiocaris Bohemicus*, Barr. Bigsby, 'Thesaur. Silur.' p. 199.
1872. *C. Bohemicus*, Barr. 'Syst. Sil. Bohême,' vol. i. Suppl. p. 447, pl. 19, figs. 1–13.

Ultimate segment (fig. 1), 50 mm. long; with linear longitudinal ornament of interrupted raised lines. Telson ridged, and pitted (= spinose) along two channels on the back; linear ornament (as above) on the base; fragment 130 mm. Stylets (one perfect, 80 mm.), ridged.

Near to *C. Murchisoni*. Several specimens of telsons and stylets are in the Brit. Mus., some marked '44378,' '44428,' and '44383,' and some not numbered. This species belongs to Barrande's Stage E e 2.

[1] Barrande's 'Stages' are—

Third Fauna.—	Stages	H, h 1, 2 G, g 1, 2, 3, 4 F, f 1, 2 E, e 1, 2	= Passage-beds, Ludlow, Wenlock, and Llandovery.
Second Fauna.—	Stages	D, d 1, 2, 3, 4, 5	= Bala-Caradoc, Llandeilo, Lingula-flags, and Menevian.
Primordial Fauna.—	Stages	C, c 1	
Azoic		B A	= Precambrian, &c.

(5.) CERATIOCARIS INÆQUALIS, Barrande.

1868. *Ceratiocaris inæqualis*, Barr. Bigsby, 'Thes. Sil.' p. 199.
1872. „ „ „ 'Syst. Sil. B.' vol. i. Suppl. p. 452, pl. 19, figs. 14–16, 18; and Var. *decurtata*, figs. 17, 19.

Some segments and appendages. Much smaller than *C. Bohemica*. Telson 70 mm. long. Stylets (fig. 18), 30 mm. long; var. *decurtata* has them much shorter. A small crushed individual of this variety (fig. 19) bears the original little prickles along the telson. The lines of the longitudinal ornament are more inosculant than in *C. Bohemica* (fig. 15), and are oblique on a separate segment (fig. 16). The Brit. Mus. has two specimens ('42585'). This species belongs to Barrande's Colony d 5, and Stage E e 1, e 2. The var. to E e 1.

(6.) CERATIOCARIS ?[1] DEBILIS, Barrande.

1868. *Ceratiocaris debilis*, Barr. Bigsby, 'Thes. Sil.' p. 199.
1872. „ „ „ 'Syst. S. B.' vol. i. Suppl. p. 448, pl. 18, figs. 20–25; pl. 19, figs. 20–27; pl. 26, fig. 18; pl. 31, figs. 16–19.

Small, but like *C. Bohemica* in some respects. Only the appendages known. Style subflexuous (50 mm.), smooth on one (inner) face and pitted (= spinose) along two lines on the other (fig. 20). Style and stylets all ridged. A rostrum, probably of this species, narrow, chevron-marked, thin, and 6 mm. long, is shown at pl. 26, fig. 18. Ornamental lines, longitudinal, on the basal end of the telson (pl. 18, fig. 24). The Brit. Mus. has two pieces marked '42586,' in one of which some fragments of a style or stylet (marked *C. debilis*) lie close by a carapace of *Aristozoe perlonga*, Barrande. This species belongs to Barrande's Stage F f 2; *A. perlonga* also belongs to Stage F f 2.

(7.) CERATIOCARIS TARDA, Barrande.

1868. *Ceratiocaris tardus*, Barr. Bigsby, 'Thes. Sil.' p. 199.
1872. „ „ „ 'Syst. S. B.' vol. i. Suppl. p. 455, pl. 18, figs. 26–29.

Fragments of a style or stylet (?) Outer face rounded and smooth; inside channelled on each side of the smoothed and raised middle, with a row of large and small pits (= spines), symmetrically arranged in each channel (fig. 27). This species belongs to Stage G g 1.

(8.) CERATIOCARIS PRIMULA, Barrande.

1868. *Ceratiocaris primulus, imperfectus, et elegans*, Barr. Bigsby, 'Thes. Sil.' p. 199.
1872. „ „ Barr. 'Syst. S. B.' vol. i. Suppl. p. 453, pl. 18, figs. 14–19.

Two styles or stylets (?) only of this interesting form. They are spiniform, curved, and lozenge-shaped in section—that is, having four sloping sides or faces; the front and back edges are sharper than the side edges. The surface is faintly and irregularly ridged, and is pitted all over with the marks of former minute tubercles or spines (figs. 17 and 19). This belongs to Stage D d 5.

M. Barrande has described and figured several specimens of the dentate jaws (or teeth) like those of *Ceratiocaris* and *Dithyrocaris*, at p. 443, pl. 18, figs. 2–5; pl. 21, figs. 41–44; and pl. 31, fig. 21.

It is remarkable that no *Ceratiocaris* is represented by the *carapace* among M. Barrande's very numerous specimens. Some of the more

[1] See further on, p. 359, for O. Novák's remarks on this form in relation to *Bactropus* and *Aristozoe*.

unusual forms of telsons, such as *C. tarda* and *C. primula*, may belong to *Nothozoe* or some of the associated genera. M. O. Novák refers individuals of *C. debilis* to *Aristozoe regina* (see further on). Some also of the toothed mandibles may belong to such genera, as shown by Mr. C. E. Beecher.

31. M. BARRANDE'S ARISTOZOE, OROZOE, CALLIZOE, AND NOTHOZOE.

In 1863 ('Sixteenth Report State Cabinet N. Y.' p. 74) Dr. James Hall referred a certain Devonian Ceratiocarid, with some doubt, to *Aristozoe*, thus intimating a relationship for this genus different to that which Barrande thought of. Hall's species, however, has been since placed in the genus *Echinocaris* by Prof. R. P. Whitfield, who, though he did not regard *Aristozoe* as a Ceratiocaridal Phyllopod, but, with Barrande, as an Ostracod, collocated his *Aristozoe Canadensis* with some species of *Echinocaris* for comparison, in the plate (separate) illustrating his paper in the 'Americ. Journ. Sci.' ser. 3, vol. xix. January 1880. With these facts before us, as supporting our own views on the subject, we inserted the *Aristozoe*, *Orozoe*, and *Callizoe* of Barrande in our *Synopsis of the Genera of Fossil Phyllopods* at p. 217 of 'Brit. Assoc. Rep.' for 1883; and we now add his *Nothozoe* as being probably near to *Ceratiocaris*.

M. Barrande illustrated several species of these genera in his 'Système Silur. Bohême,' vol. i. Suppl. 1872. Some he had already mentioned by name in Dr. Bigsby's 'Thesaur. Siluricus,' 1868, p. 199. The genera were established in 1872.

1. *Aristozoe amica*, 1868, p. 476, pl. 24, figs. 32–39.
   „ *bisulcata*, 1868, p. 477, pl. 23, figs. 9–14.
   „ *inclyta*, 1872, p. 478, pl. 24, figs. 40, 41.
   „ *lepida*, 1872, p. 479, pl. 24, fig. 42; pl. 27, fig. 7; pl. 32, figs. 14, 15.
   „ *memoranda*, 1868, p. 480, pl. 24, figs. 43–51; pl. 27, fig. 6; pl. 32, figs. 16, 17.
   „ *orphana*, 1868, p. 481, pl. 23, figs. 6–8.
   „ *perlonga*, 1868, p. 482, pl. 23, figs. 26–39.
   „ *regina*, 1868, p. 483, pl. 22, figs. 14–23; pl. 27, fig. 5.
   „ (?) *Jonesi*, 1872, p. 478, pl. 25, figs. 9–13.
2. *Orozoe mira*, 1868, p. 537, pl. 24, figs. 23–26; pl. 31, figs. 7–9.
3. *Callizoe Bohemica*, 1868, p. 503, pl. 22, figs. 1–13.
4. *Nothozoe pollens*, 1868, p. 536, pl. 23, figs. 15–21; pl. 27, figs. 1–4.

1. *Aristozoe* has strong convex valves, straight dorsally, variously and often boldly curved downwards and backwards ventrally, with strong ventral rim. Various and usually strong cephalothoracic nodes, comprising tubercles which, marking places of attachment of internal organs, especially those of the buccal region, are usually present. The valves gape; in *A. Jonesi* (which has one feeble node) very widely at both ends. This, probably, is generically distinct. Valves of different species, and of different ages, vary from 10 to 80 mm. in length. The ornament in some is a minute reticulation (fig. 2, pl. 23); in others it is delicately linear (fig. 7*b*, pl. 27).

A. perlonga has persistently a small neat tubercle on the middle of the rim bordering the posterior edge of the valve. The tubercle of the muscle-spot (?) is very strong in this form, and the valves are relatively long and narrow. With one specimen of *A. perlonga* in the British Museum ('42586') a fragment of a thin caudal spine of some Ceratiocarid is closely imbedded. M. O. Novák has found reason to treat of *A. regina* as a Ceratiocarid with abdominal segments and caudal spines. (See further on.)

2. *Orozoe* has the cephalothoracic nodes very strong, and a great blunt spine projecting from the upper part of the posterior moiety of the valve.

3. *Callizoe* is very distinct from the foregoing. It is delicately shaped, long-half-egg-shaped, with straight back, and sometimes a slight inflection of the antero-ventral margin, near which the cephalothoracic nodes are placed, instead of dorsally as in *Aristozoe* and *Orozoe*. The ventral rim distinct and regular; the ornament of the valves delicate, longitudinal, inosculating, raised lines, with an intermediate minute punctation (fig. 7).

4. Barrande's *Nothozoe* is illustrated by seven figures of specimens, mostly ovate or oval, with plain surface; somewhat like *Ceratiocaris*, especially fig. 1, pl. 27. The ventral rim, however, is apparently too strong for that genus in figs. 1 and 2. The specimens measure 28 × 16, 40 × 25, 50 × 30, and 65 × 40 mm.

32. Aristozoe regina, Barrande, *and its abdominal appendages.*

M. Ottomar Novák, the keeper of the Barrande Collection at Prague, has lately made some valuable observations on some of the specimens collected by M. Barrande and referred by him to *Aristozoe*, *Bactropus*, and *Ceratiocaris debilis*. ('Remarques sur le genre *Aristozoe*, Barrande.' 'Sitzungsb. k. böhm. Gesellsch. Wissensch.' 1885.)

M. O. Novák has with great acumen discovered that such a telson as is described for *Ceratiocaris debilis* by Barrande will accurately fit, in all respects, the distal end of one of the fossil abdominal segments, figured and named *Bactropus longipes* by Barrande ('Sil. Syst. Bohême,' vol. i. Suppl. 1872, p. 581, pl. 21, figs. 1–22). Further, he has found that large numbers of individuals of the *Bactropus*, the Ceratiocarid telson, and *Aristozoe regina*, Barr., are associated in the same white limestone of the 'f 2' band over a wide area in Bohemia. Hence he has reason to regard the carapace, the abdominal segment, and the telson as all belonging to one animal. This seems, indeed, to be very likely; but at the same time there are probably more than one species and genus indicated by the telsons referred to *C. debilis*. One, at least (pl. 18, fig. 24), if correctly determined, has a longitudinal linear ornament, not agreeing with that of *Bactropus longipes*, which is transverse (pl. 21, fig. 22; and Novák, *op. cit.* pl. 1, figs. 21–23). M. Barrande found also a characteristic Ceratiocarid 'rostrum' with his *C. debilis* (pl. 26, fig. 18). M. Novák indicates that the structure of the basal joint of the telson would accommodate the hingement of two lateral stylets, so that *Aristozoe* would have had the trifid caudal appendage usual in the *Phyllocarida*. It yet remains to be shown how many were the abdominal segments of which the curious, cylindrical, tubular *Bactropus* was one, and what proportion this long ultimate segment bore to the others. M. Novák refers to it as 'a part of the post-abdomen (several segments? coalesced)'; further research will probably help in its elucidation.

33. Echinocaris and its Allies.

In the 'Geological Magazine,' dec. 3, vol. i. 1884, pp. 393–396, we published some 'Notes on Phyllopodiform Crustaceans referable to the Genus Echinocaris from the Palæozoic Rocks.' In this we mentioned in detail the evidence supplied by the labours of Dr. James Hall and Prof.

R. P. Whitfield for the genus *Echinocaris* and its species, and reproduced illustrative figures from their memoirs, namely:—

'Sixteenth Annual Report State Cab. N. Y.' 1863.

Ceratiocaris armatus, J. Hall, p. 72, pl. 1, figs. 1–3. Hamilton Group, Ontario County, N. Y.

„ *longicaudus*, J. Hall, p. 73, pl. 1, figs. 4–7 (?). Genessee Slate, Ontario County, N. Y.

„ ? *punctatus*, J. Hall, p. 74, pl. 1, fig. 8. Hamilton Group, Cayuga Lake, N. Y.

'Palæont. New York,' vol. v. part 2; 'Illustrations of Devonian Fossils,' &c. 1876.

Ceratiocaris armatus, J. Hall, pl. 23, figs. 4, 5.

„ *punctatus*, J. Hall, pl. 23, fig. 7.

Both of these are referred to one species in the Explanation of the Plate.

'Americ. Journ. Sci.' ser. 3, vol. xix. Jan. 1880.

Echinocaris sublevis, Whitfield, p. 36, figs. 4–6.

„ *pustulosa*, Whitfield, p. 38, fig. 7.

„ *multinodosa*, Whitfield, p. 38, fig. 8.

In separate plate. All from the Erie Shales (Portage and Chemung, at Leroy, Lake County, Ohio).

Echinocaris punctata, Hall. Whitf. p. 37. Carapace.
„ *armata*, Hall. Whitf. p. 37. Abdomen and telson.
} = *E. punctata*, according to Prof. Whitfield.

These two we put together as *E. armata*, 'Geol. Mag.' 1884, p. 393; and we hazarded the opinion that figs. 4, 5, and 6 of pl. 1 (1863) may have belonged to this species, and that certainly fig. 7 was specifically (if not generically) distinct.

Mr. C. E. Beecher, of Albany, has added considerably of late to our knowledge of *Echinocaris* and its allies ('Second Geol. Surv. Pennsylvania: Report of Progress, P.P.P.' 1884). Giving a careful account of the generic characters of this form, and of the specific features of *E. punctata* (Hall), p. 6, pl. 1, figs. 13–16, he adds *E. socialis*, n. sp., p. 10, pl. 1, figs. 1–12; and then describes *Elymocaris siliqua*, nov. gen. et sp., p. 13, pl. 2, figs. 1, 2; *Tropidocaris*, gen. nov., p. 15; *Tr. bicarinata*, n. sp., p. 16, pl. 2, figs. 3–5; *Tr. interrupta*, n. sp., p. 18, pl. 2, fig. 6; and *Tr. alternata*, n. sp., p. 19, pl. 2, figs. 7, 8. Except *E. alternata*, which is from the Waverley Group, the new species are from the Chemung Group, Warren, Pennsylvania. The trifid caudal appendage seems to have had the lateral spines (stylets) of nearly the same length as the central spine (telson or style). He describes also and figures some denticulated mandibles from the Hamilton Group, New York, at p. 9, and pl. 2, figs. 9–11.

We further added a critical note on the *Equisetides Wrightiana*, Dawson, from the Portage Group, New York State, 'Quart. Journ. Geol. Soc.' vol. xxxvii. 1881, p. 301, pl. 12, fig. 10, and pl. 13, fig. 20. We ventured to think we had good proof of this being really a portion of the abdomen (two segments) of a very large *Echinocaris*—*E. Wrightiana* (Dawson). Like the other *Echinocarides*, it was found in the Devonian strata of North America. This interesting relic represents perhaps the largest Ceratiocarid known, each segment being about 2 inches long, 2 inches high, and 1 inch thick.

With *E. armata* (*punctata*) Mr. Beecher finds associated many denticulated mandibles, similar to those found with *Ceratiocaris* in Scotland. Some he refers to that species; others he thinks belonged to an unknown species. Fig. 16 illustrates a pair of mandibles in place, 'nearly one-third the length of the valves'! The carapace of this species measures about 30 × 20 mm. (largest 55 × 37 mm.); there are six external segments, prickly on the back, smooth underneath, 35 mm.; telson, 23 mm.

E. socialis is a very small form, belonging to the same group as Whitfield's species from New York State. It measures 18 × 10 mm.; abdomen, 6 mm.; telson, 6 mm.

Elymocaris has its valves plainer and more oblong than those of *Echinocaris*. The long straight dorsal edge and elliptically curved ventral (deeper behind than in front) give a semi-ovate outline. The posterior is truncate, with a hollow curve just below the postero-dorsal angle. Ocular tubercle distinct, but the other cephalothoracic nodes are less developed than in *Echinocaris*, and occupy the angular anterior third of the valve. The abdomen preserved in fig. 1, pl. 2, shows a penultimate and an ultimate segment (the latter apparently split longitudinally), and a trifid appendage of a stout short telson and two stylets almost as broad and quite as long, 'crenulated along their inner margins for the attachment of fimbria,' as in *Dithyrocaris Neptuni*, Hall, and *D. tricornis*, Scouler. This set of stout small caudal spines and segments will doubtless prove very useful in comparing other but less distinct fossil appendages.

Carapace-valve, 23 × 10 mm.; two segments, 10 mm.; telson, 9 mm.

Tropidocaris has semielliptical valves (25 × 12 mm. and 37 × 14 mm.), very similar in outline to those of *Elymocaris*, but ornamented with 2–7 longitudinal, interrupted, raised, parallel ridges (somewhat analogous to those on some varieties of *Kirkbya permiana* and *K. euglypha*, but more especially to those on some of the species of *Dithyrocaris*). Delicate curved striæ also on some valves. Optic and other nodes present. Abdominal segments small, cylindrical, tapering, not well known.

34. The COLPOCARIS of F. B. Meek is a Carboniferous fossil of much interest, though of doubtful character in some respects.

1868. *Ceratiocaris? sinuatus*, Meek and Worthen. 'Amer. Journ. Sci.' vol. xlvi. p. 22.
1873. *Ceratiocaris? sinuatus*, M. and W. 'Geol. Surv. Illinois' (Geol. and Palæont.), p. 540, fig. 5, woodcut.

Somewhat rhombic-subovate; posterior end truncate and deeply sinuous; dorsal margin a depressed arch. From the Coal-measures, Grundy County, Illinois.

1872. *Colpocaris* (? sub-genus of *Ceratiocaris*) *Bradleyi* and *elytroides*, Meek. 'Proceed. Acad. Nat. Sci. Philada.' vol. xxiv. pp. 332–34.
1875. *Ceratiocaris* (*Colpocaris*) *Bradleyi*, Meek. 'Report Geol. Surv. Ohio,' vol. ii. (Geol. and Palæont.), Part II. 'Palæontology,' p. 318, pl. 18, figs. 6*a*–6*e*.
1875. *Ceratiocaris* (*Colpocaris*) *elytroides*, Meek. *Op. cit.* p. 319, pl. 18, figs. 5*a*, 5*b*.

These are acute-oval, but one end has a relatively large semicircular notch cut into it. The first of these two differs but little, except in the relative depth and slight obliquity of semicircular notch in what is described as the posterior margin. The surface is minutely reticulate (fig. 6*c*). A large and a small individual are figured; 70 × 32 mm., and 24 × 10 mm. Fig. 6*d* indicates a set of three caudal spines, and 6*e*, another set not so perfect. These were found associated with the carapace-valves. Figs. 5*a*, 5*b*, is a small species (28 × 13 mm.) of a generally similar outline; and fig. 5*c* shows its longitudinal linear ornament. These are from the Carboniferous beds of Ohio, U.S. As yet we have no knowledge as to the exact relationship of *Colpocaris*. See also Prof. Whitfield's remarks, 'Americ. Journ. Sci.' vol. xix. 1880, p. 36.

The other Phyllopodous genera mentioned in our lists, such as *Dithyrocaris*, *Estheria*, &c., will be treated of at another opportunity.

Fifth Report of the Committee, consisting of Mr. R. ETHERIDGE, Mr. THOMAS GRAY, *and* Professor JOHN MILNE (*Secretary*), *appointed for the purpose of investigating the Earthquake Phenomena of Japan.* (*Drawn up by the Secretary.*)

ON account of an excursion which I have the intention of making during the coming summer to Australia and New Zealand I am compelled to draw up this report a month earlier than usual. As the only time when the work of attending to observations and experiments repays itself is during the winter months, I may safely say that my intention of shortening the time usually devoted to earthquake observations is not likely to involve any serious loss.

If we refer to the records of the last year—that is to say, from the end of April 1884 to the end of April 1885—it will be seen that the opportunities for making observations have been unusually good. The number of earthquakes felt during corresponding periods in two previous years and this last year was respectively twenty-six, thirty-nine, and eighty.

Not only have the earthquakes been numerous, but some of them have been pretty stiff, as is testified by the fact that on several occasions chimneys fell and walls were cracked.

The work done during the last year is briefly as follows.

Seismic Experiments.

From time to time I have had the honour of reporting to the British Association on seismic experiments. These experiments were commenced in conjunction with Mr. T. Gray in 1880. The movements which were then recorded were produced by allowing a heavy ball, 1,710 lbs. in weight, to fall from various heights up to thirty-five feet. Subsequently many experiments were made by exploding charges of dynamite and gunpowder placed in bore-holes. The observations which were made upon the resultant vibrations of the ground were very numerous. As examples of them may be mentioned—the determination of the nature of earth vibrations as deduced from diagrams, the velocity of propagation of different kinds of vibrations, the relative motion of neighbouring points of ground, experiments on the production of earth currents, experiments on projection and overturning, &c.

During the last year, whilst working up the long series of records which accumulated, several laboratory experiments were made to investigate the methods to be employed when analysing the diagrams of earth motion.

The first of these experiments consisted in projecting a small ball from the top of a tall flat vertically-placed spring, and at the same time causing the spring to draw a diagram of its motion. From the distance the ball was thrown its initial velocity could be calculated. From the diagram, either by calculation on the assumption of simple harmonic motion or by direct measurement, the maximum velocity of movement could be obtained.

These three quantities practically agreed. The most important result obtained by these experiments was that they indicated an important element to be calculated in earthquake or dynamite diagrams, and, further

that in these diagrams the first sudden movement, which invariably has the appearance of a quarter-oscillation, ought apparently to be considered as a semi-oscillation.

The second set of experiments consisted in determining the quantity to be calculated from an earthquake diagram which would give a measure of the overturning or shattering power of a disturbance.

For this purpose a light strip of wood was caused by means of a strong spiral spring and a heavy weight to move horizontally back and forth with the period of the spring. On this strip small columns of wood were stood on end, and it was determined how far the spring had to be deflected and then suddenly released to cause overturning.

Knowing the period of the spring and its amplitude, the maximum velocity v, the meantime acceleration $\frac{v}{t}$, and the maximum acceleration $\frac{v^2}{a}$ might be calculated. An acceleration, f, sufficient to cause overturning could also be calculated from the dimensions of the column. The result of various experiments showed that for small deflections f was nearly equal to $\frac{v}{t}$, but for larger deflections the value for f lies between $\frac{v}{t}$ and $\frac{v^2}{a}$. From this it seems that the overturning power of an earthquake can only be approximately determined from the dimensions of a body which has been overthrown. The quantity f is not the quantity v, or 'maximum velocity of an earth particle,' so largely employed by Mallet and other earthquake investigators. Such a quantity, which may be determined for bodies of definite dimensions on the assumption that they are overturned by a *sudden blow*, so far as my experiments have gone, does not tell us anything about the nature of earthquake motion.

An account of these and other experiments which I have from time to time been engaged upon will shortly be published as a part of Vol. VIII. in the 'Transactions of the Seismological Society.' The more important results of all these experiments are as follows.

In reading these conclusions it must be remembered that they only refer to experiments performed in certain kinds of ground.

I. *Effect of Ground on Vibration.*

1. Hills have but little effect in stopping vibrations.
2. Excavations exert considerable influence in stopping vibrations.
3. In soft damp ground it is easy to produce vibrations of large amplitude and considerable duration.
4. In loose dry ground an explosion of dynamite yields a disturbance of large amplitude but of short duration.
5. In soft rock it is difficult to produce a disturbance the amplitude of which is sufficiently great to be recorded on an ordinary seismograph.

II. *General Character of Motion.*

1. The pointer of a seismograph with a single index first moves in a normal direction, after which it is suddenly deflected, and the resulting diagram yields a figure partially dependent on the relative phases of the normal and transverse motion. These phases are in turn dependent upon the distance of the seismograph from the origin.

2. A bracket seismograph indicating normal motion at a given station commences its indications before a similar seismograph arranged to write transverse motion.

3. If the diagrams yielded by two such seismographs be compounded, they yield figures containing loops and other irregularities not unlike the figures yielded by the seismograph with the single index.

4. Near to an origin, the first movement will be in a straight line outwards from the origin; subsequently the motion may be elliptical, like a figure 8, and irregular. The general direction of motion is, however, normal.

5. Two points of ground only a few feet apart may not synchronise in their motions.

6. Earthquake motion is probably not a simple harmonic motion.

III. *Normal Motion.*

1. Near to an origin the first motion is outwards. At a distance from an origin the first motion may be inwards.

As to whether it will be inwards or outwards is probably partly dependent on the intensity of the initial disturbance, and on the distance of the observing station from the origin.

2. At stations near the origin the motion inwards is greater than the motion outwards. At a distance the inwards and outwards motion are practically equal.

3. At a station near the origin, the second or third wave is usually the largest, after which the motion dies down very rapidly in its amplitude, the motion inwards decreasing more rapidly than the motion outwards.

4. Roughly speaking, the amplitude of normal motion is inversely as the distance from the origin.

5. At a station near an origin the period of the waves is at first short. It becomes longer as the disturbance dies out.

6. The semi-oscillations inwards are described more rapidly than those outwards.

7. As a disturbance radiates the period increases. Finally it becomes equal to the period of the transverse motion. From this it may be inferred that the greater the initial disturbance the greater the frequency of waves.

8. Certain of the inward motions of 'shock' have the appearance of having been described in less than no time.

9. Tables have been calculated to show the maximum velocity of normal motion.

10. Diagrams have been drawn to show the intensity of normal motion.

11. The first outwards motion, which on diagrams has the appearance of a quarter-wave, must be regarded as a semi-oscillation.

12. The waves on the diagrams taken at different stations do not correspond.

13. At a station near the origin, a notch in the crest of a wave of shock gradually increases as the disturbance spreads, so that at a second station the wave with a notch has split up into two waves.

14. Near the origin the normal motion has a definite commencement. At a distance the motion commences irregularly, the maximum motion being reached gradually.

IV. *Transverse Motion.*

1. Near to an origin the transverse motion commences definitely but irregularly.

2. Like the normal motion, the first two or three movements are decided, and their amplitude slightly exceeds that of those which follow.

3. The amplitude of transverse motion as the disturbance radiates decreases at a slower rate than that of the normal motion.

4. As a disturbance dies out at any particular station the period decreases.

5. As a disturbance radiates the period increases. This is equivalent to an increase in period as the intensity of the initial disturbance increases.

6. As we recede from an origin the commencement of the transverse motion becomes more indefinite.

7. It will be observed that the laws governing the transverse motion are practically identical with those which govern the normal motion, the only difference being that in the case of normal motion they are more clearly pronounced.

V. *Relation of Normal to Transverse Motion.*

1. Near to an origin the amplitude of normal motion is much greater than that of the transverse motion.

2. As the disturbance radiates, the amplitude of the transverse motion decreases at a slower rate than that of the normal motion, so that at a certain distance they may be equal to each other.

3. Near to an origin the period of the transverse motion may be double that of the normal motion; but as the disturbance dies out at any given station, or as it radiates, the periods of these two sets of vibrations approach each other.

VI. *Maximum Velocity and Intensity of Movement.*

1. An earth particle usually reaches its maximum velocity during the first inward movement. A high velocity is, however, sometimes attained in the first outward semi-oscillation.

2. The intensity of an earthquake is best measured by its destructive power in overturning, shattering, or projecting various bodies.

3. The value $v^2 = \frac{4}{3} g \sqrt{a^2 + b^2} \times \left(\frac{1 - \cos\theta}{\cos^2\theta} \right)$ used by Mallet and other seismologists to express the velocity of shock as determined from the dimensions of a body which has been overturned, is a quantity not obtainable from an earthquake diagram. It represents the effect of a sudden impulse.

4. In an earthquake a body is overturned or shattered by an acceleration, f, which quantity is calculable for a body of definite dimensions.

The quantity f as obtained from an earthquake diagram lies between $\frac{v}{t}$ and $\frac{v^2}{a}$, where v is the maximum velocity, t is the quarter-period, and a is the amplitude.

5. The initial velocity given in the formula $v^2 = \frac{2\ a^2}{b}$ (for horizontal projection), used by Mallet as identical with v^2 in 3, is not an identical quantity.

The velocity calculated from the range of projection when projection occurs is identical with the maximum velocity as measured directly or calculated from a diagram.

6. In discussing the intensity of movement I have used the values $\frac{v^2}{a}$.

7. The intensity of an earthquake at first decreases rapidly as the disturbance radiates; subsequently it decreases more slowly.

8. A curve of intensities deduced from observations at a sufficient number of stations would furnish the means of approximately calculating an absolute value for the intensity of an earthquake.

VII. *Vertical Motion.*

1. In soft ground vertical motion appears to be a free surface wave which outraces the horizontal component of motion.

2. Vertical motion commences with small rapid vibrations, and ends with vibrations which are long and slow.

3. High velocities of transit may be obtained by the observation of this component of motion. It is possibly an explanation of the preliminary tremors of an earthquake and the sound phenomenon.

4. The amplitude and period of vertical waves as observed at the same or different stations have been measured.

VIII. *Velocity.*

1. The velocity of transit decreases as a disturbance radiates.

2. Near to an origin the velocity of transit varies with the intensity of the initial disturbance.

3. In different kinds of ground, with different intensities of initial disturbance, and with different systems of observation, I determined velocities lying between 630 and about 200 feet per second. Mallet determined a velocity in sand of 824 feet, and in granite of 1,664 feet, per second. General Abbot has observed velocities of 8,800 feet per second. All of these determinations I regard as being practically correct, the great difference between them being due partly to the nature of the rock, the intensity of the initial disturbance, and the kind of wave which was observed.

4. In my experiments the vertical free surface wave had the quickest rate of transit, the normal being next, and the transverse motion being the slowest.

5. The rate at which the normal motion outraces the transverse motion is not constant.

6. As the amplitude and period of the normal motion approach in value to those of the transverse motion, so do the velocities of transit of these motions approach each other.

7. By cross-bending and torsion of cylinders of rocks the velocity with which normal and transverse vibrations would be propagated in such rocks has been determined. These determinations show that the

ratio of the speed of these two kinds of motion is not constant. The softer and less elastic rocks are, the nearer do these velocities approach each other. That the ratio of the speed of normal and transverse motions is not constant is shown from a table of these velocities calculated for different rocks from their moduli of elasticity.

IX. *Miscellaneous.*

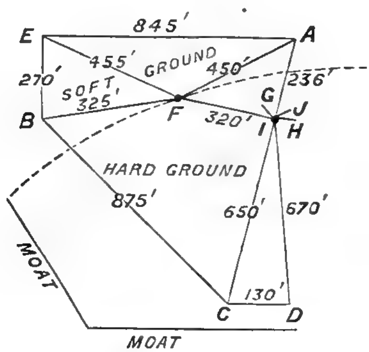
1. At the time of an earth disturbance, currents are produced in telegraph lines.
2. The exceedingly rapid decrease in the intensity of a disturbance in the immediate neighbourhood of the epicentrum has been illustrated by a diagram.
3. For the duration of a disturbance due to a given impulse in different kinds of ground, reference must be made to the detailed descriptions of the first four sets of experiments.

X. *The Simultaneous Observation of Earthquakes at several Stations in Electrical Connection.*

In my last report to the Association I gave the results of observations carried on at three stations, which were indicated by the numerals I., II., and III. These three stations I now call A, B, and C, and have added on to them other stations in the same area called D, E, F, G, H, and J.

G refers to the records taken by an instrument placed inside a house specially constructed to mitigate the effects of earthquake motion. H is a station in a pit 10 feet deep. To these records I shall make special reference. J is a station where there are now two instruments. It is between the house and the pit, about 20 or 30 feet from each. F is a station on the edge of flat marshy ground, at the foot of a slope running nearly north and south. At a level of about 10 feet above this are the stations C and D on hard ground. The relative position of these stations will be understood from the following sketch (fig. 1). A line from A to

Fig. 1.



B bears S 15° 30′ W. The dotted line shows a gentle slope dividing the soft ground from the hard ground. The softest ground is in the middle of the triangle B, E, F, where it is quite marshy. The following five tables embody the principal results which have been obtained. For stations G, H, and J the number of observations are too few to give average results. I is the starting station.

The analysis of the diagrams from which the above tables have been calculated has not yet been completed. Some of the more important results to which they point are as follows:—

1. All stations have invariably given different records for the same earthquake. The principal differences relate to direction, period, amplitude, maximum velocity, and maximum acceleration.

2. On the hard ground, as at C and D, the amount of motion is very much less than at the remaining stations, like A, B, F, and E. Comparing together the average maximum velocities and maximum accelerations at C and E, we see that they have respectively been as 1 to 5 and 1 to 2·4. A practical conclusion to be drawn from this is that a house at C might stand whilst a similar house at E might be shattered.

3. Similar waves only appear in the diagrams at different stations where an earthquake is strong.

4. As a disturbance passes from station to station the time interval between two similar waves suffers a change. This leads to uncertainty in determining the velocity with which a disturbance travels.

Other results to be derived from these observations will be given at a future period. In the tables of the report upon stations A, B, and C, published in 1884, several misprints occurred. These are now corrected.

Experiments on a Building to resist Earthquake Motion.

In the report of last year I described a house which rested at its foundations upon cast-iron balls. These balls were 10-inch shells. The records obtained from an instrument placed inside this house showed that, although it was subjected to considerable movement at the time of an earthquake, all *sudden* motion had been destroyed. Although the balls did very much to mitigate earthquake motion, wind and other causes produced movements of a far more serious nature than the earthquake. To give greater steadiness to the house, 8-inch balls were tried, and then 1-inch balls. Finally the house was rested at each of its piers upon a handful of cast-iron shot, each $\frac{1}{4}$ inch in diameter. By this means the building has been rendered astatic, and, in consequence of the great increase in rolling friction, sufficiently stable to resist all effects like those of wind. The shot rest between flat iron plates. That the house had peculiar foundations would not be noticed unless specially pointed out. The motion experienced in the house is indicated in column G of the preceding tables. The best idea of this motion is seen by reference to the accompanying diagram, taken on February 12, 1885. From this diagram it will be seen that in the house only two small shocks, A and B, were recorded, whilst at all the other stations, not only were there many shocks equivalent to A and B, but there were many which were greater. From these experiments it seems evident that it is possible to build light one-storied structures of wood or iron in which, relatively to other houses, but little movement will be felt.

Observations in a Pit 10 *feet deep.*

The instrument placed in this pit is similar to all the other instruments, and is installed in a similar position. Column H in the preceding tables refers to the observations which have been made. Comparing the

maximum amplitudes, maximum velocities, and maximum accelerations obtained in the pit with those obtained at about thirty feet distance at station J, they are for one particular earthquake respectively in the ratios of 1 : 43, 1 : 52, and 1 : 82 (see diagram for March 20, 1885).[1] In most earthquakes the extent of motion has been too small to admit of measurement, and that there had been any movement could only be detected by holding the plate on which the record was written up to the light and glancing along it lengthways. This investigation tends to confirm the view which I have previously put forward, that an earthquake at a short distance from its epicentrum is practically a surface disturbance, principally consisting of horizontal movements. The vertical motion is small, and is best seen in the preliminary tremors either of an actual earthquake or of a dynamite explosion. From a practical point of view these results must be of the greatest importance to those who have to erect heavy structures in earthquake districts. At a future time I hope to continue these experiments by comparing together the motion—1st, of a foundation unattached to the sides of the excavation where it is built; 2nd, of a similar foundation connected to the sides by brushwood and covered with a layer of earth; 3rd, of a similar foundation put in the ground in the ordinary method; 4th, of a piece of ground isolated with trenches; and 5th, of the ordinary ground.

Buildings in Earthquake Countries.

As during the last few years so much destruction both to life and property has taken place in various parts of Europe, it seems that an epitome of the results of observations and experiments carried on in Japan relative to construction in seismic districts might not only be interesting, but possibly it might also be of practical value. When erecting a building it appears that we ought first to reduce as far as possible the quantity of motion which ordinary buildings receive; and, second, to construct a building that it will resist that portion of the momentum which we are unable to keep out. To reduce the momentum which usually reaches a building the following may be done:—

1. Institute a seismic survey of the district or area in which it is intended to build, and select a site where experiment shows that the motion is relatively small.

2. For heavy buildings adopt deep foundations (perhaps with lateral freedom), or at least let the building be founded on the hardest and most solid ground. It is perhaps because the tops of the hills in Tokio are harder than the plains that they have relatively the least motion. To what extent a building may be isolated by trenches or natural valleys is not yet known, but it must be remembered that a building only *partially* isolated may be exceedingly dangerous from the fact that motion entering in the unprotected side will make the excavations (cuttings, valleys, &c.) upon the opposite side into free surfaces which will swing forward through a range greater than they would have swung had the excavations not existed.

3. For light buildings, especially if erected on soft ground, where the range of motion is always great, if the structure rests on layers of fine cast-iron shot, it cannot possibly receive the same momentum as a build-

[1] I am not yet prepared to state whether these ratios will hold for all earthquakes.

ing attached to the moving ground. The extent to which the acquisition of momentum may be avoided by the adoption of one or all of these methods may be judged of by reference to the three previous sections of this report. To resist the effects of momentum which cannot be cut off a building, and therefore tends to shatter it, the following rules appear to be among the most important:—

1. Bear in mind the fact that it is chiefly stresses and strains which are applied horizontally to a building which have to be encountered. Ordinary masonry arches are continually cracked by earthquakes, inasmuch as they are only designed to resist the stresses due to gravity. Iron or wooden lintels, or at least tie-rods, may be used to strengthen or replace such arches. Arches which meet these abutments at an angle are more liable to be cracked than those which meet them with a curve. A vertical line of openings like doors or windows in a building constitute a vertical line of weakness to horizontally-applied forces.

2. Avoid coupling together two portions of a building which have different vibrational periods, or which from their position are not likely to synchronise in their motion. If such parts of a building must of necessity be joined, let them be so joined that the connecting link will force them to vibrate as a whole, and yet resist fracture.

Brick chimneys in contact with the framing of a wooden roof are apt to be shorn off at the point where they pass through the roof. Light archways connecting heavy piers will be cracked at the crown. To obviate destruction due to these causes a system of construction similar to that to be seen in several of the buildings of San Francisco, Tokio, and Yokohama may be adopted. This essentially consists of tieing the building together at each floor with iron and steel tie-rods crossing each other from back to front and from side to side. In connection with this subject I may mention that experiments have shown that in strong earthquakes the abutments of heavy archways approach and recede from each other, cracks in buildings open and shut, other cracks grow longer, and finally that two points of ground not ten feet apart do not synchronise in their motion. These facts show that the assumption of a difference in vibrational phase in parts of a building shaken by an earthquake is not simply an assumption made to explain certain often-repeated observations.

3. Keep the centre of inertia of a building or its parts as low as possible. Heavy tops to chimneys, heavy copings, and balustrades on walls and towers, heavy roofs and the like are all sources of danger to the portion of the structure by which they are supported. When the lower part of a building is moved, the upper part by its inertia tending to remain behind often results in serious fractures. All the chimneys in Tokio and Yokohama which have fallen in consequence of their ornamental heads have been replaced by shorter and thicker chimneys without the usual coping. The roof of a portion of the Engineering College rests loosely on its walls, and has therefore a certain freedom. In Manila many heavy roofs have been replaced by roofs of sheet iron. Walls may be lightened in their upper parts by the use of hollow bricks. Such vertical motion as may exist is also partly obviated by light superstructures. Vertically-placed iron tie-rods give additional security.

If these and other rules which are the result of experiment and observation could be adopted in earthquake countries, it is certain that the loss of life and property might be greatly diminished. Before building

to withstand the effects of earthquake motion it is necessary that the constructor should clearly understand the nature of earthquake motion. If an earthquake is regarded as a sudden blow, and we adopt rules and formulæ founded on this supposition such as are to be found in many of the older treatises on this subject, it seems certain that the success of our undertakings must inevitably be attended with uncertainty.

Earth Tremors and Earth Pulsations.

From time to time reference has been made in reports to this Association to the various methods employed to record earth tremors and earth pulsations. Many of the observations made with delicate spirit levels have now been plotted. The most complete set were those made at the Meteorological Observatory under the direction of Mr. Arai Ikunosuke. The observations were made every three hours both night and day. Although a special column was built for the instalment of these levels, and they were protected so far as possible from changes in temperatures, the bubbles of these instruments wandered to and fro in a manner difficult to explain. M. d'Abbadie, writing to me on this subject, remarks that two levels may be placed parallel and yet the bubbles may move in opposite directions.

Notwithstanding the untrustworthiness of level observations, they nevertheless have given results of interest. These are as follows:—

1. The fact that the bubbles from time to time move back and forth without apparent reason. Considerable changes have sometimes been observed before an earthquake.

2. The greatest movement of the bubble of a level takes place during the colder part of the year, which is the season of earthquakes, and also the season when the barometric gradient between Siberia and the Pacific is the steepest.

3. The bubble of a level continues to move long after the sensible motion of an earthquake has ceased, enabling us to study the slow movements which bring an earthquake to a close.

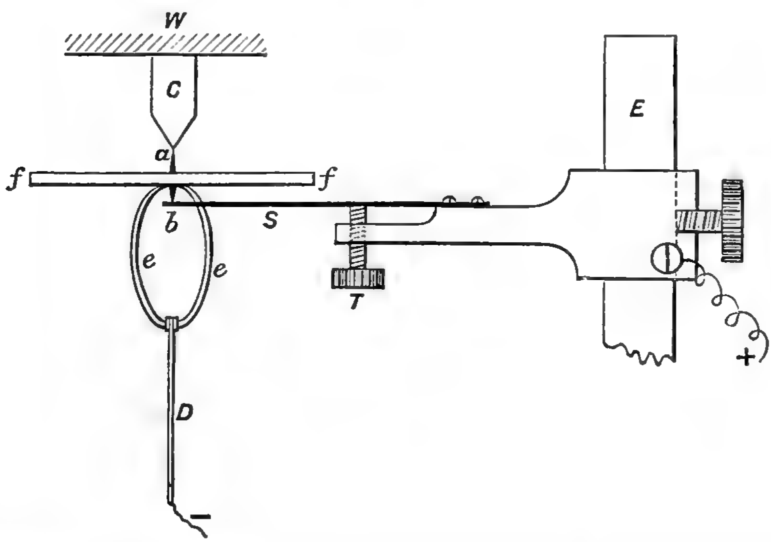
4. When the barometer is very low, as, for instance, during a typhoon, the bubble of a level may be distinctly seen to pulsate back and forth through a range of about ·5 mm.

In addition to the fact that levels are so sensitive to changes of temperature, they have, in common with all other instruments with which I am acquainted, the objections that their changes between the times of observation are unknown. For a long time I experimented to obtain an instrument which would give an automatic record of earth tremors and earth pulsations. After many failures I think that I have at last succeeded in obtaining such an instrument. It is simple, cheap, and exceedingly easy to manipulate. M. d'Abbadie tells me that it has many points in common with an instrument employed by M. Boquet de la Grye. It is briefly as follows. From a circular cast-iron bed plate resting on three levelling screws, there rises a tripod of angle iron about 5 feet high. From the top of this hangs a pendulum, consisting of a thin iron wire and a heavy bob. At the base of this bob, W, there is a small projection C (see fig. 2). As the bob and the projection were turned in a lathe, the extremity of C, which is flat, the centre of figure of the bob and the point where the supporting wire is attached are in one vertical line. Below this bob there is an indicating pointer, *a*, *b*, *c*, *d*, the full length of which is

not shown. *a* and *b* are needle points. The lower point *b* rests on a flat spring, S, which can be raised or lowered by the screw T connected with a solid stand E. By raising *b* the point *a* is brought into contact with the end of C. *f f* is a lead disc nearly sufficient to balance the portion of the pointer below *b*.

The result of this arrangement is that if *a* is moved relatively to *b*, this movement is magnified at the end of the pointer D. The sensitiveness of the instrument may be judged of from the fact that the pressure of my finger on the side of a stone column 2 feet square and 5 feet high is shown by a deflection of 4 or 5 millimetres at the end of the pointer. On the relief of pressure the pointer returns to its central position. To

FIG. 2.



obtain records, at intervals of every five minutes the current from an induction coil is sent down the pointer D, from which it passes as a spark through two strips of paper moving at right angles over the surface of a brass plate. One strip of paper moves north and south, and the other east and west. In this way a magnified representation of the position of the pendulum, drawn as a series of holes, is obtained. The magnification is about seventy times. Every hour a long contact makes a large hole.

As a check to the observations two slightly different instruments are worked simultaneously by the same current, these instruments being on different columns in rooms about 60 or 80 feet apart.

Thus far the results have not been analysed, but the following facts are clear :—

1. Sometimes for days both instruments give a continuous series of holes in a straight line.

2. Sometimes the holes are so multiplied by the trembling of the pointer that a broad line of holes is obtained. These tremors last from 2 to 10 hours.

3. Sometimes the pointer has slowly moved from side to side, giving a clearly defined set of holes marking two or three waves. The amplitudes of their waves, as shown on the diagram, are from 1 to 4 or 5 mm.

Their period varies from 15 to 60 minutes. In these records, which may possibly mean tips of the soil, the two instruments only occasionally agree.

4. Earthquakes are clearly shown by the pointer swinging about and making a series of holes up to the edges of the bands of paper. The relation, if there be any, between these various movements I have not yet determined. As the instrument is simple and inexpensive and satisfactory in its working, I am anxious that it should be brought to the notice of all who are interested in these observations. In connection with these observations I may mention that in September of last year, in conjunction with Mr. W. Wilson, C.E., and Mr. Mano, of the Imperial College of Engineering, I carried one of these instruments to the summit of Fujiyama, which is about 12,365 feet in height. Whilst on the top we were unable to undress, wash, or eat anything but the plainest of food. These and other discomforts, amongst which were the difficulties of breathing, prevented our remaining on the mountain for more than five days.

During this time we obtained observations during the day and night extending over a period of three days. These observations were made by observing the position of the end of the pointer as it moved across a scale of millimetres. The instrument was installed on the top of a very large block of lava, deeply buried in ashes, in the corner of a stone hut in which we slept. It was covered with a wooden case. Outside of this there was a tent made of oiled paper. The instrument was, therefore, well protected against currents of air. Before commencing readings the weight was suspended for about fifteen hours by the same wire on which it had hung for many weeks when in Tokio. To test the effects of moisture in the instrument, at the end of the observations I poured a large quantity of water all round the block of lava forming the support. This produced no visible change in the reading of the instrument.

The scale from which the readings were made, and which was immediately below the end of the pointer, was a piece of metal on which there were a series of concentric circles at intervals of a millimetre. A series of straight lines crossing the centre of these circles gave the points of the compass. Had the scale been a series of lines at right angles to each other, the readings would have been more definite. The results of interest connected with these observations are:—

1. That the movements on the top of the mountain were much greater than those which I usually observe in Tokio.

2. The tremors, or slight swing-like movements of the instrument, did not necessarily accompany the wind.

3. That during the heavy south and south-east gales the direction of displacement of the pointer was towards the south-east, which is the same result as would be obtained if the bed plate of the instrument were raised on the south-east side, or if the mountain had tipped over to the north-west.

My colleague, Mr. T. Alexander, treating Fuji as a conical solid made of brick, with a wind load of 50 lbs. on the square foot, found the slope and deflection of a point 100 feet below the apex of the cone. This calculated slope was two or three times greater than the greatest deflection which I measured.

As it is difficult to imagine that a mountain could suffer deflection by a wind pressure, I will not insist upon the fact that deflection actually

occurred. It is certainly curious that the results of calculation and observation should point in the same direction.

If the observed movements of the pendulum were due to a tip of the mountain, they might equally well have been observed as its base.

The actual observations are given in the following tables :—

1884. Day	Hour	Temperature Fahr.	Barometer	Pendulum	Direction from starting	Remarks
August 12	10.0 A.M.	50°	19·02	0·50	N.W.	Almost still
	11.45	50	19·02	0·50	N.W.	Slow swing from 0 to 1 on N. S. line
	12.30	51	18·97	1·00	NN.W.	Still
	1.0 P.M.	51		0·00		Now and then a slight motion. Temp. in sun 92° F.
	3.0	53	18·97	1·00	S.E.	Slight swing in N.E. and N. quadrant from 0 to ·5
	4.0	50	18·95	3·00	S.E.	Slight movement. Strong wind W. to S.
	6.0	48	18·95	4·00	S.E.	,, ,, ,,
	7.30	46	18·95	4·20	S.E.	Slight movement. Outside temp. 6° C. = 42° F.
	9.0	46	18·90	3·00	S.E.	Slight movement. Strong S. wind
	10.0	46	18·95	3·00	S.E.	Very slight motion. Strong S. gale
August 13	0.45 A.M.	46	18·95	2·00	S.E.	Slight motion. Strong S. gale
	4.30	42	18·92	1·50	SS.E.	Slight motion. Swings from 1 to 2·5 S.E. to S. Strong gale
	8.0	45	18·92	2·50	S.E.	Swings 2 to 3 N. and S. South wind. Gale abating
	9.30	45°	18·92	1·50		Swing 1 to 2 in the E. and N.E. quadrant. Mist and rain. S. wind

	9.30	45	19·00	5·00		Slight motion E.S.E. quadrant. Wind dropping
	11.30	44	18·95	5·00		Swing 4·5 to 5·5 in E.S.E. quadrant. W. wind strong
August 15	1.0 A.M.	42	18·90	5·25		Swing 5 to 5·5. Strong W. wind and fog
	3.45	42	18·93	4·50		Swing 4 to 5. Strong W. wind and fog
	7.0	44	18·90	4·00		Nearly still. Strong S.W. wind and fog
	8.0	44	18·94	4·00		Slight movement. Wind dropped. Heavy fog
	9.0	44	18·94	4·00		In E.S.E. quadrant still. S. wind gentle

After this last observation a quantity of water was poured round the foundation, and during the next hour several observations were made, but no change in reading could be detected.

All the thermometer readings are about 1·5° too high, and the barometer readings ·068 too high. Although none of the temperature readings indicate freezing, water in the doorway of the hut was several times thinly covered with ice. Under the boards on which we slept there was a thick bed of ice, and in the adjoining crater, about 600 feet deep, there were large beds of snow.

Earth Temperatures.

In January a bore-hole was sunk in the grounds of the Imperial College of Engineering, about 100 feet in depth. The section was approximately as follows:—

Earthy materials and sand	78·0 shaku
Very hard gravel	2·5 „
Fine gravel	2·0 „
Sand	6·5 „
Gravel	10·5 „
Taff (a soft clay-like rock)	4·5 „
Total	104·0 „

The feet given are Japanese shaku (shaku = feet). On February 17, a series of thermo-electric junctions were lowered down the hole, one near the bottom, one at approximately 75 feet, another at approximately 50 feet, and a fourth at 21 feet. The bore-hole was then filled up by slowly pouring in from day to day a mixture of clay, sand, and water. The junctions consisted of thick iron and copper wires dipping into a glass tube filled with mercury. All the copper elements had distinct cables leading to the surface. The iron elements at the different stations were joined to a single iron wire leading from the bottom to the top of the hole. The glass tubes were protected by brass tubes. All these junctions, together with a fifth junction buried just below the surface of the ground, can be compared with a similar junction in a water-bath in the Physical Laboratory. The whole of these arrangements are under the charge of Professor Fujioka, who at some future time will probably give some detailed account of his observations. The first records were made on March 26 and ran along steadily until April 16, when, for causes which are unknown, there was suddenly an increase in current, to balance which the water-bath had to be raised to a temperature about double that which had been required a few hours previously.

The first portion of the observations are as follows:—

		T. 25	T. 50	T. 75	T. 100
March 26	2.40 P.M.	15°·0 C.	16°·4 C.	17°·8 C.	18°·00 C.

Eleventh Report of the Committee, consisting of Professor E. HULL, Dr. H. W. CROSSKEY, Captain DOUGLAS GALTON, Professors J. PRESTWICH *and* G. A. LEBOUR, *and* Messrs. JAMES GLAISHER, E. B. MARTEN, G. H. MORTON, JAMES PARKER, W. PENGELLY, JAMES PLANT, I. ROBERTS, FOX-STRANGWAYS, T. S. STOOKE, G. J. SYMONS, W. TOPLEY, TYLDEN-WRIGHT, E. WETHERED, W. WHITAKER, *and* C. E. DE RANCE (*Secretary*), *appointed for the purpose of investigating the Circulation of Underground Waters in the Permeable Formations of England and Wales, and the Quantity and Character of the Water supplied to various Towns and Districts from these Formations. Drawn up by* C. E. DE RANCE.

YOUR Committee have not been able to include in the present report information which would be of considerable value in drawing up a final report on the result of their twelve years' labour. They therefore consider they will best carry out the instructions which you gave them in 1874 by continuing their investigations for another year. That this should be done is the more important from the fact that the present dry season, following the dry summer and autumn of last year, has, by drying up surface springs, and by the diminution of streams, exhibited the importance of the deeper-seated underground stores, but at the same time, has shown that, in estimating the quantities of water to be derived from such sources, it is of the highest importance to obtain data as to the yield of deep wells and borings in years of drought, and to obtain accurate knowledge of the extent of the depression of the level of underground waters. Your Committee had hoped that observations made in the United States or in Canada on the filtering powers of sandstones, the influence of barometric pressure and other changes on the height of underground waters, and on the influence of earthquakes, might have been obtained, but they regret that no such communications have been received.

Mr. C. E. Peek, F.R.Met.Soc., of Rousdon Observatory, three miles west of Lyme Regis, has offered to carry out observations on his well, which is 200 feet in depth and 500 feet above the sea, as regards temperature and changes of level due to alteration of atmospheric pressure or astronomical causes. Mr. I. Roberts, F.G.S., of Maghull, has continued his observations in this direction, but prefers to communicate them as an independent paper to the Royal Society of London. Mr. Roberts's experiments on the action of sandstone in extracting the salts of saline solutions, published as an appendix to the Underground Water Report presented at Dublin in 1878, have been attacked by Mr. William Ripley Nichols, Memb. Boston (U.S.) Soc. of C.E.,[1] who considers 'that the salt solution placed on top of the block forced before it the water already contained in the pores of the stone, and mixed with it but little. . . . If the stone had been perfectly dry there would have been no effect observed, unless, as is the case with most sandstones, the rock actually contained some salt to start with, in which case the first portion of the liquid that came through would contain a trifle more salt than the subsequent

[1] *Journal of the Association of Engineering Societies*, 1884, vol. iii. p. 144.

portions.' In reply, Mr. Roberts writes, 'I would immediately have set to work to verify the results which I had obtained seven years ago; but after studying Mr. Ripley's methods of research, and his inferences, I do not find that he has proceeded on lines that are even approximately reliable as tests of my results.' He asks, 'Is it proof, or reasonable inference, that, because Ohio stone, which contains salt in its pores, does not filter salt from water, neither, therefore, does Triassic sandstone, which does not contain salt, from Everton [Lancashire], filter any?'

It is therefore necessary for Mr. Ripley, to establish his position, to repeat his experiments with sandstones which either contain no salt or from which it has been totally removed. He gives no record of such an experiment in his paper, and Mr. Roberts's experiments remain unassailed.

Mr. Roberts draws attention to the *hygroscopic* properties of the New Red Sandstone, or its power of rapidly absorbing moisture from the atmosphere and giving it off again on any increase of temperature. Four years ago he selected a cube of Bunter sandstone, and depriving it of moisture, weighed it, and found the weight 14,553 grains. This weight he adopted as zero. On exposing the stone freely to the air it rapidly and steadily absorbs moisture, varying from hour to hour with the changes in the humidity. In June, 1883, its weight of moisture varied between 38 and 74 grains, in December of that year it varied between 73 and 107 grains.

Details of Wells and Borings, Berkshire.

Swindon Local Board Well. Mr. R. W. Mylne, C.E., F.R.S., Engineer; Mr. R. Spellor, Blackfriars, London, Contractor. Works consist of a 6-feet shaft of 110 feet depth, with boring to 500 feet below the top of the shaft; at the bottom of the shaft is a chamber of 14 feet, from which is driven an adit level to the side of the hill, tapping the water met with at the bottom of the shaft.

Details and Specimens collected by C. E. De Rance.

From surface feet			Thickness feet
107.	Chalk		107
110.	Sand (upper greensand)		3
248.	Grey clay (gault)		138
250.	Grit (lower greensand?)		2?
322.	Grey clays, harder 310 feet from surface	72 feet	250
500.	Shelly clays (boring discontinued)	178 "	
			500

Comparing these thicknesses with those given in the Horizontal Section of the Geological Survey traversing this area, it is probable that the 250 feet of clay below the grit all belong to the Kimmeridge clay.

	Geological Survey feet	Swindon Section feet
Upper greensand	60	3
Gault	140	138
Lower greensand	40	2?
Kimmeridge clay	280	250
Coral rag	40	
Oxford clay	500	

Denbighshire, N. Wales.

Boring on the London and North-Western Railway, Foryd, near Rhyl, Collected by C. E. De Rance, per Mr. A. Strahan, F.G.S., from Mr. Leigh Howell, of Bagillt.

Lincolnshire Wells and Borings.

Grimsby Waterworks Co. Wells.

Collected by C. E. De Rance from Messrs. Mather and Platt.

Boring west of Grimsby.

From surface ft.	in.		Thickness ft.	in.
21	0	1. Very soft clay, full of vegetable matter	21	0
24	6	2. Gravel and sand	3	6
29	6	3. Clay	5	0
31	6	4. Rough gravel and small flints	2	0
33	6	5. Fine soft clay and small flints	2	0
45	0	6. Rough gravel	11	6
60	0	7. Fine gravel	15	0
75	0	8. Chalk, very hard. Water then rose to 4 feet above the surface in large volume	15	0
			75	0

Boring east of Grimsby, near Cleethorpes.

From surface ft.	in.		Thickness ft.	in.
84	0	Stiff bluish clay, with flakes of chalk	84	0
99	0	Sand and gravel	15	0
224	0	Chalk, with flints in beds	125	0
			224	0

In the Cleethorpes boring the top of the chalk was very rotten, and had to be tubed out down to 120 feet from the surface, or 21 feet from the top of the chalk. The yield from this boring is only about 180,000 to 192,000 gallons per day; but it is evident that the water is not tubed out from the upper part of the chalk, or not entirely so, from the fact that, when this quantity is pumped, the water-level being 24 feet from the surface, the neighbouring wells and bore-holes, none of which do more than penetrate the top bed of the chalk, all lose their supply of water.

At Grimsby Docks there is a well in the chalk 300 feet deep; the water is clear and palatable. Analysed by the Rivers Pollution Commission, was found to have a hardness of 22·1, of which 7·6 was permanent; chlorine was 5·00, in parts per 100,000.

From Mr. John Bennett, Goole, per H. Franklin Parsons, M.D., F.G.S. Section of Trial Boring at Reedness, five miles east of Goole, made by the late Mr. Egremont in 1835.

930	10	59. Red sandstone	20	2
931	10	60. Dark red bind	1	0
955	10	61. Red sandstone	24	0
957	1	62. Dark red bind	1	3
995	4	63. Red sandstone	38	3
998	4	64. Light red sandstone	3	0
1029	0	65. Red sandstone	30	8
			1029	0

In abstract, the section will stand as follows:—

		ft.	in.
Beds 1 to 14.	Drift	69	8
Beds 15 to 43.	Keuper marls with hard bands and gypsum	272	2
Bed 44.	Red sandstone	169	6
Beds 45 to 47.	Red sandstone with 5½ feet of red 'binds'	22	0
Bed 48.	Red sandstone	233	6
Beds 49 to 62.	Red sandstone, with 16 feet 4 inches of red 'binds'	190	3
Beds 63 to 65.	Red sandstone	71	11
		1029	0

Out of 687 feet 2 inches of beds beneath the Keuper marls, only 21 feet 10 inches consists of red binds, the rest being 665 feet 4 inches of red sandstone of similar physical character from top to bottom. They have been referred by Dr. Parsons to the Bunter.

In considering their age and character, it may be useful to compare this section with the borings for salt in the Middlesbrough district, especially that at Saltholm Farm, on the Durham side of the Tees ('Sixth Report Underground Water'). I there suggest that 'the limestones, thick salt beds, and gypsum are probably referable to the Permian; the intervening beds of red sandstone, 832 feet, are probably referable to the waterstones and lower mottled Bunter, the Upper Mottled and Pebble Beds having thinned out.' From more extended investigation, I think it more probable that the pebbly character of the middle portion of the Bunter has died away northwards, and that the Middlesbrough section represents Waterstones, pebbleless Middle Bunter and Lower Bunter.

In the Lincolnshire area some sections collected by Dr. Parsons throw light on this inquiry. He describes the beds below the Keuper marls, in the surface sections as 'a loose red sand, or friable semi-coherent red sandstone, often micaceous, with more coherent clayey bands, and with occasional partings, or pockets of red, green, or yellow ochrey marl.' [1]

Trial Boring for Water, Booth Ferry Road, Goole, made by Goole and Hook Parochial Sanitary Committee in 1876. From Mr. Tudor, Surveyor, Goole, per Dr. Parsons.

From surface ft.	in.		Thickness ft.	in.
17	0	Warp, peat, and clay	17	0
25	0	Rough gravel	8	0
28	0	Warp clay, with a large pebble	3	0
34	0	Red sand	6	0
58	0	Hard, coarse, light red sand	24	0
68	0	Red marl	10	0
79	0	Hard sand	11	0
82	0	Red marl	3	0
108	0	Hard sand	26	0
109	0	Red marl	1	0
170	0	Hard sand	61	0
173	0	Red marl	3	0
176	0	Hard coarse sandstone, with small pebbles	3	0
260	0	Red sandstone and marl mixed	84	0
282	0	Red sand	22	0
284	2	Stiff red marl	2	2
306	3	Marl and red sand	22	1
366	0	Red sandy marl	59	9
			366	0

In abstract, this section gives drift probably 28 feet, red sand 338 feet, of which 19 feet were marl, if the red sandy marl last penetrated be omitted, which added gives an entire thickness of marl of just 80 feet. The occurrence of the small pebbles at 176 feet and the thick marl are worthy of note in this section, and differ from those adjacent; they are probably referable to the Waterstones.

C. E. De Rance, from Dr. Helliwell, per Dr. Parsons. Well deepened in 1876. Helliwell's Brewery, Rawcliffe.

From surface ft.	in.			Thickness ft.	in.
18	0	1.	Old well	18	0

170	0	Red marly *sand*	37	0
173	0	Blue marl	3	0
175	0	Red marl	2	0
263	0	Red marly *sand*	88	0
265	0	Variegated marl	2	0
309	0	Red marly *sand*	44	0
329	0	Coarse red *sand*	20	0
377	0	Red marly *sand*	48	0
379	0	Variegated marl	2	0
403	0	Red marly *sand*	24	0
404	0	Variegated marl	1	0
500	0	Red marly *sand*	96	0
			500	0

This section gives, in abstract, drifts probably 51 feet, and 449 feet of red sandstone, red sand, and coarse red sand, with 11 feet of intercalated marls, the whole of which may be regarded as one series, and compare well with the Goole section, and may be referred to the Keuper waterstones, and might for their important thickness be called the *Goole beds.*

It may be well to reproduce the section of the Selby Waterworks, obtained from Mr. Wetherill by Professor Green, F.G.S.

Surface level $20\frac{1}{2}$ feet above Ordnance datum; the water out of a 6-inch bore-hole rises to 16 feet above Ordnance datum.

From surface ft.	in.		Thickness ft.	n.
5	0	1. Alluvial soil	5	0
29	0	2. Clay	24	0
30	0	3. Sand charged with water that one man could pump	1	0
54	0	4. Clay	24	0
75	0	5. Quicksand. Strong spring of water at base	21	0
		6. Red sandstone	18	0
93	0	7. Marl, resembling 'fullers' earth'	0	1

From surface ft.	in.		Thickness ft.	in.
		8. Red sandstone	10	3
103	3	9. Grey sandstone	0	1
		10. Red sandstone	64	9
		11. Red hard sandstone	118	6
		12. Very hard rock	10	6
		13. Red sandstone	6	9
		14. Very hard rock	4	9
330	8	15. Hard rock	22	0
			330	8

Here there was 75 feet of drift, all the remainder being more or less hard red sandstone, without the intercalated marl beds observable in the Goole section, which are presumably above those penetrated at Selby, which may be referred to the Pebble Beds.

Boring at Donington, on west side of River Bain. Communicated by Mr. Edward Bogg, to the Geol. Soc., London, 'Trans. Geol. Soc.' 1816

	ft.	in
1. Clay soil	3	0

41. Hard, dark, compact shale, like 38	22	10
	309	0

The whole of the above boring appears to be in the Kimmeridge clay.

Mr. Dickenson, F.G.S., in H.M. Inspector of Mines Report for 1881, describes a boring, 1,140 feet deep, put down west of Horncastle, at a point situated on the Kimmeridge clay, near the base of the Cretaceous rocks, which was carried to a depth of 1,140 feet, and is stated to have reached the Triassic sandstones, in which a brine spring was discovered. In this case the Kimmeridge clay, Lower Oolites, Lias, Rhætic, and Keuper marls must have been penetrated.

At Stamford a futile boring for coal was put down by the late Marquis of Exeter to a depth of 500 feet, which, commencing at a similar geological horizon to the two last described borings, failed to reach the base of the Lias at that depth.

A boring at Boston Market Place has already been described in the Report for 1878; some further details communicated to the Royal Society may be found in the 'Phil. Trans.' vol. lxxvii. The well was sunk in 1747 to a depth of 186 feet, and deepened in 1783 to its present depth of 478 feet.

Details of Cores brought up by Diamond Boring Company at Scarle, nine miles S.W. of Lincoln, near boundary of parishes of Scarle and Swinderby, and about 100 *yards from the Lincoln and Nottingham Railway. By Professor Hull, F.R.S.*

	Permian	400	0			
	Carboniferous . .	130	0			
		2030	0			

Mr. Dalton, F.G.S., late of the Geological Survey of England and Wales, has given some different thicknesses as the result of his examination of the cores which he has had the opportunity of inspecting, his alternative figures are given in the second column above. He refers to this boring as the Collingham boring, and regards the locality as a centre of subsidence in Triassic times, and considers the beds there to be of abnormal thickness.

Yorkshire Coal Measures.—The following information as to the thickness of the intercalated sandstones, in the Yorkshire Coal-measures, and their water-bearing capacity, which is of considerable value both as to quantity and quality, have been obtained from Professor Green, M.A., F.G.S., of the Leeds University.

The 'Oakenshaw' or 'Clifton' rock is generally a massive false-bedded sandstone, much divided by joints; it is close in grain and gritty in texture; it furnishes an excellent and durable building stone. In some districts it is separated into two beds; in this case the upper bed is called the 'Shertcliffe Bed Seatstones.' In the Clifton district the two beds, with intervening shales, together form the 'Clifton rock.'

The 'Thornhill rock,' the most important middle coal-measure sandstone in the northern part of the field, is the chief source of building-stone in the district; it is generally close grained and thin bedded, but is sometimes coarse; in places it is much traversed by vertical joints. It occurs below the *Haigh Moor coal*, and also bears the names of the Dewsbury Bank, Morley, Middleton, Robin Hood, and Oulton rock; below it is the *Joan coal.*

'Parkgate rock,' 'Croppergate,' or 'Birstall rock' occurs above the Parkgate coal. At Scholes Colliery it is 80 feet thick; at the Nunnery sinking 90 feet; at the old Pits Moor Collieries it is nearly 170 feet, where it is thickest; it is thickly bedded, rather coarse, and much jointed, and yields abundance of water, necessitating heavy pumping to work the coal when there is no intervening bind above the seam, as is sometimes the case. It is largely quarried at the village of Bradgate, and hence William Smith called it the 'Bradgate rock.'

The 'Woolley Edge rock' is believed to have been deposited in an area bounded by a line running west between Pontefract and Castleford,

by Normanton, a little beyond Wakefield; then south by Woolley Edge, and passing west of Barnsley, ranging S.E., to Hemingfield. To the S.W. it is coarse; at Wakefield finer.

The 'Woolley Edge rock' at Hemingfield, at Lundhill Colliery, consisted of 82 feet 6 inches of sandstone, 23 feet 5 inches of shale, and 24 feet 4 inches of sandstone, overlying the *Wathwood coal*. At Wombwell Main it was 120 feet 2 inches, and 12 feet 5 inches of shale intervened between it and the *Wathwood coal*. North of Dillington it contains pebbles as large as a hazel nut. East of Wakefield, at Whitwell Main Colliery, it lies above the *Wakefield coal*; 38 feet of it is described as 'bleeding rock,' exuding much acrid water, that blisters the hands of the sinkers.

The 'Oaks rock' is so called at Barnsley; at Trenton and the district S.E. of Sheffield it is called the 'Trenton rock.' It can be traced on its outcrop as far as Heath; east of Wakefield it appears to thin away along a line running roughly north-west and south-east through Normanton. It usually carries a large quantity of water—when it is split up with shales the quantity is less; it is largely quarried for building-stone and making grindstones, the most important quarry being near Barnsley. When this rock attains its full thickness it is estimated to be 100 feet, and its base to be 850 feet above the *Barnsley coal*. At Wath Main Colliery the total thickness of rock was 55 yards; it yielded an enormous quantity of water, one feeder alone yielding 3,000 gallons per minute after the tubing was in the shaft, but before it was fully 'wedged' the yield for months was 18,000 gallons per minute.

The 'Pontefract rock' is water-bearing.

Drought of 1884.

Mr. G. J. Symons, F.R.S., finding that the small rainfall of the year had had considerable effect upon the level of water in wells, &c., invited his staff of 2,600 unpaid observers to report any facts within their own knowledge bearing on this question. The following notes are the result of his inquiries:—

South-Eastern Counties.

Reigate.—Shallow wells wholly failed; springs and watercourses had not begun to run at the close of the year.

Tenterden, Summerhill.—River Rother was nearly dry; wells and ponds were nearly all dried up.

Tunbridge Wells.—Springs and wells very low, many dried up.

Maidstone, Lower Tovil.—The Loose stream dry. River Medway very low, and water very clear.

Sheldwick Vicarage.—Springs very low to end of year; water in well 170 feet deep—4 feet below average.

Sevenoaks.—Springs low in autumn; average flow not restored at end of the year.

Wrotham.—Two wells in chalk, 100 feet deep, were dry in autumn, and continued so at the end of the year.

Ospringe, Lorenden.—Strong spring from chalk hills, flowing 4 inches deep in a 4-feet channel, entirely stopped.

Chichester, Westgate.—Surface wells dry; deep chalk wells low.

Midhurst, Cocking.—September to November, water lower than

before in memory of oldest inhabitant. Miller on stream from South Downs could only work one hour in twenty-four in November.

Horsham.—Shallow wells dry north of the town, on the anticlinal axis of the weald, at 245 feet above Ordnance datum. The supply at the waterworks was not affected: surface of well 177 feet above Ordnance datum; depth of well 75 feet, bore hole, 45 feet; total 120 feet, or 57 feet above Ordnance datum. The railway station well, within 90 feet of Ordnance datum, was not affected.

Falmer.—Wells dry in November; rose slightly in December. Springs very low at end of the year.

Lewes, Iford.—Wells, springs, and streams very low.

Warbleton Rectory.—Wells mostly dry in autumn.

Newick.—Many wells failed for first time.

Uckfield.—Driest year since 1858; heavy rain of September relieved drought, but the underground springs did not commence flowing until the continuous rains of December.

East Grinstead.—Many wells dry for first time.

Sandown, Isle of Wight.—Carisbroke Castle well, 240 feet, with an average of 70 feet of water in it, was dried up, it is reported, for the first time since 140 years.

Emsworth, Redlands.—Wells, springs, and streams ran dry; never dry before in 'memory of man.'

Alresford, Ovington.—High Downs wells failed.

East Worldham.—Wells 83 feet deep failed for first time; one 84 feet deep yielded a little water that could be pumped in a few minutes. Spring below the hill held out.

Micheldever, Northbrook.—The level of water in the chalk fell in autumn to a lower point than has been noted since 1870, and, though rising slightly in consequence of the December rainfall, was much below the midwinter average at the close of the year.

Andover, Red Rice.—Many wells dry. Mill and millstream lower than they have been for thirty years.

Rotherwick, Tylney Hall.—Wells dry; springs very low.

Blackwater, Hurstleigh.—Wells and streams very low.

Heckfield, Park Corner.—Driest of thirteen years. Wells failed on November 28, but began to fill November 30.

Newbury, Greenham.—Well for three months 10 feet below its average level, but was restored to normal level by end of year.

Hungerford, Dunford Park.—Springs never seen so low.

Lambourne.—The stream of the Lambourne river ceased running on October 13, and on the 19th the bed of the river (chalk) was dry. In December several wells dried up, and so continued to end of year.

Long Wittenham.—Driest year since 1874. Well 40 feet deep in greensand, 4 feet 6 inches lower than in 1883, and lower than it had been since 1871. Observations have been taken regularly since 1868. Wells in the gravel ran dry.

South-Midland Counties.

Watford, Wansford House.—Driest year since 1874. Deep chalk wells but little affected.

Royston.—Driest year since 1864; springs very low.

Thame, Aston Rowant.—Wells dry in September. Springs lower at end of year than for ten years previously.

Oxford.—Wells dry for first time in living memory.

Stanton St. John.—Springs very low at end of year.

Banbury.—Shallow wells and surface springs dry.

Oundle.—Shallow wells dry. New well carried to 70 feet without meeting with water.

Bedford.—Percolation (by Dalton gauge) through 2 feet 6 inches of soil of medium water-holding power, 5·93 inches.

Tempsford Hall.—Rivers and well all very low.

Cambridge, Fulbourn Asylum.—Water in well sank 4 inches, but supply plentiful.

Eastern Counties.

Leyton Observatory.—Ponds in Epping Forest dry for first time in twenty years.

Chelmsford.—Smallest rainfall since 1868. Many wells failed.

Dunmow.—Wells failed for first time.

Ipswich.—Underground water low, but no wells failed as in 1868. Rainfall one fourth less than the average.

Bury St. Edmunds.—Deep chalk well, the water was 6 feet below the average level.

South-Western Counties.

Maiden Bradley—In October and November, well water very short; some ran dry.

Trowbridge, Steeple Ashton.—Wells reduced in level at end of year; some exhausted.

Pewsey.—Some wells exhausted; all reduced.

Bishop's Cannings.—Well at Shepherd's Shore, which supplies Devizes, is 123 feet deep, with a 12-inch bore-hole, 25 feet lower; the water level at the beginning of the year was 63 feet from the surface, and fell to 96 feet at the end of the year. In 1880 the well was lowered 13 feet, and the bore-hole made, but the water had then never been so low as in 1884.

Mildenhall.—Driest autumn since 1856. Springs at Christmas lower than ever known, and still getting weaker, though the ponds were well supplied by rain of December.

Broad Hinton.—Wells on the Downs dry at the end of November.

Weymouth, Langton Herring.—Many wells exhausted for the first time.

Wimborne Minster, Chalbury.—Rainfall 4·14 inches below the average of twenty years.

Kingsbridge.—Springs failed for first time in memory of man; in many instances had not risen at end of year.

Kingsteignton.—Least rainfall of ten years. Wells deficient for five months.

Collumpton.—Well of 30 feet depth dry for first time.

St. Austell, Trevarna.—Wells dry for first time. Stream in adit driven into a high hill, that taps a spring 210 feet below the surface to supply Tregorrick, became almost dry.

Maker Vicarage (Devonport).—Wells and springs as low as in 1871; remained so until November 20, when a rise set in, and normal height was reached on November 28, before the heavy rain fell, which was not until December 2.

Bodmin.—Springs lower than for eighty years in November; they recovered about December 8.

Liskeard.—Rainfall 15·25 inches below average of twenty years. Springs failed throughout the district, but recovered in December.

Stratton, Week St. Mary.—Many wells dried up for first time, dry from middle of March to end of November.

Bude.—Springs never so low up to end of November.

Ilminster, White Lackington.—Two perennial springs failed.

Bridgwater, Ashford.—Streams supplying the water-supply were very low, but yielded more than the daily consumption of 200,000 gallons per day, the ordinary summer flow being four million gallons per twenty-four hours.

Kewstoke.—Many wells were dry until December rains.

West-Midland Counties.

Chipping Sudbury, Frampton Cotterell.—Wells were dry up to end of November.

Stroud, Brimscombe Vicarage.—Wells and springs dry for first time for years.

Gloucester, Barnwood.—Wells in gravel very low.

Hampen.—The springs that had already failed did so in October, and did not recover until the end of November.

Cheltenham, Battledown.—Hill streams dry for a long period, and wells supplied from sandbed in village were also dry. Cheltenham reservoirs dry.

St. Devereux, Whitfield.—Springs very low.

Ledbury, Putley Court.—60-feet wells very reduced in October and November; the 40-feet wells almost dry.

Hereford, Burghill.—Springs very low.

Pembridge, Marston.—Wells dry November and December.

Ludlow, Ashford.—Many wells dry in November; River Teme low from March to end of year.

Great Malvern, Madresfield.—Wells 16 to 25 feet deep, through marl subsoil, began to fail in October, and supply was limited to December. River Teme lower than for forty years.

Radway.—Driest year since 1870. Springs very low. Many wells no water until after Christmas.

North-Midland Counties.

Belvoir Castle.—Remarkable disappearance of subsoil water.

Oakham, Greetham.—Springs failed for a month.

Spalding, Pode Hole.—Fen drainage engines were standing still at end of year, and the water in Deeping Fen was allowed to rise to almost summer level to afford a supply for cattle, or in case of fire.

Sleaford, Bloxholm.—Wells 100 feet deep dry for weeks, as were springs and streams.

Horncastle.—Springs were dry that have not been so since 1826, from middle of August to middle of December.

Lincoln, Doddington.—Springs very low.

Alford, Sutton-by-the-Sea.—Streams fed by chalk very low, but wells did not fail.

Louth.—Springs very low; the Blow wells and other overflowing springs at Tetney were very low.

Ulceby, Limber Grange.—A well of 150 feet maintained its supply, but shallow wells dried in August.

Appleby.—Springs and wells low last three months of year.

Nottingham, Strelley Hall.—Driest year since 1874. A well in coal-measures, 45 feet deep, stood as follows:—At beginning of May, 36 feet of water in it; in middle of November, 15 feet of water in it, it being then somewhat higher than a short time before.

Newark, East Stoke.—Deep wells maintained their supplies, shallow wells failed. River Trent very low, May to September.

North-Western Counties.

Lymm.—Several wells dry; a perennial spring ceased running.

Maghull.—At Melling Quarry in pebble beds of Bunter, the surface of the underground waters was, on November 23, 1884, 42·5 inches lower than in 1883, 44 inches lower than in 1882, and 31·5 inches below the level of 1881; other conditions being the same.

Arkholm, Storr's Hall.—Dry August and September caused deficiency in wells, and small streams not to run.

Yorkshire.

Stainborough, Wentworth Castle.—Rainfall 10·17 below average of eight years. Springs very low.

Doncaster, Burghwallis Rectory.—Underground water lower than for seventy years. Well still falling at end of year.

Leeds, Oliver Hill, Horsforth.—Water supply from company failed, only supplied two hours a day to December 21. Water was pumped from water running out of Bramhope Tunnel, N.E. Railway.

Otterburn in Craven.—Traffic stopped on Leeds and Liverpool Canal for want of water; five inches of rain in July was all absorbed by ground, and added nothing to tributaries of Aire.

Hull, Derringham.—Seven months' drought; water supply deficient to end of year.

Wold, Newton.—In 1884, for third time since 1875, the Gypsey spring did not rise.

Masham, Burton House.—Springs failed to end of year.

Scarborough.—Chalk springs supplying the town were but little affected, but surface streams very low.

Northern Counties.

Shotley Bridge, Shotley Park.—Rain of July did not penetrate; springs failed until end of year.

North Shields, Clementhorpe.—Springs low to end of year.

Rothbury.—Springs at Whitton Town dry for three days at beginning of November; never known to fail before.

Cockermouth.—Wells failed in April, June, and November.

Wales and Monmouth.

Llanfrechfa Grange.—Springs very low.

Tredunnock.—Wells dry September to November.

Tredegar.—Water short for town supply, and iron and steel works, June till October.

Aberayron.—Many springs failed.

Llanidloes, Broomcliff.—Many springs dry.

Llandwrog, Glynllivon Park.—Springs dried up till late in autumn.

Llanfairfechan.—Springs disappeared until December, but a 40-feet well held out.

Report of the Committee, consisting of Mr. H. BAUERMAN, Mr. F. W. RUDLER, *and* Dr. H. J. JOHNSTON-LAVIS, *for the Investigation of the Volcanic Phenomena of Vesuvius. Drawn up by* H. J. JOHNSTON-LAVIS, *M.D., F.G.S.* (*Secretary*).

THE Reporter has to state that his work has been greatly hindered by the unfortunate outbreak of cholera in Naples, and the stringent local quarantine measures as a result thereof; these causes, combined with the superstitious fears of the people at seeing any stranger, prevented work on Vesuvius being carried out during the autumn of 1884. Nevertheless, daily observations were made of the variations in the activity of the volcano, of which a careful record has been kept.

All important changes of the crater-plain, and in the cone of eruption, have been photographed; copies of these photographs are exhibited at the meeting. Descriptions of the small eruption of May 2 of 1883 have already been given in 'Nature,' and the results of a microscopical examination of the sides of the remarkable hollow dyke then formed will soon be published. The Naples section of the Italian Alpine Club have generously undertaken to publish a journal of Vesuvius, which will contain reproductions of the photographs exhibited.

The third sheet of the geological map of Vesuvius and Monte Somma (scale 1 : 10,000) has been completed by the Reporter, and is exhibited at the meeting. It required thirty-three field days, not including preliminary knowledge obtained by many excursions during the previous years. The difficulties in the execution of this map have not been so much due to the complexity of geological structure as to the amount of detail necessary. This will be evident when the map is examined, for it will be seen that the gradual progress in the formation of a covering of soil to the lava-streams and the development of vegetation is indicated in no less than six different stages, thus rendering the map of agronomic value. Much care and patience was necessary in tracing out the course of ancient lava-streams now covered by a thick layer of loam. As a large part of the area is covered by habitations and by small gardens enclosed by high walls, each of which was separately visited, much time was spent in the work.

The relationship of the varying activity of a volcano in a Strombolian state to barometric pressure, the lunar tides, and rainfall, cannot but be regarded as important in solving some questions of vulcanology. Instrumental means of measuring such present so many practical difficulties that a scale of activity has been drawn up, which requires only a few minutes to learn, can be practised by any one with good eyesight and moderate intelligence who is within visual range of the volcano, and, above all, requires no further outlay than pen, ink, and paper. The objections will be mentioned after describing the process.

1*st degree.*—A faint red glimmer, above the main vent, interrupted by complete darkness.

2*nd degree.*—The glimmer is continuous, but the ejection reaches hardly above the central crater rim at the most.

3*rd degree.*—Glimmer continuous and well marked; the ejections are distinctly discernible as they rise and then fall on the slopes of the cone of eruption and roll down its slopes.

4*th degree.*—The ejections reach a considerable height, are brilliant, and light up the top of the great cone.

5*th degree.*—Verging on an actual paroxysmal eruption, the ejections are shot up very high, being only very slightly or not at all influenced in their course by a strong wind. Each explosion follows with much rapidity, and corresponds with the 'boati' heard all around the west, south, and south-east slopes of the mountain.

The objections to this method of registering the variations in the activity of a volcano are—

(*a*) Cloud-cap, which may for days cut off the view.

(*b*) After a great eruption, resulting in a deep crater, the changes of activity would be invisible from the neighbourhood of the mountain.

(*c*) It is only applicable after dark, so that usually only one observation a day can be made.

(*d*) Should lava be flowing from a lateral outlet, as is often the case, the level of the fluid in the chimney would vary as the outflow took place with greater or less rapidity, dependent on its blocking the passage more or less.

The Reporter thinks it desirable to introduce a description of this method into the report, so that it may be made use of in the case of other suitable volcanoes.

Report of the Committee, consisting of Mr. W. T. Blanford *and* Mr. J. S. Gardner (*Secretary*), *on the Fossil Plants of the Tertiary and Secondary Beds of the United Kingdom. Drawn up by* Mr. J. S. Gardner, *F.G.S., F.L.S.*

[Plates I., II., & III.]

It may not be out of place to preface our First Report on the British Tertiary Flora with a brief summary of what is known regarding it at the present moment. Such a statement may be the more acceptable, as the subject is one, to promote the study of which the Association has made several grants in past years.

The following list will be found to comprise all the principal works on the British Tertiary Flora down to the year 1880:—

1833–5. Lindley & Hutton's 'Fossil Flora' contains descriptions of two Eocene Cycadaceous cones from the Thanet beds, and other Eocene plants are mentioned (pl. 125, p. 117, pl. 226, p. 189). In 1866 Mr. Carruthers redescribed these, referring them to *Pinus* ('Geological Magazine,' vol. iii. pls. 20, 21, p. 534).

1840. Bowerbank's (incomplete) 'History of the Fossil Fruits and Seeds of the London Clay' appeared, and remains to this day the most important work on our Eocene plants.

1851. The Duke of Argyll and Professor E. Forbes described the fossil leaves from Ardtun Head: nine were thought determinable ('Quart. Journ. Geol. Soc.' vol. vii. p. 103, pls. 2, 3, 4).

1854. Prestwich & Hooker figured several plants from Reading and Counter Hill ('Quart. Journ. Geol. Soc.' vol. x. pp. 88, 163, pl. 4).

1856. De la Harpe described the entire British Eocene Flora, as then known ('Bull. de la Société Vaudoise des Sciences Naturelles,' 1856). This was translated and illustrated in 1862 in the 'Survey Memoir on the Isle of Wight' (pp. 109, &c., pls. 5, 6, 7). About 300 specimens from various collections were brought together, and of species there were 43 determined from Alum Bay, 9 from Reading, 9 from Corfe Castle, 22 from Bournemouth, and 9 from the Upper Eocenes. In all 83 species, exclusive of those from Sheppey: but 23 occur in more than one locality, and the total number is thereby reduced to about 60.

1862. Heer & Pengelly's 'Lignite of Bovey Tracy' ('Phil. Trans.' 1862, part II.) was published 1863, when 50 species were described. In the same year Heer described the Hempstead Flora, 10 species in all ('Quart. Journ. Geol. Soc.' vol. xviii. p. 369).

These comprise all the works of any importance, but a complete list of references is given in the 'Introduction to the Palæontographical Society's Memoir on the British Eocene Flora for the year 1879.' Mr. Baily has, in addition, made several reports to this Association on the Antrim plants, and I have myself written from time to time on the same subjects. Baron von Ettingshausen has also published two lists purporting to be complete enumerations of the species from Sheppey and from Alum Bay. For reasons which will be apparent, I cannot help regretting that these lists were compiled and published; but, nevertheless, I intend as far as possible to retain the names given, though they were unaccompanied by descriptions. Setting these two lists apart for the present, we find the following as the number of species that had been more or less described:—

From the Thanet beds	3
„ the Reading beds	9
„ Sheppey	108
„ Alum Bay, &c.	43
„ Bournemouth (deducting those not peculiar)	11
Bovey Tracy	50
Upper Eocenes	13
Mull	9
Antrim, about	16
Total	262

making a grand total of 262 species, not a tenth part of which, I anticipate, will survive a rigorous examination. This was the state of our knowledge of the subject when, in 1878, I was asked to assist in the preparation of a monograph on the Eocene flora, in conjunction with Baron von Ettingshausen, who was to be responsible for the Palæontological work, while I assisted in translating and otherwise.

Our co-operation did not survive the first volume, for I speedily found that my views as to what were satisfactory data, not only on which to found new species, but to identify old ones, were at variance with the Baron's.

I ventured, however, to take the liberty of revising the species in the first volume before closing it, and then intimated to my friend Professor Wiltshire that, if desired, I would endeavour to continue the work alone or, alternatively, relinquish it.

I am very glad it was not decided to relinquish it, although a heavy burden fell on my shoulders, and one which I felt the greatest possible diffidence and hesitation in undertaking. Since then the study of only one group of plants—the Gymnosperms—has been the serious business of the past three years; for not only have I had to study, but in the majority of cases to find the specimens as well. A comparison of the *Coniferæ* known to occur in our Tertiaries before the publication of my Monograph and since will indicate the extent of progress that I trust will be made if I am able to continue the work.

British Eocene Coniferæ described by various Authors.

	Status in Palæontogr. Soc. Monograph.
Cupressinites globosus, Bow.	Not believed to be Coniferous.
" *elongatus* "	
" *recurvatus* "	
" *subfusiformis*, Bow.	
" *curtus*, Bow.	United as *Callitris curta*.
" *Comptoni*, Bow.	
" *crassus* "	
" *thujoides* "	
" *subangulatus*, Bow.	
" *corrugatus*, Bow.	Not believed to be Coniferous.
" *sulcatus* "	
" *semiplotus* "	
" *tesselatus* "	
Cupressites taxiformis, Ung.	*Cupressus taxiformis*.
Sequoia Couttsiæ, Heer.	*Athrotaxis Couttsiæ*.
Sequoia Hardtii, "	*Sequoia Tournalii*.
Taxites Campbelli, Forbes.	*Taxus Campbelli*.
Cupressites elegans, De la Harpe.	*Podocarpus elegans*.
Pinites macrocephalus, Lindl. & Hutton.	*Pinus macrocephala*.
Pinites ovata, id.	*P. ovata*.
P. Bowerbankii, Bow.	*P. Bowerbankii*.
P. Dixoni, Bow.	*P. Dixoni*.
Pinus Plutonis, Baily.	*P. Plutonis*.
Cupressites MacHenrii, Baily.	*Cupressus Pritchardi*.
Sequoia Du Noyeri, Baily.	*Cryptomeria Sternbergii*.

List of British Eocene Coniferæ appearing in the Palæontographical Society's Monograph.

Callitris curta, Bow.	**Athrotaxis subulata*, New.
**Callitris Ettingshauseni*, New.	**Sequoia Tournalii*, Brong.
**Libocedrus adpressa*, New.	*Sequoia Shrubsolei*, New.
Cupressus taxiformis, Ung.	*Ginkgo(?)eocænica*, Ett. & Gard.
**Taxodium Europæum*, Brong.	*Ginkgo adiantoides*, Ung.
**Taxodium eocænum*, New.	*Podocarpus eocænica*, Unger.
Athrotaxis Couttsiæ, Heer.	*Podocarpus elegans*, De la Harpe.

Podocarpus argillæ-Londinensis, NEW.
Podocarpus Campbelli, NEW.
Podocarpus (?) *incerta*, „
Araucaria Gœpperti, Sternb.
Pinus macrocephala, Lindl. & Hutton.
Pinus ovata, id.
Pinus Prestwichii, NEW.
Pinus Dixoni, Bow.
Pinus Bowerbankii, Bow.
Pinus Plutonis, Baily.
**Pinus Bailyi*, NEW.
**Tsuga Heerii*, „
Cupressus Pritchardii, Gœpp.
Cryptomeria Sternbergii, „
**Taxus Swanstoni*, NEW.
Taxus Campbelli, Forbes.
Doliostrobus Sternbergii, Marion.

In this list there are twenty-eight species, fourteen of which are entirely new to science, those marked * being only known through my own collecting. Four other most important *Coniferæ* were previously unrecognised in Britain, these being *Cryptomeria Sternbergii*, *Araucaria Gœpperti*, *Doliostrobus Sternbergii*, and *Taxodium Europæum*. Many of the remainder have been defined with greater precision, especially the Irish species of *Pinus* and the English and Irish species of *Cupressus*, of both of which fruits are for the first time discovered. The true nature of other well-known *Coniferæ* is also recognised, such as that of the supposed *Sequoia Couttsiæ*, ascertained to be an *Athrotaxis*, and the Alum Bay *Cupressites*, found to be a *Podocarpus*. Finally, a number of useless species are suppressed.

Ettingshausen, in the list of Sheppey fossils already referred to, admits the following:—

Callitris curta, Bow.
C. Comptoni, „
Solenostrobus subangulatus, Bow.
S. corrugatus, Bow.
S. sulcatus, „
S. semiplotus, „
Hybothya crassa, Bow.
Cupressinites globosus, Bow.
Cupressinites elongatus, „
C. recurvatus, Bow.
C. subfusiformis, Bow.
Sequoia Bowerbankii, E. & G.
Pinus Sheppeyensis, „
Salisburia eocænica „

The only species which I am able to admit are the first and the last on the list, but I add a new *Callitris*, *Podocarpus*, *Athrotaxis*, and *Sequoia*. Similarly in the list of the Alum Bay Flora the following occur:—

Glyptostrobus Europæus, Brong.
Callitris curta, Bow.
Cupressinites globosus, Bow.
Sequoia Langsdorfii, Brong.
Sequoia Couttsiæ, Heer.
Podocarpus eocænica, Ung.

I am thoroughly acquainted with the specimens on which the above are based, and I do not think they afford satisfactory grounds for supposing these *Coniferæ* to occur at Alum Bay. The beds there are singularly poor in *Coniferæ*, and all the known specimens of true Conifers from them belong to a single polymorphic species, which the attached fruit shows to be *Podocarpus elegans*.

I trust that the results attending the expenditure of the grant we have been favoured with may be considered satisfactory, and these I now proceed to detail.

Bracklesham Flora.—Two visits have been made to Selsey. The beds, it is well known, are marine, but a few terrestrial fruits are from time to time procured from them. I have been particularly anxious before

completing my work this autumn on *Coniferæ* for the Palæontographical Society to procure fresh specimens of the Pine Cones for which the Bracklesham beds are celebrated. Only the higher beds of the series near to Selsey were well exposed on both visits, whilst the cones are found lower down in the series towards the middle of the bay. A local collector has, however, promised to procure specimens when next the proper beds are uncovered.

I was able to make a large collection of fossil shells while looking for plants, which, being from the highest beds, are less known, and are interesting as illustrating the passage from the Bracklesham to the Barton Fauna, which is more gradual, I think, than is supposed. The surface of one of these beds is dotted over with fossil *Posidonias*, a marine monocotyledonous plant identical with the species now inhabiting the Mediterranean. It had not been previously recorded as a British fossil, though another species is abundant in the contemporary beds of the *Calcaire grossier* of the Paris basin.

In our species the rhizomes radiate from a centre, whilst in the French and other European fossil species they are long and branching. They are found among beautiful *Tellina* shells, preserving, to a large extent, their banded colours. The only other fossil plant to record here is a *Nipadites*, which, unlike those of the Bournemouth beds, is large, flattened, and oval.

Reading Beds.—A considerable portion of the grant has been expended in working these beds with, I am pleased to report, the happiest results. The flora is found in the Katesgrove pit, on the banks of the Kennet, immediately beneath the mottled clay. The matrix is a fine porcelainous fuller's earth interstratified with sand, and the beds seem very local. The limit of the pit being reached it is not probable that any part of the beds will be exposed for long.

I have illustrated a beautiful specimen, one of several, of *Anœmia subcretacea*, Sap., from these beds. This Fern is highly characteristic of the lower Eocenes in France, but had only previously been found in the middle Bagshot beds of Bournemouth in this country. I have also illustrated another Fern (?) from these beds, of which I have only as yet found a small fragment. The figures are therefore taken from specimens found many years ago by Professor Prestwich. Other valuable additions to the Reading Flora are some splendid specimens of a Conifer, which I can see no ground for distinguishing from *Taxodium heterophyllum* of China. As these finds will be included in the Palæontographical volume for the present year, I need only say regarding them that *Taxodium* has been hitherto regarded as an almost exclusively Miocene plant. Another interesting specimen from Reading is a pine leaf of two needles, about the size and substance of those of *P. maritima*, the first pine foliage, I believe, ever found in the English Eocene. One leaf bed is almost wholly made up of leaves of *Platanus*, and a bed above is fairly sprinkled with fruits of the same. Fruits are very abundant, and include four kinds of leguminous pods, and there are many flowers. The variety among the leaves is relatively smaller, but all are well marked, and I expect to identify them easily by help of the fruits and flowers. As a result of this work the Reading Flora no longer appears so completely distinct from that of Bournemouth.

Woolwich Beds.—I regard these as thoroughly distinct in age from those of Reading. I have not found, in the course of two visits paid

for the purpose, any bed worth collecting from, though I think such must exist at Lewisham. I figure the crozier and venation of a very characteristic *Lygodium* from a bed of almost fœtid clay crowded with remains of rush, with which this Fern seems mingled in some profusion. I also figure a better specimen picked up at Croydon, and part of a new *Pteris* from the same. Professor Prestwich has the same *Lygodium* from Counter Hill, and also, I think, from another locality near Woolwich; so that it appears to be characteristic of the Woolwich beds.

Studland Beds.—With Mr. Keeping's help and other assistance we were able to reach a leaf bed in the Lower Bagshot at Studland, and to obtain a great number of specimens, nearly all of which are quite new to me. They are mostly dicotyledonous leaves and fruits, which will require time to determine. There are no Coniferæ among them, and I am only able to add one Fern—a *Lygodium*, very near to that of Bournemouth—to the *Chrysodium Lanzæanum* procured abundantly by me ten years ago in a different bed at the same locality.

Hordwell Beds.—Nothing much has been added to the collection made by myself and Mr. Keeping last year, when the perfectly preserved specimens of *Athrotaxis Couttsiæ* were found, our visit this year having been at too dry a season. I have, however, to add *Salvinia* to the flora, not previously found fossil in England, and exclusively confined to the Miocene in Austria and Switzerland.

Barton Beds.—Dry weather made our search for plants unsuccessful here, except for the discovery of a new species of *Pine* from Highcliff, quite unlike those hitherto found at Bracklesham. As the Stour and Avon no longer pass along the base of Highcliff, and the sea has receded there, the beds are rapidly assuming an angle of repose, and becoming deeply buried under *débris*, so that some of them are no longer visible except by making excavations. Being accompanied by Mr. Keeping, who knows the ground thoroughly, we delayed a few days to take complete sections and measurements of all the beds, which we hope to publish jointly with complete lists of the fossils peculiar to each. Though the Barton series is one of the most interesting of our Eocene formations, the detailed bedding has not been worked out like that of the Bracklesham series below and the Headon series above, and the greatest misconceptions seem to prevail as to the number of species of fossils that it contains.

Bournemouth Beds.—Fine series of leaves were obtained this year by Mr. Keeping and myself, the most noteworthy of which are some specimens of *Godoya*, which exceed any I had previously seen. I have illustrated a new and very distinct species of *Adiantum*, a fragment of what may be *Gymnogramma*, and a tufted group of *Polypodium* leaves, which seem to be different from either of the species previously recorded.

The London Clay.—Mr. Shrubsole has kindly sent me some of the best of the fruits that have been found. I have spent much time in endeavours to electrotype these, but I cannot say that, so far, the results have been quite satisfactory. It seems likely, however, that the solution of how to preserve them in an accessible manner will be found in this direction. The experiments I have made would take long to recount, and, though I have found it easy to preserve them out of liquid in a uniformly dry atmosphere, no preparation yet discovered will save them if exposed for a few months to damp air. I have not made any complete studies of them yet, but they promise to afford results of the highest value.

Among a few recognised is the very unmistakable seed of *Verschaffeltia*, a genus of Palms from Seychelles, quite new to fossil floras.

Gurnet Bay Beds.—By the kindness of Mr. A'Court Smith, who has been at great pains to despatch to me from time to time selections from his collection for examination, I have been able to study this flora at leisure during the spring. As a result, I ascertain that another Fern rivals *Anœmia subcretacea* in range, *Chrysodium Lanzœanum*, which extends from the Lower Bagshot upwards into the Bembridge beds. The plants are as a rule dreadfully macerated and chopped up. Among them are small fragments of a *Gleichenia*, which, though not very beautiful, is a very important Fern, coming from the horizon. By far the most important discovery, however, is that of *Doliostrobus*, the first really extinct Conifer that I have met with in British Eocenes. It belonged to the tribe of *Araucarieæ*, and its identification has been thoroughly confirmed by correspondence and the interchange of specimens with Dr. Marion, the well-known botanist of Marseilles. Its description will appear in the forthcoming volume of the Palæontographical Society. A visit to Gurnet Bay will be necessary in order to complete my investigations into this flora.

It is certain that during the Eocene period, as the temperature increased from the base upward to the Middle Bagshot, when the maximum of heat seems to have prevailed, there was a tendency for the plant world to move northward. It is equally certain that in the later half of the Eocene as the temperature began to decrease the movement was in the opposite direction, and we find in the European Miocenes of Switzerland and Italy a number of plants that at an earlier period were growing in the far north. In the Bembridge beds we should expect to find many plants of the Lower Eocenes reappearing that are absent in the Middle Eocenes. Two of the Reading plants reappear in the very limited flora of Hordwell, and two of the Antrim plants in that of Gurnet Bay and Hempstead. Trifling such facts appear, but they have their significance. No such forms occur among the thousands or tens of thousands of plant remains brought from Bournemouth; and we may feel quite certain that they were not comprised in our flora of that date. The moment the Hordwell Beds are searched, and among the first plants obtained from them, are two Reading species. There are of course in a flora many plants, in addition to those thoroughly at home, which are near their limits of heat and limits of cold. Those that were capable of supporting much more heat might have maintained their ground throughout the whole Eocene period, whilst of the rest that migrated some would come back with each successive decrease of temperature, while others might never again find conditions suited to them. Mere superficial observations are of no use in this study, and immense collections and minute comparisons must still be made if our knowledge of Eocene plants is ever to be commensurate with the importance of the subject.

Explanation of Plates.

Plate I.

Anœmia subcretacea, Saporta.—Reading Beds, Reading.—This fern is essentially characteristic of the older Eocenes, and even pre-Eocene, rocks. A Fern hardly distinguishable from it appears in the Cretaceous rocks of Aix-la-Chapelle, and other localities in Europe and Greenland. It is found in the old Eocene of Sézanne, in the Paris basin, and in the west of France, and in

Lower Eocene Ferns.

Middle and Upper Eocene Ferns.

Spottiswoode & Co. Lith. London.

[Il]lustrating the Report of the Committee on the Fossil Plants of the Tertiary and Secondary Beds of the United Kingdom.

the lowest stage of the Lignitic of America. It is not uncommon in the Bournemouth beds, both at Bournemouth and at Branksea Island, but had never previously been found fossil in any of our Lower Eocenes, so that its discovery at Reading is important. It seems not to have extended beyond the Middle Eocenes, to have always been a relatively northern form, and to be now extinct.

PLATE II.

Fig. 1. Fragment of a feather-veined Fern from the Woolwich beds of Croydon. The form is new to our Eocenes, but too fragmentary to be determined. It may be an *Acrostichum* or *Pteris*.

Fig. 2. *Lygodium Prestwichii*, Et. and Gard. sp.—From the Woolwich beds, Croydon; figs. 3 and 4 from Woolwich. A small fragment of this was originally figured by Professor Prestwich in the 'Quart. Journ. Geol. Soc.,' vol. x. p. 156, pl. III. fig. 6. We thought it might be a *Pteris*, not having examined any original specimen, but did not make any definite determination, beyond the opinion that 'there is no particular reason to suppose it to be a *Pteris*; but in the absence of contradictory generic characters we have thought it convenient to consider it as belonging to that genus.' ('Brit. Eocene Flora,' vol. i. p. 53.) I have since examined Professor Prestwich's specimens, and obtained others myself from Croydon and from Woolwich. The pinna was simple or cleft into two or more lobes. The veins are free, and diverge at a sharp angle from the midrib, are crowded, and fork once or twice. The margin is irregularly toothed, the teeth being the bases of fertile segments of the frond, which look as if easily removable by rubbing or maceration. It is perfectly indistinguishable from *Lygodium japonicum*, Sw., an inhabitant of Japan and Hong Kong, Ceylon, Java, the Philippines, &c., of the section Eulygodium. It is quite distinct from the Bournemouth *L. Kaulfussii*, and its determination is a great acquisition to our flora. It is undoubtedly the *Pteris pseudopennæformis*, Lesq., from the first stage of the American Lignitic, and may be identifiable with other European species.

Fig. 3 represents some venation enlarged.

Figs. 5 to 12 represent specimens from Reading in Professor Prestwich's collection. The hard striated stipes, and the cutting and venation of the leaf, are very fern-like, the latter suggesting segments of *Asplenium Thunbergii*; but the straggling growth is rare among Ferns, though possessed by some species of *Acrostichum*, *Anæmia*, and others. I have met with nothing living resembling it, and if a Fern, it is now completely extinct.

Figs. 5*a*, 6*a*, 8*a*, 9, 10 are enlargements, and the rest natural size.

PLATE III.

Figs. 1 and 2. Small fragments of a *Gleichenia* from the insect beds of Gurnet Bay. The venation is very obscure, the mid-rib strong, the texture coriaceous. The specimens are interesting as marking the first appearance in the English Eocenes of a type of Fern that abounded in the Cretaceous beds of Europe and the Eocenes of Antrim and Greenland.

Figs. 1*a* and 2*a* are enlarged.

Figs. 3 and 4 seem fragments of dicotyledonous leaves, shrivelled, and perhaps eaten by insects, but superficially resembling the *Gleichenia*.

Fig. 5. Specimen of *Chrysodium Lanzæanum* from Gurnet Bay. This Fern first appears in the Lower Bagshot of Studland, and maintains its ground through the whole of the Bournemouth series. It again appears in diminished size in the Hordwell beds and the Bembridge beds, and is identical with a still living and widely distributed tropical Fern, *C. aureum*.

Fig. 6. Fragment of Fern from Gurnet Bay. The pinnules are very minute, and are like those of *Gymnogramma flexuosa*, Desv., as well as species of *Lindsaya*, *Microlepia*, &c. It is too small for determination. All the above are lent by Mr. A'Court Smith.

Fig. 7. *Phymatodes polypodioides*, Ett. and Gard., from Bournemouth. This appears an undoubted Polypodium belonging to the section *Phymatodes*. The fronds are far longer and more linear than those of *P. polypodioides* of Bournemouth, yet it seems hardly possible to separate it as a distinct species. The bases of attachment are, most unfortunately, absent in all, but their disposition almost

proves that they were fronds tufted on a rhizome and not lateral pinnæ, as I had surmised from the isolated specimens previously known. Their resemblance to the living *P. geminatum* and other tropical American species is very striking.

Fig. 7*a* is enlarged twice, and 7*b* four times.

Fig. 8. Fragment of a Fern from Bournemouth, very like *Gymnogramma aurea*, the Golden Fern of our conservatories, but with larger pinnules. It might prove to be an *Adiantum* or *Lindsaya*, but the veins are relatively wide apart. Though in beautiful preservation the fragment is too small for determination.

Fig. 8*a* is part of the same enlarged twice.

Fig. 9. Fragment of *Lygodium* from the Lower Bagshot, Studland. Though like the Bournemouth *L. Kaulfussii* the veins are much closer, and it seems intermediate in form between that and the Woolwich species. No Lygodium of this age was previously known.

Fig. 10. *Adiantum* from Bournemouth. The rachis has somehow disappeared, leaving the pinnæ undisturbed in their relative positions. It is quite distinct from any fossil *Adiantum* previously known, and is identical with *A. flabellulatum*, Linn., of Ceylon, Japan, Hindostan, and the Malayan Peninsula and Islands. The unique impression is exceedingly fine, delicate, and colourless. The enlargement, fig. 10*a*, has, I fear, not quite included the margin, which is very slightly denticulate, and too much mid-rib is shown, for most of the veins actually diverge from the base, repeatedly forking, so that their relative distances are maintained to the margin. They are more crowded than in another Bournemouth maidenhair, *A. apalophyllum*.

These Ferns add to the large number of plants already known that migrated from our latitudes after the Eocene, and are now found established in Western Asia and Central America. Though fragmentary, most of them are new, and, being omitted in our Monograph, deserve to be recorded.

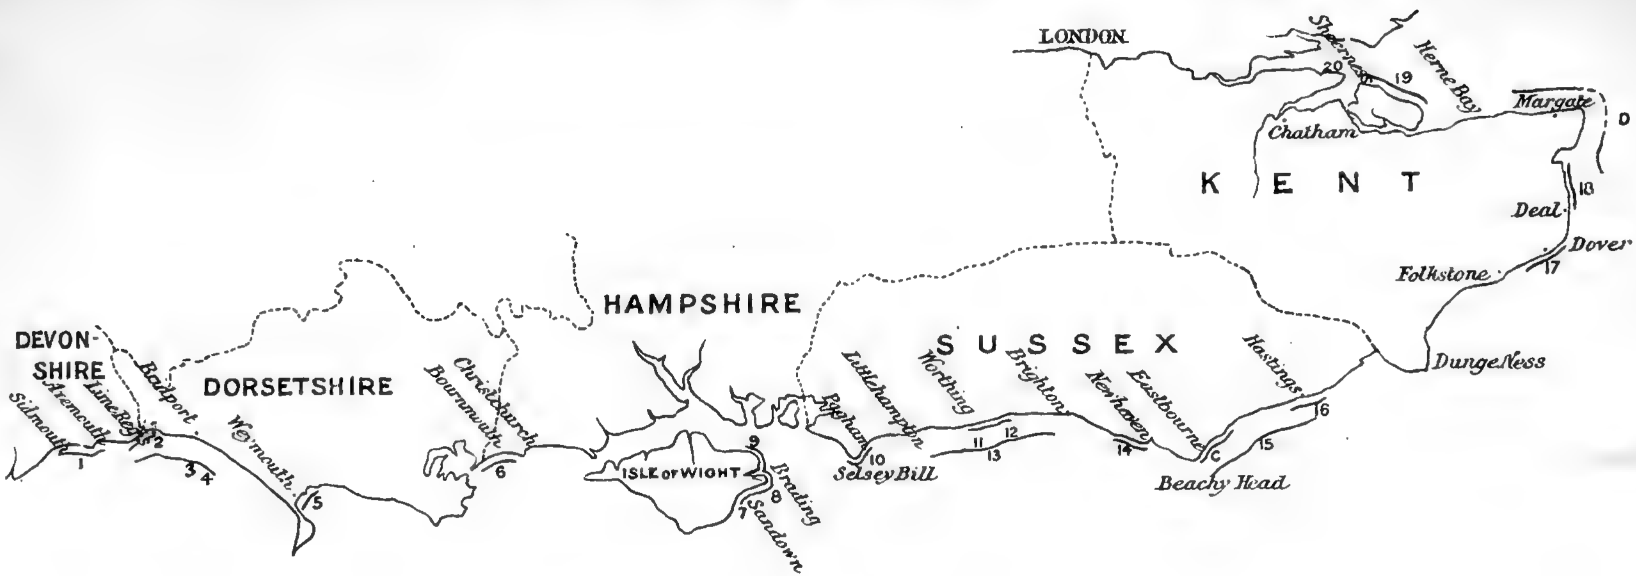
Report of the Committee, consisting of Messrs. R. B. GRANTHAM, C. E. DE RANCE, J. B. REDMAN, W. TOPLEY, W. WHITAKER, *and* J. W. WOODALL, Major-General Sir A. CLARKE, Sir J. N. DOUGLASS, Captain Sir F. O. EVANS, Admiral Sir E. OMMANNEY, Captain J. PARSONS, Professor J. PRESTWICH, Captain W. J. L. WHARTON, Messrs. E. EASTON, J. S. VALENTINE *and* L. F. VERNON HARCOURT, *appointed for the purpose of inquiring into the Rate of Erosion of the Sea-coasts of England and Wales, and the Influence of the Artificial Abstraction of Shingle or other Material in that Action* (C. E. DE RANCE *and* W. TOPLEY, *Secretaries*; *the Report edited by* W. TOPLEY.)

[PLATE IV.]

THE importance of the subject referred to this Committee for investigation is universally admitted, and the urgent need for inquiry is apparent to all who have any acquaintance with the changes which are in progress around our coasts. The subject is a large one, and can only be successfully attacked by many observers, working with a common purpose and upon some uniform plan.

In order fully to appreciate the influence, direct or indirect, of human agency in modifying the coast-line, it is necessary to be well acquainted with the natural conditions which prevail in the places referred to. The main features as regards most of the east and south-east coasts of England

SKETCH-MAP *shewing the Districts referred to in the Report.*



Spottiswoode & Co. Lith. London.

Illustrating the Report of the Committee on the Erosion of the Sea coasts of England & Wales.

are well known; but even here there are probably local peculiarities not recorded in published works. Of the west coasts much less is known. It has therefore been thought desirable to ask for information upon many elementary points which, at first sight, do not appear necessary for the inquiry with which this Committee is intrusted.

A shingle-beach is the natural protection of a coast; the erosion of a sea-cliff which has a bank of shingle in front of it is a very slow process. But if the shingle be removed the erosion goes on rapidly. This removal may take place in various ways. Changes in the natural distribution of the shingle may take place, the reasons for which are not always at present understood; upon this point we hope to obtain much information. More often, however, the removal is directly due to artificial causes.

As a rule, the shingle travels along the shore in definite directions. If by any means the shingle is arrested at any one spot, the coast-line beyond that is left more or less bare of shingle. In the majority of cases such arresting of shingle is caused by building out 'groynes,' or by the construction of piers and harbour-mouths, which act as large groynes. Ordinary groynes are built for the purpose of stopping the travelling of the shingle at certain places, with the object of preventing the loss of land by coast-erosion at those places. They are often built with a reckless disregard of the consequences which must necessarily follow to the coast thus robbed of its natural supply of shingle. Sometimes, however, the groynes fail in the purpose for which they are intended—by collecting an insufficient amount of shingle, by collecting it in the wrong places, or from other causes. These, again, are points upon which much valuable information may be obtained.

Sometimes the decrease of shingle is due to a quantity being taken away from the beach for ballast, building, road-making, or other purposes.

Solid rocks, or numerous large boulders, occurring between tide-marks, are also important protectors of the coast-line. In some cases these have been removed, and the waves have thus obtained a greater power over the land.[1]

The Committee has during the past year received several Returns relating to the south and east coasts of England. Those relating to the coast south of the Thames are here printed, with the exception of one by Mr. K. McAlpin on Pembrokeshire.[2] As the amount of change on the rocky coast here described is small, and as the Return is accompanied by several photographs—without which illustrations its value would be much decreased—the publication of this is deferred.

The other Returns in hand are:—J. Bateman, Estuary of the Colne[2]; P. S. Bruff, R. Deben to near R. Colne[4]; Maj. A. G. Clayton, Great Yarmouth[2]; W. Teasdell, Aldeburgh to Cromer[3]; A. C. Savin, Weybourne to Happisburgh[4]; Clement Reid, Weybourne and Palling[4]; C. Fox-Strangways, Scarborough[4]; Lieut.-Colonel Melville, Northumberland coast.[2]

The thanks of the Committee are especially due to Major-General Sir A. Clarke, who has instructed the Officers of the Royal Engineers

[1] The foregoing paragraphs, giving a general statement of the objects of this Committee, are reprinted from the preliminary Report of last year.

[2] Supplied through Sir A. Clarke. [3] Supplied through Mr. J. B. Redman.

[4] Supplied through Mr. W. Topley.

stationed around the coast to supply the Committee with such information as they may possess or may be able to obtain. Further returns are expected from the same Department and from other official sources; the Committee therefore think it best to defer any general Report until more complete information is obtained.

The Report by Mr. J. B. Redman on the South-Eastern Coast so fully sets forth the work of the Committee, and the importance of the inquiry referred to it, that this is now printed.

The Report by Mr. G. Dowker on the Coast of East Kent gives an account of the changes of the coast in this district, changes which are of especial historical importance and interest.

Mr. Whitaker has drawn up a List of Works on the Coast-Changes and Shore-Deposits of England and Wales, which will be of great service to the Committee and to those who may assist in the inquiry. In order to make this as complete as possible, it has been brought down to the date of publication.

The various Reports—General and Local—are printed on the authority of the respective authors. The Full Report of the Committee is deferred.

The Committee would again ask for the assistance of any who, by long residence or by other means, have special knowledge of changes on any part of the English and Welsh coasts. Printed forms of questions can be obtained from the Secretaries or from any member of the Committee.

Copy of Questions.

N.B.—Answers to these questions will in most cases be rendered more precise and valuable by sketches illustrating the points referred to.

1. What part of the English or Welsh Coast do you know well?

2. What is the nature of that coast?

- **a.** If cliffy, of what are the cliffs composed?
- **b.** What are the heights of the cliff above H.W.M.? Greatest; average; least.

3. What is the direction of the coast-line?

4. What is the prevailing wind?

5. What wind is the most important—

- **a.** In raising high waves?
- **b.** In piling up shingle?
- **c.** In the travelling of shingle?

6. What is the set of the tidal currents?

7. What is the range of tide?

- (1) Vertical in feet. (2) Width in yards between high and low water.
- (**a**) At Spring tide; (**b**) at Neap tide?

8. Does the area covered by the tide consist of bare rock, shingle, sand, or mud?

9. If of shingle, state—

- **a.** Its mean and greatest breadth.
- **b.** Its distribution with respect to tide-mark.
- **c.** The direction in which it travels.
- **d.** The greatest size of the pebbles.
- **e.** Whether the shingle forms one continuous slope, or whether there is a 'spring full' and 'neap full.' If the latter, state their heights above the respective tide-marks.

10. Is the shingle accumulating or diminishing, and at what rate?

11. If diminishing, is this due partly or entirely to artificial abstraction? (*See* No. **13**).

12. If groynes are employed to arrest the travel of the shingle, state—

- **a.** Their direction with respect to the shore-line at that point.

b. Their length.
c. Their distance apart.
d. Their height—
(1) When built.
(2) To leeward above the shingle.
(3) To windward above the shingle.
e. The material of which they are built.
f. The influence which they exert.

13. If shingle, sand, or rock is being artificially removed, state—
a. From what part of the foreshore (with respect to the tidal range) the material is mainly taken.
b For what purpose.
c. By whom—Private individuals. Local authorities. Public companies.
d. Whether half-tide reefs had, before such removal, acted as natural breakwaters.

14. Is the coast being worn back by the sea? If so, state—
a. At what special points or districts.
b. The nature and height of the cliffs at those places.
c. At what rate the erosion now takes place.
d. What data there may be for determining the rate from early maps or other documents.
e. Is such loss confined to areas bare of shingle?

15. Is the bareness of shingle at any of these places due to artificial causes?
a. By abstraction of shingle.
b. By the erection of groynes, and the arresting of shingle elsewhere.

16. Apart from the increase of land by increase of shingle, is any land being gained from the sea? If so, state—
a. From what cause, as embanking salt-marsh or tidal foreshore.
b. The area so regained, and from what date.

17. Are there 'dunes' of blown sand in your district? If so, state—
a. The name by which they are locally known.
b. Their mean and greatest height.
c. Their relation to river mouths and to areas of shingle.
d. If they are now increasing.
e. If they blow over the land; or are prevented from so doing by 'bent grass' or other vegetation, or by water channels.

18. Mention any reports, papers, maps, or newspaper articles that have appeared upon this question bearing upon your district (copies will be thankfully received by the Secretaries).

19. Remarks bearing on the subject that may not seem covered by the foregoing questions.

General Reports.

A.—The South-Eastern Coast of England.

By J. B. Redman, F.G.S., M.Inst.C.E.

July 21, 1884.

That the erosion of our south-eastern coasts by the action of wind-waves has been assisted and increased by artificial agency, by removal of material and by the treatment of works of defence in a selfish spirit, unaccompanied by concerted action, resulting in injury to adjoining frontages for the benefit of those operated on, can be copiously illustrated by the records of our public departments, such as the Admiralty, Woods and Forests or Works, the Board of Trade, the War Office, and the Trinity Corporation, as well as by those of nearly every harbour board, river conservancy, or local drainage and sewage authority. And this fact is pourtrayed in a special literature of its own; the Blue Books of the House of Commons, for the various tidal harbours' reports, inaugurated by the persistent agitation of the late Joseph Hume, M.P., as well as those on harbours of refuge, lighthouses, and shipping, give incidentally numerous isolated cases showing how much this really imperial question has been overlooked or confused by a division of authority; and the struggles with lords of the manor, illustrated by a number of well-known cases, add additional exemplification.

The legal aspect of this question has been recently ably treated by a republication of Hall's 'Essay on the Rights of the Crown in the Sea-shore,' by Richard

Loveland Loveland, of the Inner Temple, in 1875; and this work shows well the imperial character of the inquiry deputed to the British Association Committee on the Erosion of the Sea Coasts of England and Wales.

We are told in this essay, on p. 2, that 'this dominion or ownership over the British seas, vested by our law in the king, is not confined to the mere usufruct of the water and the maritime jurisdiction, but it includes the very *fundum* or soil at the bottom of the sea.'

The effect resultant on the frequent piercing of our sea littoral by estuaries, creeks, and rivers is graphically described on p. 3, indicative of the extent of territory involved. 'This dominion not only extends over the open seas, but also over all *creeks, arms of the sea, havens, ports, and tide rivers*, as far as the reach of the tide, around the coasts of the kingdom. All waters, in short, which communicate with the sea, and are within the *flux* and *reflux* of its tides, are part and parcel of the sea itself, and subject, in all respects, to the like ownership.'

'Grants of the sea-shore by the king' are treated on at p. 14, and 'As to the claims of lords of manors to the sea-shore' at p. 17.

'As to digging for sand, &c.,' we have, at p. 92, the following apposite opinion:—'With regard to the "constant and usual fetching of sea-sand, seaweed, and gravel, between the high-water and low-water mark, and licensing others so to do; and embanking against the sea, and enjoyment of what is so *inned*"—these, it must be admitted, are all acts likely to be done by the owners of the soil, and they afford colour that he who does such acts is the owner; but these acts may be usurpations or intrusions on the king's ownership, and *primâ facie* are so.'

The sea-coast margin is at p. 108 divided into three categories, the treatise saying that, 'as to alluvion and derelict land, land gained from the sea is of three kinds:

'1st. *Per alluvionem*, alluvion, or land washed up by the sea.

'2nd. *Per relictionem*, derelict land, or land left dry by the shrinkage or retirement of the sea.'

And at p. 109 we read: 'The law on this part of the subject is laid down by Blackstone in these words:—"As to lands gained from the sea, either by *alluvion, i.e.*, by washing up of sand or earth, so as in time to make *terra firma*; or by *dereliction*, as when the sea shrinks back below the usual water-mark, in these cases the law is held to be that, if this gain be by little and little, by small and *imperceptible* degrees, it shall go to the owner of the land adjoining, for 'de minimis non curat lex;' but if the alluvion or dereliction be sudden and considerable, the land shall go the king, as lord of the seas."'

The land gained from the sea in the third category would be that from which the waters had been excluded by artificial works of embanking and drainage, generally applicable to salt marshes of silty deposit gradually risen to the height of neap-tide flow, but only covered by spring tides.

It is curious to find Blackstone and his commentators talking of these salt-slob lands, which, by their gradual accretion, have risen above the influence of all but great tides, as *dereliction* caused by the shrinkage of the sea below its usual level, whereas the converse is the case, the surface gradually rising and shutting out the tide by its own proper operation. The fact that O. D. is mean level of the sea is sufficient illustration of Blackstone's physical inaccuracy in this special instance.

As regards the wholesale removal of shingle and boulders from marine spits and moles, it is only necessary to refer to such cases as the quarrying of cement stones from the foreshores on either side of Harwich, from the Beacon cliff to the southward, and from the Felixstow cliffs to the northward, only stopped by the persistent efforts made by Captain Hewett's successor in the North Sea Survey, the late Admiral Washington, and others. For illustration of this pernicious practice and the deplorable results frequently entailed this case suffices. Again, on the northern side, the indiscriminate removal of shingle from the northern breakwater of Harwich harbour (Landguard Point) for ballastage by the lord of the manor has been the fruitful source of litigation. Similar results from similar practices at Spurn Point, at the mouth of the Humber, have been entailed. In effect, this natural shingle mole, defending the entrance to the most important harbour on our eastern coast, was nearly breached in consequence.

Next to the removal for ballastage, the most fertile cause is removal of material for road-making and for building purposes, and when in the neighbourhood of a large town this becomes, from the enormous quantity removed in the aggregate, sufficient to tell eventually on the oscillating natural foreshore protection. Take the case of Hastings: for the last half-century there has been a constant draw on the material

for such purposes. The quantity used must be enormous, and in effect the new portion of the town may almost, without figure of speech, be described as in a large measure built out of the sea. About 1836 Hastings was separated from St. Leonards by a small marshy bottom, with a rill of water running through it, called the 'Priory Marsh,' and during that year the sea was excluded by the erection of a vertical stone wall joining the esplanade terraces, and the two towns became what it is now, one big town. Since that wall was erected the shingle in front of it has, from various causes, become much attenuated, the groynes destroyed, and the sea has, it is said, in places got under the sea walls. So great has been the loss in the bay to the eastward, where is situate the old portion of the town, the fishermen's quarter, that a general exodus of that industry to Rye, or elsewhere, has been threatened.

A second groyne is being constructed from the base of the East Cliff (where a similar work formerly existed) at a very great cost, in order to promote accumulation of shingle along the Hastings frontage, and to bring about again the old state of things.

The argument made use of by many owners of property here, as elsewhere, to the effect that removal of shingle for building purposes must be inappreciable (as, however great the abstraction for such purposes, millions of tons renew the shore after a change of wind) is made in evident forgetfulness or ignorance of the fact that these abstractions from and renewals to the natural 'fulls' of beach, alternately reduce and increase what is a circulating medium of defence, moving in opposite directions up and down channel, with a preponderating movement up channel, due to prevalence of south-west winds, and that such a constant drain on a natural defence, however recuperative, must tell in the long run.

The removal of boulders from the foreshore seaward of the summit shingle neap and spring 'fulls,' either for road-making or for manufacturing purposes, not only loosens the foreshore, and renders it, thus disintegrated, less able to resist the stroke of the wave, but in many cases, such as the 'Chenies' rock off Sheerness, and the 'Septaria' blocks off Harwich, the material formed natural groynes and breakwaters, and their removal, in reference to shore conservancy, was most suicidal.

Another fertile source of accelerated erosion of a special locality is the erection of a close pier for a harbour entrance, and of large and lofty groynes for accumulating shingle, looking only to the protection of an isolated frontage, and without reference to the attendant abstraction of material to the leeward of such works, from the absolute stoppage of the material on its way to the less favoured locality. The case is parallel to the last, as the oscillating medium is laid under heavier contribution for a favoured locality, and is gradually starved for the neglected neighbour to leeward.

Folkestone may be cited as a principal delinquent of this class, due to the elongation of the close pier to the windward or westward of its harbour, which half a century back was a trap for shingle; and a fisherman's first task in the early morning, prior to that, was to excavate a channel through the newly-arrived shingle to get his boat through and out to sea. The resultant accumulation of shingle to windward forms the tongue of land on which stands the 'Pavilion,' &c.

Now, in 'East Wear' Bay there is an almost entire absence of shingle, and the resultant falls of the chalk undercliff take place at so alarming a rate that the very existence of the South-Eastern Railway is jeopardised. That this action is not due to the Admiralty pier at Dover is shown by the entire absence of shingle to windward of that work, but in its place a remarkable extension of the silty foreshore has taken place, gradually diminishing towards Folkestone. Eastward of Dover we have similar results from the same cause; from the Castle jetty to St. Margaret's the base of the lofty chalk cliff is now washed and abraded by the waves, and the lower *débris* and shingle, forming an undercliff carriage-way into Dover some thirty years back, has now entirely disappeared.

We may be asked to suggest a remedy, but this, perhaps, is beyond the province of this Memorandum; but as regards the old stereotyped plan of building a solid pier out from the shore, for communication therewith from vessels, or for protection of the outfall of a tidal river, it has been suggested that there are numerous cases where a moving beach has to be crossed, that it would be better to commence the solid work altogether seaward of the shingle 'fulls,' and connect it with open piling to the shore, and so as to leave the littoral movement of beach uninterfered with.

As respects groynes, there is hardly a watering-place on our southern coast where they have not become a burning *vexata quæstio* of the day, and, at most of them, illustrate the suggestion made more than thirty years back, that groynes cut

up a shore into a multitude of bays, with a repletion of material on one side and deep water on the other, and would have had a better substitute in a sea-wall that allowed the shingle to pass freely backwards and forwards along its face. Such was the experience with the frontage of Romney Marsh, defended by Dymchurch sea-wall, $3\frac{1}{4}$ miles in length, where the old system of groynes, which cut up the frontage into an interminable number of bays, was abandoned about forty years back in favour of the present stone slope ('Proc. Inst. C.E.' vol. vi., plan and sections).

The system of groynes at Brighton, for some isolated points, appeared to have answered well when the supply arriving at that town of shingle from the westward was uninterfered with, but a change occurs when the system was continued to Hove, or West Brighton, in thickening quantities. The material arriving was a constantly diminishing one, from the fact that the Shoreham Gas Works, erected under an Act of Parliament on the 'live' beach between the harbour and the sea, were found to stand upon a somewhat unstable base, with a fickle sea defence, unless supplemented by artificial works. Groynes on an extended scale were erected, which treated West Brighton in the same ungenerous spirit entertained in former days for Rottingdean, for the sake of and advantage of Kemp Town. The encroachment of the sea to the leeward side of the groynes, on the esplanade lawns, has necessitated the erection of an esplanade wall.

B.—The South-Eastern Coast of England.

By Colonel E. C. Sim, R.E. (Retired).

To the Commander Royal Engineers, Brighton.

55 Lower Belgrave Street, London. Dec. 4, 1884.

Sir,—With reference to War Office Memo. Oct. 23, 1884, and the Minute of the Commander Royal Engineers, S.E. District, thereon, dated Oct. 25, 1884, and enclosure returned herewith, I have the honour to state that as I have been employed as C.R.E. at three stations in the Chatham and S.E. Districts during the last five years, which stations have all more or less been connected with foreshore questions, in which I have taken great interest, as affecting War Department property and rights, I trust I may be allowed (although on the Retired List) to make a few remarks about 'The rate of erosion of the sea coasts of England and Wales, and the influence of the artificial abstraction of shingle and other material in that action,' as mentioned in the circular of the British Association for the Advancement of Science.

With reference to the coast-line from Sheerness to Shellness Point in the Isle of Sheppey, with which I was well acquainted from 1879 to 1882, it would appear that the high land of Warden Point, which is nearly the only cliff in Sheppey, is gradually being undermined by the action of springs and the sea; the débris being more or less conveyed by the tide towards Sheerness, and the limestone-nodules, or lumps from the débris, are collected afterwards by the fishermen and others on the beach, and sold for lime and cement. The coast-line near Leysdown station is being denuded of shingle likewise, and a stone apron erected some years ago near the coastguard station has been washed up and practically destroyed in 1880. The movement of the shingle is from east to west along the estuary of the Thames; and if it were not caught by the Garrison Point Fort, which is protected by strong wooden groynes put down when the fort was erected, my opinion is that the whole of Sheerness would be submerged. The point acting as a breakwater and large groynes 'backs up' the shingle along the whole front of the fortifications, which are also protected by groynes, and so on to Sheerness Marine Town and Cheyney Rock, W. D. property; after which, in my time, the foreshore was so exposed by the absence of groynes and want of care and attention, that it seemed likely the whole of the adjoining lands would be submerged at high tides, the sea-wall or dyke also being ineffective. I am unable to give any exact description of the formation of the cliffs in Sheppey. I believe they are of London Clay (with nodules of impure limestone or septaria), and are from 60 to 80 feet in height. The foreshore of shingle in front of Sheerness and Mile Town extends for perhaps 80 yards at low water. While on this subject, I may as well mention that the southern or right bank of the Medway at Sheerness, from the Royal Dockyard to Queenborough, had also to be protected against the inroads of the sea or river by groynes and dykes, or walls. The 'wash' near Queenborough Pier

was very great, and we constantly had to employ gangs of men in refacing the front and top of the river walls. On the north side or left bank of the Medway, at the Isle of Grain, where the large fort was built for the protection of the entrance to the river, &c., the sea or estuary made great inroads in the foreshore of clay or mud which formed the foot of the glacis of the fort. The sea-walls and groynes built at the point opposite the dockyard at Sheerness had to be constantly repaired and kept in order, or the foreshore would have gone altogether. The action of the sea or estuary in this case, as well as at Sheerness generally, was most effective when the wind was N.E. and the tides high; there was scarcely any shelter from the N.E., the water was driven up with great force over the walls, and the shingle at the groynes was disturbed; and at the great storm during the frost of January 1881, the sluices which should have let the surface-water out were frozen, and the whole of the low-lying ground was flooded and afterwards frozen, which did a great deal of damage to property, and caused much malaria afterwards.

The direction of the groynes generally was N.E. towards the prevailing wind, and the accumulation of shingle to windward was often 6 or 7 feet higher than the other side. There was scarcely any movement of shingle when the wind was westerly and from the south, as the coast-line was well protected by the adjoining banks and shoals. With regard to the abstraction of shingle from the foreshore at Sheerness, no doubt the proprietor of the foreshore at Marine Town used to sell the shingle to builders and others, but as the sea-wall at this place was considerably retired in position, I am not sure that much harm was done in my time. At Garrison Point, inside the line of fortifications, we allowed a small amount of shingle to be taken for building purposes, but only on the river-front. Beyond Cheyney Rock and towards Warden Point, a great deal of shingle was taken away by builders and others to make concrete. My own opinion is that, as a rule, none should be allowed to be taken from Sheerness, as the whole front is really artificially kept up, and the shingle is a very important factor in the matter. Where there is a great accumulation of shingle at groynes it may be allowed, in exceptional cases, to remove shingle for W.D. purposes.

With regard to the coast-line from Folkestone to Dungeness and Winchelsea, with which I was acquainted in 1882 and 1883, I would state generally that the sea is making inroads near Folkestone towards East Wear Bay, caused no doubt by the scour of the sea thrown on the foreshore by the piers of the harbour; but the three towers on the cliff above are not affected thereby. The S.-E. Railway Company are protecting the front of the town near the Pavilion Hotel and Pier, and towards Sandgate many groynes have been constructed. Sandgate Castle has, I believe, been taken over by the S.-E. Railway Company, and I imagine they will protect the foreshore there. The sea-walls at Seabrook and Hythe were much damaged by a gale in 1882, from want of the proper number of groynes; these have, I believe, since been provided by the S.-E. Railway Company.

From Hythe to Dymchurch and Dungeness, as I understand, the Lords of Romney Marsh keep up the canal sluices, sea-walls, groynes, &c., and do it very well; doubtless they prevent shingle from being taken. From Dungeness to Winchelsea the same rule applies, and except where the foreshore of the towers and forts occasionally intervenes, I imagine the whole coast-line is protected by these Commissioners of Levels. The movement of shingle towards Dungeness Point from the westward is very apparent; it is caught up there, and the foreshore is gradually increasing. At one time the sea came up to Winchelsea, Lydd, and New Romney, although they are now a considerable distance inland. I should say that the sea is encroaching a little between Dungeness and Rye, but Rye Harbour is becoming shallower. I do not imagine shingle is allowed to be taken from the foreshore here, except under very careful supervision.

From Winchelsea to Hastings I know but little; except that near Hastings, at Rock-a-Nore Cliffs, one very large stone groyne has been built, and one is in course of construction near the Practice Battery, which effectually keep up the shingle and prevent it going eastward and undermining the cliffs and damaging the Fisherman's Town. The whole front of Hastings and St. Leonards is protected by sea walls and groynes kept up by the local authorities, and I imagine shingle is only allowed to be taken in small quantities for public building purposes. From Hastings to Bopeep and to Bexhill considerable inroads have been made by the sea, and some of the old Martello-towers have gone. The lord of the manor or local authority at Bexhill is building a sea-wall there to protect the front and form an esplanade; but at the neighbouring foreshore west much of the ground has been recently washed away, and until Pevensey Bay

is reached there is no local authority interested apparently in preserving it. The Commissioners of Pevensey Levels are supposed to protect the foreshore from Bexhill towards Eastbourne; a few groynes have been made by them and by the L.B. and S.C. Railway Company, but no great efforts are made to keep up the bank of shingle. The wash or scour from Eastbourne has, I fancy, affected this part a good deal. The whole front of Eastbourne, from the Circular Redoubt to near Beachy Head, is protected by groynes and sea-walls kept up by the town. I understand that the sea has during the gale now raging made another breach in the wall at the east end of Circular Redoubt, Eastbourne. Last year a breach was made and temporarily repaired; but as the Commissioners of Pevensey Levels did nothing to repair their groynes and sea-defences, doubtless the sea has got in behind the W.D. sea wall and has flooded the adjacent land. The local authorities of Eastbourne intended to have taken over this portion, and to have extended their sea-wall along the whole front of the War Department property.

From Beachy Head to Seaford, I am not aware of the state of the coast-line; the high cliffs of chalk, &c., are, I understand, being undermined in places; but I do not think there is much shingle at their foot. From Seaford Head to Newhaven there is considerable beach kept up by groynes and sea wall. An esplanade has also been formed by the Commissioners. On the Newhaven side, under the fort, shingle is allowed to be taken by the Harbour Commissioners to make into concrete, but as the beach is protected by the pier and breakwater, no shingle can pass to the eastward, and no harm is done.

From Newhaven to Rottingdean and Brighton, I fancy the cliffs are being gradually undermined by the action of the sea. There is a shingle beach at Rottingdean which is used by bathers, but I fancy that the scour of the shingle caused by the sea defences of Brighton has denuded the foot of the cliffs between Rottingdean and Brighton of any shingle deposited there. The sea-defences of Brighton in the shape of groynes and sea-walls are of course kept up by the local authorities very carefully, as the importance and popularity of the place depend upon the sea-front. At Hove the recent works designed by Sir John Coode are approaching completion.

From Brighton to Shoreham the 'head' or 'full' of the beach of the peninsula formed by the Aldrington Basin, &c., is, I believe, well kept up. I do not think shingle is allowed to be removed thence. At Shoreham Harbour, to the west of the river Adur, the shingle is taken by the Commissioners from their property under the Redoubt and barged away to Brighton for making concrete at the new sea-defences. Apparently the shingle accumulates as fast as it is taken away. From Shoreham to Worthing, I cannot say that I know much. I believe the 'head' or 'full' of the beach is kept up, and I have never heard of any breaches made by the sea there. At Worthing the local authorities keep up the sea-walls and groynes to form an efficient esplanade and roadway. I do not think that shingle is removed. At Littlehampton the sea-front is protected by groynes and sea-wall, but the foreshore is principally of sand. The shingle lies to the westward of the river Arun, and thence sandhills and dunes form an efficient protection from the inroads of the sea.

At Bognor the local authorities are gradually improving the sea-front with groynes and sea-walls, but I fancy the sea makes many inroads into the foreshore adjacent; shingle should certainly not be removed from this place.

I have the honour to be, Sir,

Your most obedient Servant,

(Signed) E. C. Sim, Colonel.

Remarks on Groynes for Sea Defences.

1. Groynes are indispensable—1st. To check the movements of shingle. 2nd. To assist in forming a 'head' or 'full' of beach. 3rd. To cover the 'tie' or foot of sea-walls with shingle, and prevent them being undermined.
2. They should be directed towards the prevailing dangerous wind.
3. If the coast suffers from both quarters—i.e. S.E. and S.W. winds—land-ties on each side are necessary.
4. Short groynes—say 80 feet long—are better for protecting walls, in my opinion.
5. Long groynes are better for forming 'head' or 'full' of beach.
6. I consider that an 80-feet groyne will protect a part of about 100 feet. If there is much scour they should be *closer*.

7. The great object is to get the *beach* just to fall over the top and accumulate on the leeward side as well as the windward.
8. The Hastings, Eastbourne, and Brighton groynes are good ones; although some at Eastbourne are, in my opinion, too high.
9. If the piles or uprights are long enough, sheeting can always be added afterwards if necessary.

(Signed) E. C. SIM, Colonel R.E., Retired List.

December 4, 1884.

C.—The Erosion of the Sea-Coast between Langney (or Langley) Point and Beachy Head, Sussex.

By F. W. BOURDILLON, M.A., Eastbourne.

The erosion of this part of the coast has been treated of by Mr. J. B. Redman, in the 'Proc. Inst. C. E.,' vol. xi. p. 162, also by the Rev. H. E. Maddock, in a paper read before the Eastbourne Natural History Society in 1875, and published in their Proceedings. But the 'Survey of the Coast of Sussex,' made in 1587, and edited of

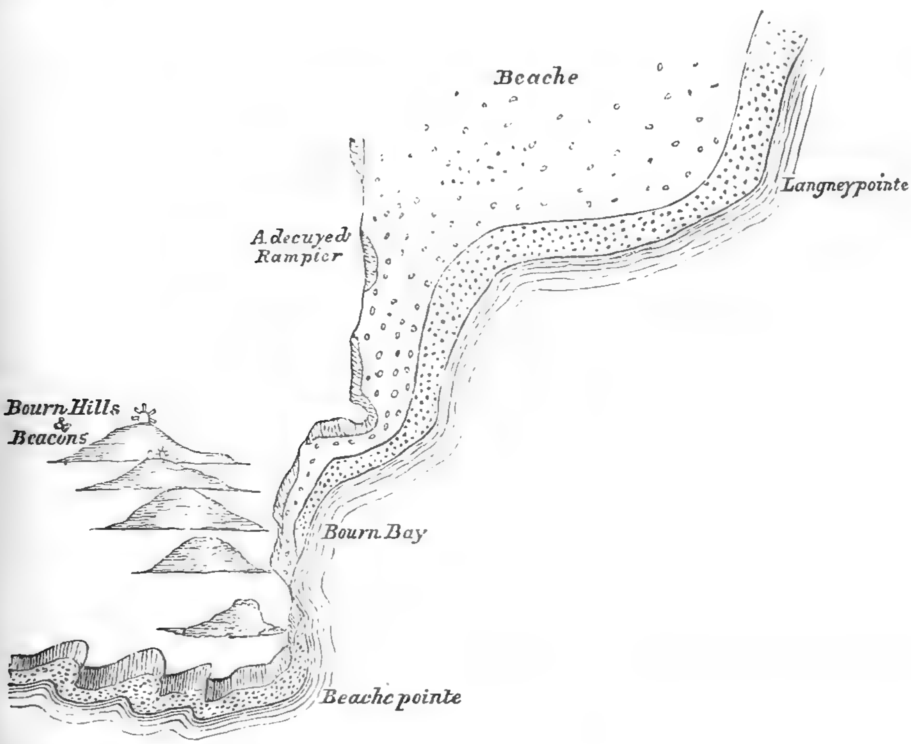


FIG. 1.—The Coast from Beachy Head to Langney Point. (From a survey made in 1587.)

late years by the late M. A. Lower, shows that some of the conclusions arrived at in these papers, touching this part of the coast, may require corrections,[1] especially as regards the Langney shingle beds. This survey (the original of which,[2] on vellum, and in an excellent state of preservation, is in the hands of Mr. Wynne E. Baxter, of Lewes) shows a large tract, marked 'Beache,' where the present shingle beds extend, and

[[1] The conclusions here referred to are confirmed by this Report. Mr. Maddock's paper, was taken from that in the 'Proc. Inst. C. E.,' as regards this part of the coast.—J. B. R., February 1886.]

[2] Another copy is in the British Museum.

even marks 'Langney Pointe,' which, not being marked on Dean Nowell's map, Mr. Maddock assumes not to have been in existence at that date.

It will be best to divide this piece of coast-line into three, as there is a considerable difference in these subdivisions. Going from east to west we have—

(1) The Langney shingle beds, where the shore is composed entirely of shingle in fulls or ridges.

(2) The low cliffs from the sea houses ('Splash Point') to the Wish Tower, composed principally of Upper Green Sandstone, but now obscured by the sea-wall and esplanade.

(3) The chalk cliffs, in most places much higher than the last mentioned, from the Wish Tower to Beachy Head.

In division (1) there is conclusive evidence of waste in recent times, though it is difficult to get any accurate information as to its extent and the rate of erosion. It is, however, quite evident that when the one-inch Ordnance Survey map was first published, in 1813, the Martello Towers numbered 69, 70, 71, 72 were some distance above high-water mark; they are now all destroyed, and only the ruins of two of them laid bare at low water, about half-way between high and low tide.

In division (2), the part between the Sea Houses and the Wish Tower, the evidence of waste is most conclusive. In a paper in the 'Phil. Trans.' for 1717, Dr. Tabor, of Lewes, minutely describes the position of the Roman pavement which had been recently found at Eastbourne. This was at that time '*distant from high-water mark a furlong*. In former times it might have been somewhat more, because from this point to the westward the sea is always gaining from the land.' The position of this pavement is approximately known. It was not more than a few yards from 'Splash Point,' the spot where stood the old house called the 'Round House,' which, being partly undermined by the sea, was pulled down in 1841. We have therefore the fact that between 1717 and 1841 nearly a furlong of land was destroyed by the encroachments of the sea in this particular spot.

Further evidence of this is supplied in the following quotation from 'Homely Herbert's Guide to Eastbourne,' 1857:—

'Immediately beneath where this house [the Round House] stood cattle were wont to feed in a delightful meadow. . . . It is supposed that within the last ten years no fewer than three acres of land have been washed away from hereabouts.'

Further to the westward the sea has also encroached much, as an ex-coastguardsman, who has been in Eastbourne for fifty-eight years, told me of a house which formerly stood east of the Wish Tower, the site of which is now covered with shingle, below high-water mark of highest tides. In front of this house he remembered a 'fair-sized garden,' and he had spoken with a man who remembered playing cricket in a field between this garden and the sea. The bluff on which the Wish Tower stands appears to have offered more resistance to the encroachments of the sea, as in the Ordnance Survey of 1813 it does not appear as such a prominent projection as it now is.

In the third division, from the Wish Tower westwards to Beachy Head, the chalk cliffs are higher, and there is less evidence of waste. Where the sea-wall now extends (as far as the disused chalk quarry at Holywell) there used, five or six years ago, to be sheer cliffs, their base touched by the highest tides, but they do not appear to have been wasting at all fast; while between Holywell and Beachy Head the cliff face is mostly crumbled and overgrown with vegetation, in some places right down to the shingle, showing that there, at all events, little appreciable erosion has taken place for some years.

At Beachy Head itself, the great height of the cliffs rising to 532 feet, and the immense mass which the sea has in consequence to wear down, prevents anything like rapid erosion, and, moreover, the base of these cliffs is, except for 200 or 300 yards at the actual point, composed of the hard Lower Chalk (without flints), which offers great resistance to the sea. It appears, indeed, that the upper part of the cliffs, under the influence of rain, frost, and salt spray, wastes more quickly than the lower from the attacks of the waves, as the latter usually protrudes, allowing the formation of the grassy slopes and green ledges which are the conspicuous beauty of Beachy Head. The occasional falls of the upper cliff slip over the lower strata, and form a talus of chalk ruin, sometimes jutting far enough into the sea to allow the shingle to collect to westward. This protects the cliff still more from the sea. Such a fall occurred about the year 1848, a little westward of the highest cliffs, and its effect in stopping the shingle was so great that the Commissioners of Pevensey Level took steps to hasten its destruction by blowing up the largest blocks of chalk with gunpowder. There

were formerly at Beachy Head three pinnacles of chalk projecting from the cliff top, and known as the 'Three Charleses.' These are mentioned as early as 1717 (in Dr. Tabor's paper before quoted), and though the last remaining fell into ruins in 1852, the bases of two of them still remain, showing how little of the cliff has perished in 150 years.

As to erosion before 1717, it seems impossible to obtain any accurate information. Sir Wm. Burrell (in the Burrell MSS. in the British Museum) mentions a survey of this neighbourhood, made by Sir Edward Burton in 1630, which he had consulted. But the agents of the present owner of Compton Place (the Duke of Devonshire) can give me no information about it, and it appears to be lost. This survey might have been of use if discoverable.

It is noteworthy that Dr. Tabor says that even at the beginning of the last century the sea was '*always gaining on the land*' at Eastbourne.

In Roman work at Pevensey Castle (*i.e.*, as early as the third or fourth century A.D.) unmistakable pieces of seashore rocks are built in belonging to the Upper Green Sand, or the Cretaceous stone immediately overlying it; some are rounded by water, and bear calcareous worm-casts, and some are perforated by *lithodomi*. This shows that as long ago as this date, the sea was washing the beds of the Upper Green Sand. It is, however, difficult to calculate the direction of these beds under the sea. There is no reef now existing hereabouts at any distance from the shore, the furthest being a reef of small rocks about a quarter of a mile from high-water mark, which is exposed at low tides. If this point were capable of being ascertained with any exactness it would afford a satisfactory chronological index.

With regard to the erosion of the whole of this part of the coast, from Beachy Head eastward to Langney Point, the consideration of most importance is the Langney shingle beds. For if we judge by the rate of waste of these beds since 1813, it is plain that they must once have extended some way eastward of their present limits. Additional evidence of this is found—

(*a*) In the Elizabethan survey, 1587, in which 'The Beache' is marked as continuing at least as far as Holywell, and is plainly distinguished from the tide-covered shingle.

(*b*) Camden speaks of 'the promontory called the Beach, from its gravelly beach,' as if the shingle reached actually to the headland in those days (Camden's 'Britannia,' ed. Gough, i. 189).

(*c*) In 1728 the Commissioners appointed to survey the coast of Great Britain say: 'The high ridge of beach runs on to a point of land beyond Bourn west, and there ends; which point, for that very reason, is called Beach Head, or Beachy Head' (quoted in 'Sussex Arch. Collections,' xi.).

The shelter afforded by Beachy Head, and the reef which runs out from it like a natural breakwater, if not the original cause of the formation of these shingle beds, may well have helped in their formation.

The sea-front at Eastbourne is now protected by a sea-wall and a system of wooden groynes, the spaces between which are soon filled by shingle washing from the west.

For some years past, in front of the Wish Tower, it has been the practice to allow rocks of the Upper Green Sandstone to be removed, and whole reefs, about half-way between high and low tide, have been thus removed. The authorities say that the removal of these rocks has greatly facilitated the washing up of the shingle into the groynes. But it is noticeable that where a large reef has been removed in the last few years, it has lately been found necessary to defend the sea-wall with a series of strong groynes set closely together.

D.—The Coast of East Kent.

By GEORGE DOWKER, F.G.S., Stourmouth, Wingham, Kent.

The district to which this Report refers is comprised within a line from Dover to Whitstable to the west, and the parts of Kent east of that line.

The shore line from Dover to Walmer on the south is composed of Chalk cliffs, containing flints, and ranging in height from two hundred feet to fifty; from Walmer to Deal, of clay, about twenty feet; from Deal to Pegwell Bay, of low marshes, raised towards the shore by the sand-hills, averaging about fifteen feet, and a sea-beach.

At Pegwell Bay are low cliffs of marly 'Thanet Beds,' which are succeeded by nearly flintless Chalk cliffs (in the bay), except the junction-bed with the Tertiaries, which contains numerous nodular and tabular flints. There are also large tabular Sandstone blocks, which occur in the Tertiary bed, and which are termed 'moorlogs' in the Ordnance maps. It is at this point that the present mouth of the Stour discharges its waters into the sea.

The remaining eastern coast-line from Pegwell to the North Foreland consists of Chalk headlands, about fifty feet in height, containing, for the most part, tabular and nodular flints.

The sea opposite the before-mentioned coast-line is called the 'Downs,' and at some distance from the shore are the dreaded Goodwin Sands, and numerous shoals that divide the tidal currents. The prevailing, or most rapid, current runs from south to north along this line of coast.

The northern shore-line from Whitstable to a little beyond Herne Bay is composed of London Clay cliffs, which vary from forty to seventy feet in height. From Beltinge (east of Herne Bay) to Reculvers the lower part of the cliff is composed of sand, with occasional Sandstone blocks, the latter more numerous towards Reculvers. From this point eastward, as far as Cliffend, at Birchington, the shore is a marsh below high-water line, protected by artificial embankments.

From Birchington to Foreness, near the North Foreland, the cliffs are of Chalk, nearly devoid of flint, ranging from thirty to fifty feet in height.

The sea opposite this northern shore consists of the mouth of the River Thames, which has numerous shoals, the largest and most remarkable of which is known as the 'Margate Sand,' being of a like character with the Goodwin Sands, to the south of the Isle of Thanet. The tidal current runs east and west; strongest from the east.

Sea-Beaches.

On the southern shore of this district are sea-beaches, for the most part underneath the cliffs, and piled up along shore, so as to form a natural barrier to the waves. These beaches have been travelling, and are still travelling, from the south towards the north. Artificial barriers across these beaches, at right angles to the shore, arrest this action, but the tendency of the sea-current is always to sweep round such obstructions, and the impinging force in such cases carries away the beach which had accumulated to leeward.

At Dover the construction of the Admiralty Pier has caused the beach to accumulate to the south-west, and, by the sweeping round of the tide, to remove the beach to the north of the town. A great change is perceptible in this respect since I have known the coast.

At St. Margaret's Bay the beach has diminished, and between here and Kingsdown a large quantity has been swept away during the last few years. Towards Walmer there has been a large accumulation, which is now rather stationary.

To the north of Deal and towards Sandown Castle the shore is being rapidly cut back. The beach alone here forms a natural barrier, and protects the low land behind it. Any cause tending to weaken or destroy this would cause the sea to inundate the Lydden Valley, some hundreds of acres in extent. The sand-hills beyond form a like natural protection.

In times past, the accumulations of sand blown on shore by the south-westerly winds have caused gain of land from the sea. At the same time, the prevailing currents have thrown back the mouth of the Stour more and more to the north, which has further gained from the sea a tract of land now protected by the sand hills.

At Pegwell Bay the sea has gained greatly on the land, washing away the cliff at a rapid rate, as my sketches taken here in 1849, 1868, and 1884 show.

From Ramsgate Harbour to the North Foreland, the shore below the cliff is covered with sand at high water mark, and there is little or no beach. Some falls of cliff have taken place, but the shore has not been materially cut back since I have known it.

From Walmer to the North Foreland there are very few groynes, and beach has been largely abstracted at different times artificially. Though some of the local authorities have prohibited this removal, it still goes on at places. Such removal must be prejudicial in exhausting the supply of material moved by the sea.

The *northern* shore of this area has comparatively little beach, and its removal should be strongly opposed. From the Foreness Point to the extreme end of the

Chalk cliff west of Margate, the fall of cliff has been very insignificant, and no flints, or very few, can be derived from this source.

Between this point and the Reculvers the marsh is protected by numerous groynes, kept up at great cost by the Commissioners of Sewers, which have been instrumental in keeping back the sea.

The London Clay cliffs along the remaining portion of this northern shore have suffered great denudation and destruction by the waves. There are some beaches below the cliff, derived, in part, from the gravel beds on the top of them.

The sea currents do not run so strong along this as on the southern shore of the area.

Coast-Changes.

There are evidences, both physical and historical, that relate to very great changes within this district. The Isle of Thanet, as its name implies, was once separated from the mainland by an arm of the sea, which has greatly been recovered from the ocean within the historical period.

I have not been able to discover any evidence of changes in elevation or depression within this area since the Roman occupation of England.

The estuary of the Wantsum, the river that separated the Isle of Thanet from the mainland, has been recovered from the sea, partly by human agencies, and in great measure by the silting up of the river, caused by the sea-currents diverting its mouth in a northerly direction, by the travelling of sea-beaches, and by accumulation of blown sand.

The Roman Rutupean ports and castra of Richborough and Reculvers were undoubtedly accessible to the Roman fleets.

Maps relating to the district, from the time of Queen Elizabeth, all show that the changes now taking place along the coast-line have all been acting in one direction, viz. a shifting of the strength of the tidal current from the south towards the north.

Between Sandwich and the Isle of Thanet an old sea-beach is situated, on one extremity of which was erected the ancient town of Stonar; the material of which it is composed shows it was derived from material brought from the north. The present sea-beaches from Dover to the North Foreland, on the other hand, are derived from material carried from the south.

There is no historical or other evidence to show that this beach has accumulated or been in process of formation during the period dating from the first century. But, rather, it would seem that it was not covered by the waves during the Roman occupation of Britain. I believe it was formed long anterior to that event.

If I am not mistaken, a similar alteration in the great tidal wave that sweeps round the coast of Britain can elsewhere be traced. And the removal of ancient land-barriers must have played an important part in these operations.

I am preparing a full Report upon this district, of which this must serve as a short abstract.

I have consulted the Reports made from time to time to the Admiralty Naval Department; Reports from the Board of Trade in reference to the beach at Deal; Mr. Redman's Essays on the Alluvial Formations and Local Changes on the South Coast of England; an Historical Report on Ramsgate Harbour by John Smeaton, 1791; various Reports on the south-eastern district prepared for your Committee; and all available archæological works relating to the subject, a list of which will accompany the full Report.

A tracing of the one-inch Ordnance Map accompanies this Report.

---

1. Sidmouth.

By Peter Orlando Hutchinson, Old Chancel, Sidmouth, Devon.

1. Sidmouth and neighbourhood best, having resided mostly there since January 1825.

2. The cliffs reveal a fine section of the Trias, extending from Axmouth on the east (with a small interruption at Beer Head) to near Babbacombe on the west, a distance of 19 miles. **a.** The Red Marl at Sidmouth; but as the strata rise

towards Dartmoor, the cliffs towards Exmouth, Dawlish, &c., are composed of the Lower beds of Sand rock and coarse conglomerate. **b.** The height of High Peak, the second hill west of Sidmouth, by the Ordnance Survey, is marked as 513·9 feet high, reduced to mean tide, Liverpool. Peak Hill, next on the west from Sidmouth, is 439, and Salcombe Hill, east, 497 by the barometer. Though flat on the top, the high land rises inland, or northward, towards Blackdown, at the rate of about 50 feet in a mile.

3. From Beer Head to Sidmouth nearly east and west; farther west it curves round to the south-west and south towards Torbay.

4. In January and February either north wind and frost, or south and west with storms and rain. March, April, and part of May much cold north-east wind. June often showery, with westerly winds. July, August, and September, if not disturbed by thunder, steady north-west wind and fine weather. October equinoctial gales from south and west, with rain. November has generally a ten days' spell of frost. December often milder.

5. The south-west wind brings the highest waves, which come up Channel from the Atlantic. The south-west wind piles up shingle at Sidmouth, and the north-east winds clear it away. The shingle on this part of the coast seems to travel east or west according to the direction of the wind.

6. The tidal currents are intricate and varying, and change as the tide is rising or falling. The fishermen are not always clear on the subject. I am disposed to think that when the tide is rising, and the current running eastward in mid-channel, it strikes against Portland and turns back by a great eddy and runs past Sidmouth in the opposite direction. When the tide falls the currents are reversed, and every headland has its eddy.

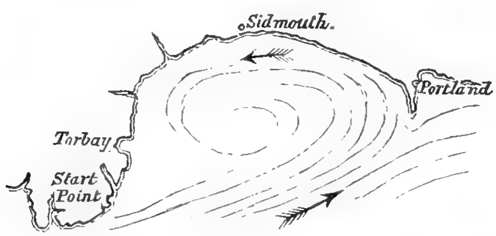

FIG. 2.—Eddy between Start Point and Portland—the tide rising.

7. (1) I have no trustworthy information on this point, and the local fishermen and sailors differ in their statements. It could easily be ascertained in calm weather. For the present I may observe that 12 to 14 feet is likely to be near the truth. The highest and lowest spring tides occur at the equinoxes. (2) This depends on the steepness or slope of the beach, which is steeper near high-water mark than low. On an average about 35 yards at Sidmouth.

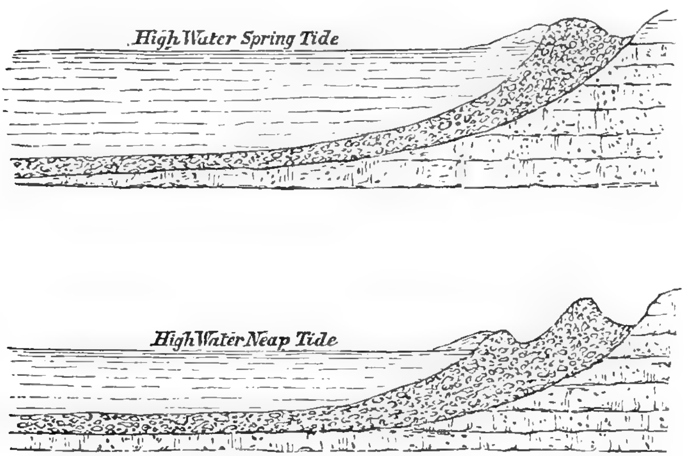
8. For miles on each side of Sidmouth it consists of chert and flint shingle, fed from the clay and flint bed capping the tops of the hills over the Greensand. At low water a flat sand is uncovered in some places. A low reef of rocks runs into the sea immediately on the west of Sidmouth, and is called the 'Chit Rocks.' They begin to uncover at half-tide down. No mud, but fine sand, called 'mud-sand.'

9. a. From the cliffs, or from the esplanade wall of Sidmouth (about 1,841 feet long), down to the beginning of the sand, the average width of the shingle is 35 yards. **b.** They cover the whole beach everywhere, the pebbles being from the size of peas to the size of the fist. **c.** The shingle travels east with a west wind, and west with an east wind. **d.** According to the size of the flints, some may be as large as a child's head. **e.** The shingle forms a curved slope (Figs. 3 and 4), but at high-water mark the waves throw it up into a ridge more or less high.

10. Curiously enough, the shingle seems to accumulate and to diminish by cycles—perhaps irregular, for I have no record of these changes. I remember a great accumulation of shingle, I think about 1847, and six or eight years after a considerable diminution. Again, about 1860, or soon after, it was heaped up so high as to be above the esplanade wall. It decreased till 1873, and by

January in that year it had become so cleared out, that from Belmont to the Chit Rocks, at the western end, the red rock was bare, and an extent of clay and river sand was exposed opposite Fort Cottage. Since then it has been returning.

11. This remarkable diminution had never been seen before, and caused great surprise. It was due to natural causes. The River Sid once had an outlet to the sea where Fort Cottage stands, as a bank behind the cottage shows, and which I have traced through the town inland. When the shingle was all cleared away, the surprise was increased by the appearance of a number of stumps of trees dotted about the beach between high and low water, and when the tide was in they were from 4 to 5 feet under water The stumps were worn short off, but they were evidently *in situ*, for on digging round some of them, which I did with others, the roots were found to radiate in the clay. They were of alder. I have several specimens. Also in the clay, probably washed down the river, five or six Mammoth teeth were found, most of which I secured. Three or four of the best I have given to the Exeter Museum.



Figs. 3 and 4.—Diagrammatic Sections through a Shingle-Beach.

12. In 1830 a number of groynes were made all along the beach in front of the town of Sidmouth, as an experiment, to see whether they would accumulate and retain the shingle. I saw many of the piles driven and much of the work done. **a.** They were carried out at right angles to the shore line, or line of the Parade, or Esplanade, as commonly styled. The Esplanade then was merely a walk on a bank of earth. The Esplanade wall, which is about 1,841 feet long, was not built till 1837. **b.** The length of the groynes, from their starting-point at the Esplanade, was about 30 yards, that is nearly to the commencement of the sand at low water. **c.** Judging only from recollection, I should say they were about 200 feet apart. **d.** Their height when built was about 5 feet at the inner end, and 3 or 4 feet at the farthest end. On the leeward side no shingle accumulated, but it became heaped up on the windward side. When the wind changed, say from west to east, the shingle was heaped up on the east, or new windward side, and cleared away from the west, or previous windward side, but new lee side; and when the wind was end on it was cleared away on both sides altogether. **e.** They were made of elm timber, to the best of my recollection. The piles were about 7 or 8 inches square, and perhaps 4 feet apart, and they were planked on both sides with stout elm boards some 2 inches thick. **f.** They disappointed the builders. They accumulated small portions of shingle in places, but wholly failed to retain it. When the gales of wind were strongest, and the waves were the highest and most violent in their attacks, and when the protection of a bank of shingle was wanted for the esplanade, and, indeed, for the sea-front of the town, then it got either washed away or got drawn back into deep water. After a few years' wear and tear the groynes began to show signs of dilapidation,

but as they were evidently useless for the purpose intended, they were left to their fate, and in a few years more they were either destroyed by the waves or utilised by the fishermen for firewood. They having failed, the esplanade wall was built in 1837.

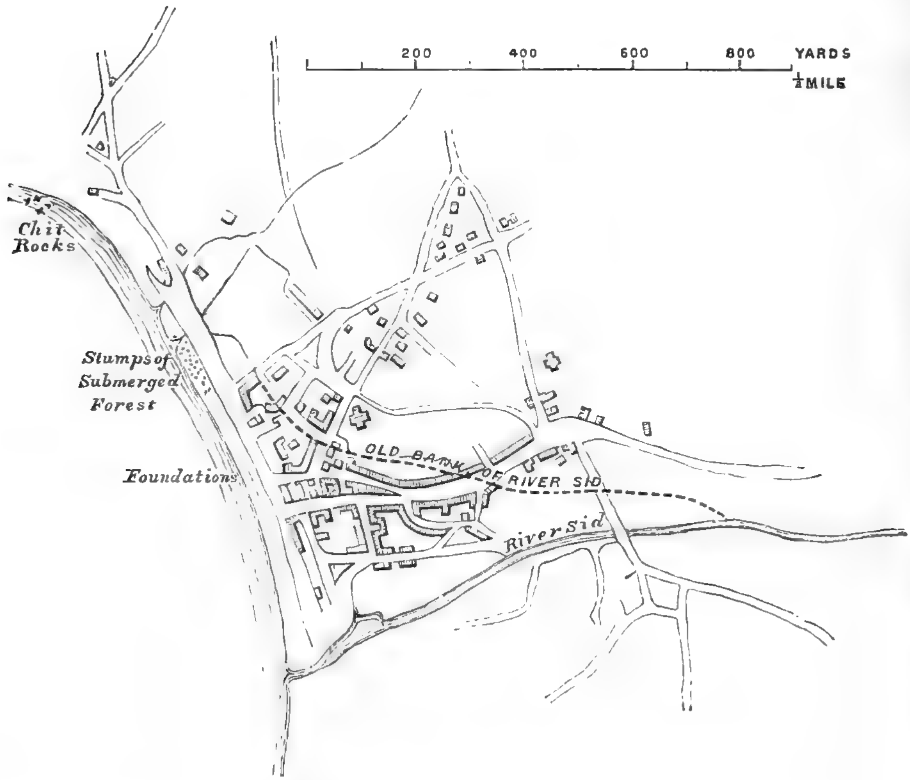


FIG. 5.—Plan of part of Sidmouth, showing the old river bank.

13. It has always been the custom at Sidmouth for the inhabitants to take sand and gravel from the beach. About 1870, speaking at a guess, the Board of Trade set up a new claim to the foreshore, and forbade such removal, but there was such a rebellion in the town that they dropped it. **a.** The material is taken from anywhere between high and low water mark, according as coarse or fine material is wanted. **b.** Gravel is used for gravel walks and roads, and many persons earn a living by fetching it when other business is slack. Sand of the coarser kind is used by the masons and others for mortar, cement, and various other purposes; but when this was forbidden, building was stopped, which not only affected the masons, but it concerned the carpenters, plumbers, painters, glaziers, &c., and hence the rebellion. **c.** All persons are free now to take any material they want from the foreshore, though the Board of Trade claims waifs and strays and certain large fish; but though this claim is new, it is not resisted. It was once enjoyed by the lords of the manor, for I have a lease granted by Henry VIII., in which it is mentioned; but the lords of the manor have neglected it. The small amount of material taken from the beach can have no effect whatever. The reef of rocks at the west end of the beach (the Chit Rocks) is too low to act as a natural breakwater, except at low tide.

14. a. and **b.** This is an interesting question and comprehends a great deal. I have been watching the wearing away of the cliffs from boyhood, and see great changes. The greatest loss is in the soft red marl from Axmouth to Sidmouth, and next in the sand-rock farther west to Exmouth, though hard patches of conglomerate occur in places. There is no regularity in erosion, for the softer

parts go fastest; and the waves attack the bases of the cliffs, and this brings down the upper portions. **c.** The rate of erosion in South Devon must be various. Perhaps I may say an inch a year for the last fifty years, which I remember; there are soft places in the cliffs that have gone twice or three times as much, and harder parts not half as much. **d.** I know of no old maps of sufficiently large scale or sufficient accuracy to determine changes of coast. Donn's (or Don's) map occurs to me, but it would be useless. **e.** The loss goes on everywhere, irrespective of shingle.

15. The questions under this head are virtually answered under **12** and **13**, as far as I am able. I will, however, here mention a circumstance which was told to me, at which I was rather surprised. When the esplanade wall was built in 1837, one of the coping stones towards the west end was trimmed after it was in position, and the chips fell several feet down, the shingle then being low. The south-west gales of wind during the winter after carried the shingle up to the top of the wall to the coping (6), but instead of burying the chips, my informant declared that they must have been lifted or forced up, for they were lying undisturbed on the top of shingle (6), and close to the coping stone. On inquiring how he could account for so strange a circumstance, he said he supposed that the pounding and beating of the heavy waves must have forced the shingle up bodily, and thus lifted the chips. I may add that I had not the opportunity of seeing the chips there myself.

16. No land is being gained from the sea along the coast of South-east Devon, but the contrary. The silting-up of shallows within the mouths of rivers, and the forming of mud banks, and eventually meadows, can scarcely come under this head. This latter process has given meadows within the mouths of the Sid at Sidmouth, the Otter at Budleigh Salterton, and the Axe at Axmouth. Silting-up is going on in the Exe, the Teign, &c., and eastward in Poole harbour, &c.

17. As the beach in South-east Devon, from Lyme to Exmouth, is composed of pebbles, and as high cliffs rise immediately from the beach nearly all the way, there is no blown sand there. There is, however, an expanse of sand a mile and a half wide at the mouth of the River Exe, occupying the width of the estuary, open to the sea and open at the back up the estuary. The seabeach is almost entirely of sand, and this expanse, called 'the Warren,' is composed of blown sand and estuarine accumulation, and all along the sea front there is a long ridge of sand dunes, between 20 and 30 feet high in some places. The waves in winter sometimes make breaches in this ridge, and the Mayor and Town Council of Exeter, who have rights here, have consulted engineers, fearing that the anchorage inside would be thrown open to the sea. But I think there is no danger. The features of the Warren may alter, and the sand will shift, but the reparations by blowing are always going on, so that I do not apprehend total or permanent destruction. Indications have been discovered of late years which go to show that the Exe once had an outlet under Mount Pleasant. Out of reach of the sea the sand is overgrown with bent grass, rushes, &c. And here is found the *Trichonema bulbicodium* (or *T. columnæ*), a small plant with a bulb about the size of a pea, belonging to France and the Mediterranean, supposed to have been thrown up by the sea. The Exmouth Warren is the only known habitat in Britain.

18. Many excellent papers on the Geology of South Devon have been written, though not exclusively devoted to the coast. There is not room to give full titles here. Besides the larger books, the following papers have come under my notice:—H. B. Woodward, Quart. Journ. Geol. Soc. 1876, p. 230; Geol. Mag. 1877, p. 447, &c. W. A. E. Ussher, Geol. Mag. 1875, p. 163; Quart. Journ. Geol. Soc. 1876, p. 367; Ibid. 1877, pp. 49, 449; Trans. Devonsh. Assoc. vol. x. p. 203 (On the Mouth of the River Exe); Ibid. vol. xi. p. 422; Ibid. vol. xii. p. 251; Aubrey Strahan, Esq., also of the Geological Survey, has a good knowledge of Sidmouth. Rev. W. Downes, of Kentisbear, Quart. Journ. Geol. Soc. 1882, p. 75, and many papers in Trans. Devonsh. Assoc. on the Blackdown Hills and Mid-Devon Geology. G. W. Ormerod, Teignmouth, Quart. Journ. Geol. Soc. 1867, p. 418; Ibid. 1869, p. 273; Ibid. 1875, p. 345 (Estuary of the Exe), &c. H. J. Johnstone Lavis, Ibid. 1876, p. 273, on Labyrinthodon. A. T. Metcalfe, Ibid. 1884, p. 257, being more about the Labyrinthodon. P. O. Hutchinson, Trans. Devonsh. Assoc. vol. xi. p. 383 (Fossil Plants in the Red Marl); Ibid. vol. vi. p. 232 (Submerged Forest).

19. There is one point on which I wish to make a remark, and that is, the universally prevailing opinion among the seafaring people on the south coast, that the sea is gaining on the land. This belief prevails at least from Portland to the Scilly Isles. Such a change can take place in two ways: one is, that the cliffs are receding before the waves, and the other is, that the land is going down. I have said above, at No. **14**, that the land is being worn away by the sea; and I may add that for twenty years past I have had a growing conviction that the land is going down. Not only does the sea appear higher and fuller than it used to do at high water, and points of land harder to go round at all times of the tide than when I was a boy, which signs, however, are not conclusive, but I have alluded to the submerged forest, and I may also allude to 'the foundations,' as some massive stone walls are called, supposed once to have been a habitable building, and within my memory generally uncovered, but not now. They are under the shingle, 30 feet outside the esplanade, and opposite Marlborough Place and Portland House. Like the stumps of trees, they are several feet under water at high tide. As to the rate of subsidence, I have thought that 10 inches in 100 years would be enough. In 800 years, or since the Norman Conquest, that would be 10×8 inches $= 80$ inches $= 6$ feet 8 inches. If the foundations and the trees were 6 feet 8 inches higher at the Conquest they would have been above the water, and the coast-line some distance farther out.

---

2. Lyme Regis and Charmouth.

By RICHARD B. GRANTHAM, F.G.S., M.Inst.C.E., 22 Whitehall Place, London.

1. I have had occasion to examine the part of the coast of Dorsetshire lying between the town of Lyme Regis and the valley of the Char, near Charmouth.

2. Commencing from the west, along the cliff from Lyme Regis, the cliff consists of the Lower Lias Clay and Limestone, at first about 40 feet high, and at the highest part it rises to about 300 feet, and consists of blue Lias clay, capped with chert gravel, which is above the Lias, and overlies the Greensand. The cliff then descends to the River Char, and from the river eastwards the same formation appears on the cliffs, but they do not here exceed 50 to 70 feet in height. The land rises inland from the cliffs, but not very much. The shore as far as low water consists of thin beds of Lias rock, dipping slightly towards the east and seawards, and is the base of the cliffs. Water percolates from under the chert bed and Greensand, and finds its way down to the Lias beds, and appears on the face of the cliffs, and causes them to slip in large masses by degrees into the sea. This refers to the cliff where it is 300 feet and upwards in height.

3. The direction of the coast-line, after leaving the town of Lyme Regis, forms a bay bearing eastwards, and then curves back inland and continues east by south.

4. The prevailing wind is from the south-west, and is probably the cause of heavy seas.

5. There is no shingle.

6. They run up Channel towards the east and back to the west. The set of the tides between Beer Head and Portland Bill for eight miles east of the former is very various, and up to the latter is also extremely complicated and most difficult to describe. (See the 'Admiralty Tide-tables,' page 109.)

7. (1) The tides rise between Lyme Regis and Bridport $11\frac{1}{2}$ to $11\frac{1}{4}$. The neap tides rise in the same distance from $8\frac{1}{2}$ to $7\frac{3}{4}$. (2) The width varies from 200 to 230 yards at the mouth of the Char.

8. It consists of bare rock, as before described.

12. There are no groynes or shingle.

14. I could get no information as to the erosion or its position, and there are no local points to judge from.

16. Generally, along this coast there are no means of judging of any increase of land.

---

3. Axmouth to Eype.

By HORACE B. WOODWARD, F.G.S., Geological Survey of England,
28 Jermyn Street, S.W.

1. Devonshire and Dorsetshire. Axmouth to Eype, west of Bridport.

2. The eastern cliffs, of which the highest point is Golden Gap (620 feet), are composed of Lias Clay and shale, capped by sand. Between Charmouth and Pinney the base of the cliffs is stone with clay above; the summit here is Black Ven (450 feet), where there is again a capping of sand. Between Pinney and Axmouth the sea-cliffs, of Red Marl, range up to about 60 feet; they are backed by high cliffs and undercliffs.

3. Axmouth to Charmouth, N.E. and S.W.; about E. 22° N. Charmouth to Eype, N.W. and S.E.; about W. 15° S.

4. South-west.

5. Lyme Regis—severe storm in 1824, after strong westerly winds; then gale arose from S.S.E.; wind veering to S. and S.W., drove the heaped-up waters directly on coast. Seatown, very changeable beach. Shingle mostly heaped up in fine weather; more sand after a north wind; a south wind pulls back the shingle. South-west wind, heaviest sea. South-east wind, highest tides. Lyme Regis, west of Cobb—south-west wind fills up beach; south wind draws off beach.

6. Flood tide from west, up Channel. Various local currents. Tide runs a good deal stronger up stream than down.

7. (1) 25 feet (maximum); 12 feet (Charmouth); 14 feet (Lyme). (2) 25 to 30 yards (Seatown); 300 yards (Charmouth), platforms of rock.

8. At high tide, sea dashes up against cliffs, east and west of Lyme Regis. Mostly fine shingle and sand, with patches of coarser shingle. East of Charmouth, a good deal of sand for a short distance, then all shingle to Golden Cap. Ledges of rock at low tide just west of Golden Cap. Black Ven, sand and ledges of stone and clay. Lyme Regis to Axmouth, here and there bays with shingle, otherwise tumbled material—large blocks of Lias and Greensand-chert, Chalk, &c., ledges of rock; nearer Axmouth, shingle with patches of sand at low tide, on platform of Red Marl.

9. a. and **b**. Beach of shingle, about 30 yards wide, at Seatown, *above* ordinary high-tide mark. Beach of shingle, about 22 yards wide, west of Golden Cap, *above* ordinary high-tide mark. **c.** *Generally* from east to west, being heaped up on *west* sides of slips. Some twenty or thirty years ago, after a great landslip at Golden Cap, the travelling of shingle was stopped for some time, and the sea dashed up against the Lias cliffs to the east, where usually there is a shingle beach that protects them. **d.** Seatown, mixed shingle, 2 to 5 or 6 inches, intermingled with fine shingle; 8×4 inches, many $3 \times 1\frac{1}{2}$ inches and less; chiefly flint and chert, some quartzites; a few slabs or flat pebbles of Lias; hardly ever any fine sand at Seatown. West of Golden Cap, 6×4 inches, many $2\frac{1}{2} \times 2$ inches, &c.; shingle rather smaller towards Charmouth—*westward*. **e.** Highest ridge at Seatown about 30 feet above low tide; lower ridge, 10 or 12 yards distant, 25 feet above low tide; spring tides do not usually come above this. West of Golden Cap, November 1884, highest ridge about 23 feet above low tide, extends 10 yards from cliff; second ridge about 15 feet above low tide, 12 yards from higher ridge, and about 30 yards from foreshore. East of Seatown the beach is almost entirely shingle as far as Down Cliff; it is 20 feet high in places.

10. Accumulates or diminishes according to wind and tides.

11. No.

12. A few in Lyme itself, to protect buildings inside bay formed by Cobb. **e.** Stone. **f.** To check the force of the breakers.

13. a. Stone taken from cliffs and ledges, east and west of Lyme. **b.** Lime, and chiefly for cement. About 10,000 tons sent to Hull for docks in one year. Amount varies according to demand. **c.** Yes. **d.** *Yes*; especially at base of Church Cliffs, east of Lyme. The church itself is now in considerable danger, the churchyard being at edge of cliffs. Shingle carted away at times from beach at Seatown for road-metal, but not from Charmouth.

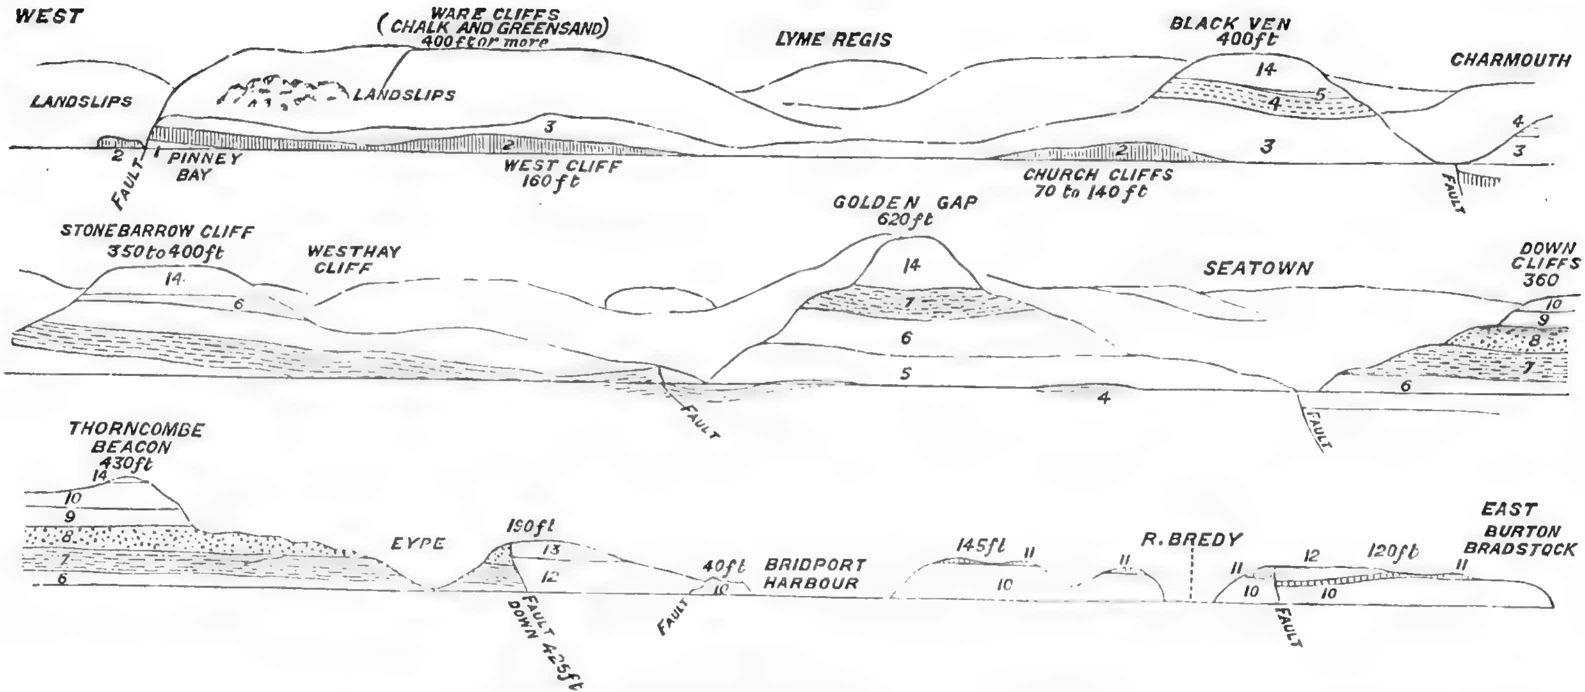

FIG. 6.—Sections of the Dorsetshire Cliffs. By H. B. Woodward.

Rhætic Beds	1. Limestone (White Lias).
Lower Lias	2. Limestone (Blue Lias).
	3. Clay.
	4. Marl (Belemnite Beds).
Middle Lias	5. Clay (Green Ammonite Beds).
	6. Clay { Clay. Three Tiers (stone).
	7. Sand and clay.
	8. Sand.
Upper Lias	9. Clay.
Inferior Oolite	10. Sand with indurated bands of sandy limestone.
	11. Limestone.
Fuller's Earth	12. Clay and marl.
Forest Marble	13. Limestone and clay.
Chert gravel, Upper Greensand and Gault	14. Sand and gravel.

Horizontal Scale about one and a half inch to one mile. Vertical Scale much exaggerated.
(These sections are published by permission of the Director-General of the Geological Survey.)

14. Cliffs, on the whole, are destroyed chiefly by slips, and the sea clears aways the *débris*. More especially just east and west of Lyme Regis—the lower Lias limestones, aided largely by the artificial removal of stone. Thorncombe Beacon : base of cliffs protected by large tumbled blocks of stone ; hence a slight headland is formed. Thorncombe Beacon was formerly much higher, according to men living in the district. Golden Cap protected by huge blocks of stone which have fallen from cliffs, also by ledges ; hence it forms a slight point or headland. Golden Cap, in the opinion of fishermen, has been lowered 30 or 40 feet during the past 30 or 40 years. The lowering of Golden Cap has been caused partly by reason of the hill-slope inclining inwards, and perhaps partly by streams carrying away sandy material at the junction of Greensand and Lias. West of Charmouth, a field of 5 acres about 150 years ago, now $1\frac{1}{2}$ acres. East of Charmouth, man aged about 75 (died about 10 years ago) knew when 'they went out milking where the beach now is.' Field reduced from 10 acres to 4 acres ; not gone much since. This field was evidently based on portions of an old slip, as, when removed, portions of old trees and shrubs were laid bare again. Oak-wood out of river-bed, ebonised and black as ink, sold for turning at the time. Seatown : road and four or five houses have gone on west side of river during last twenty years, owing to slips. One cottage gone by coast just east of river at Seatown, and man named Foss, innkeeper, æt. 84, says he dug portions of piles out of river, but the oldest inhabitant he remembers never heard of there being a harbour there, although the piles seemed to prove that such had been the case. Limekiln and road at Stonebarrow (about 50 yards) put back twice, and gone in last 60 years, and field of 11 acres (60 years ago) now 4 acres. The sea formerly (*i.e.*, 50 or 60 years ago) used to wash up against the cliffs of Stonebarrow ; now it only reaches them at extraordinary tides. Hence cliffs are not worn away so fast as formerly. If the cliffs were drained, there might be fewer slips, and hence the land would be protected. Lyme Regis, Church Cliffs : Lower Lias clay on limestone lost 90 feet in 30 years (1803–1833) (G. Roberts), partly by gradual mouldering and crumbling, without any great 'slide' or landslip, and partly owing to the removal of stone from base of cliffs and shore ; even the very *ledges of the shore were stripped off*, and this is the case now (H. B. W.). Roberts mentions that 'Table Rock' and the 'Horse Pond' are no more—ledges and hollows familiar to him in the early part of this century. He estimated the loss of the cliffs at 3 feet per annum in the soft strata, and 1 foot per annum in the harder rocks. There is still a soft ledge called Table Ledge under Black Ven (H. B. W.). Black Ven is subject to great slips. Roberts says (1834) three fields have gone during the past 100 years ; 90 years previously there was a lane from Lyme Regis to Charmouth, which has almost entirely disappeared. West of Lyme Regis, extensive landslips—Whitlands, 1765 and 1840 ; Bindon (or Bendon) and Dowlands, Christmas 1839.

16. No.

17. No.

18. Roberts, G.: 'The History and Antiquities of Lyme Regis and Charmouth.' Ed. 1, 1824 ; ed. 2, 1834.

19. I was informed by fishermen at Charmouth that a platform of rocks extended from Portland to Start Point, and this extended to about 10 miles distance from Charmouth ; beyond, the sea-bottom was mostly sand. On this platform there were accumulations of shingle (coarse and fine). On this subject, see Prestwich's paper on the Chesil Bank ('Proc. Inst. Civ. Eng.,' vol. xl. p. 61). I was also informed that at Seatown there was a fearful ground-sea on Friday, April 24, 1868, and that it raised the bank of sand and shingle 5 feet, and it so remained. The night before, there was an earthquake at St. Heliers.

---

4. Bridport Harbour, &c.

By Horace B. Woodward.

1. Dorsetshire. Bridport Harbour or West Bay, Eype to Burton Bradstock.

2. Varied. Between Bridport Harbour and Burton Bradstock the cliffs are chiefly Sands with indurated bands ; to the west of Bridport Harbour and to the east of Burton Bradstock the cliffs are chiefly Clay and shale. Cliffs vary from 40 to 190 feet in height.

3. North-west and south-east. W. 30° N., and E. 30° S.
4. South-west.
5. a. South to south-west. **b.** South and south-east on east side of harbour; south-west on west side. **c.** South-west.
6. Flood-tide from west up Channel. There is an eddy-tide from the east on shore for two or three hours during flood-tide, and an eddy-tide on shore from the west during ebb-tide, two or three hours.
7. (1.) **a.** About 13 feet. **b.** From 3 to 5 feet. North-east winds reduce the height of the tide.
8. Fine shingle, with here and there patches of sand at low tide. From Bridport Harbour to Eype, the area is subject to frequent changes, being sometimes for the most part sand, at others for the most part fine shingle; this I have noticed during the month of August 1884. Below East Cliff, benches of bluish sandy limestone are exposed when the beach is uncovered; the top ledge would be about 16 feet above low-level spring-tide. Ledges or reefs of the same rock (indurated bands in the Inferior Oolite *Sands*) are generally exposed at low tide just to the west of Bridport Harbour.
9. a. About 20 yards at Eype. **c.** South-east. **d.** $\frac{1}{4}$ to $\frac{1}{2}$ inch diameter, near Bredy river mouth; occasional large blocks of stone, locally derived.
10 and **11.** Not to any appreciable extent.
12. No.
13. Fine shingle, removed from beach. **b.** Chiefly for ballast for vessels. Used also for ballast on new railway to Bridport Harbour, for platforms of stations, also for footpaths. (Sand is also procured occasionally for mortar, and pebbles are obtained *occasionally* for concrete, but only to a *very limited* extent.) **c.** Tract to east of River Brit belongs to General Pitt-Rivers, that to west belongs to the Earl of Ilchester. They are Lords of the Manors, and the ground is let out on lease to private individuals, who cart away the shingle, &c. The Harbour Commissioners have also certain rights to dig shingle. I am told by the Harbour-master, Mr. Martin Joseph Briggs, that 10,000 tons, which might be taken away in six months, would be replaced perhaps in one tide. He considers that no damage is done to the coast by the artificial removal of shingle.
14. c. East cliff, about 1 foot a year; sands and calcareous sandstone (Inferior Oolite Sands). West cliff, about 1 to 3 feet a year; chiefly clays and marls.
17. e. Blow over gardens and accumulate under walls at back of shingle.

---

5. Weymouth.

By Bernard Henry Woodward, 80 Petherton Road, Highbury New Park, London, N.

1. Weymouth, north of town.
2. Shingle beach, bordering Alluvium, from about 3 furlongs north-east of St. John's Church, Weymouth, to the south of Jordan Hill. Oxford Clay cliffs at either end of shingle bank.
3. North-east and south-west.
4. South-west.
5. a, b, and **c.** South and south-east.
8. Chiefly shingle. Peaty alluvium exposed by mouth of stream south of Jordan Hill.
9. Tendency to travel south-eastward and inland; the road that borders the shingle beach having been 'put back' 60 feet during the last thirty years.
10. Diminishing.
11. Not allowed to be taken away now, although formerly the shingle was carted away.
12. Blocks of Portland rock are placed along shore to protect coast. Groynes were washed away in March 1883.
14. Oxford Clay cliffs below Jordan Hill are subject to most waste after a long dry season, when great cracks or fissures are made in the clay. Then autumnal rains, or winter rains and frost, act with great destructive power.

16. The shingle beach has probably dammed up an old tidal estuary, now the Alluvium of Lodmoor. And, further south, the chief part of Melcombe Regis, Weymouth, is built on marine sand and shingle which has contracted the mouth of the River Wey, and left a kind of broad, known as Radipole Lake or the Backwater. The water in this is now artificially retained at low tide by a weir.—[H. B. W.]

18. See R. Damon: 'Geology of Weymouth, &c.' Ed. 2, 1884.

---

6. Christchurch to Poole.

By the Rev. G. H. West, Ascham School, Bournemouth.

1. Hants and Dorset—Christchurch to Poole.

2. Sandy. **a.** Sand and Clay cliffs. **b.** (1) ? 90 feet. (2) 70 to 80 ?. (3) About 15.

3. North-west to south-east.

4. South-west and west-south-west.

5. a. South-east is the only wind which can bring rollers in, as Studland Point shelters from the south-west. **b.** East wind. The shore is always shingly after east winds, which seem to check the 'travel' of the beach. **c.** Westerly winds, which coincide with the prevailing currents and flow of the tides.

6. There is a strong indraught (marked on Admiralty charts) along shore from Old Harry to Poole, but the main set of the tide is from Old Harry *straight* to Double Dykes (Hengistbury Head). There is also a strong current all along shore eastwards, especially at the second flow, which runs in a sort of fleet, cut off from the open sea by a sandbank. This is attributed, probably correctly, to the ebb from Poole Harbour, which, instead of running straight out to sea, flows out along shore through two openings called the 'Looes.' The general run of the tides here is—flow for about seven hours, then ebb for an hour, fall about nine inches; flow again for one hour and a half up to, or at *neap* tides higher than, at first. At spring tides the proper first flow and ebb are the highest, and the second flow is hardly perceptible. This second flow is generally attributed to the ebb from the Solent, but I do not believe this cause is sufficient. Besides, the tides appear to be very irregular all the way to Weymouth, and on the opposite side in the Baie de la Seine, high water lasts three hours (at Havre). Does not the old tidal-wave, which has been round Scotland, come back through the Straits of Dover and meet the up-Channel wave, being heaped up in the Baie de la Seine by the Cotentin, and reflected across Channel on to this coast?

7. (1) At spring tides the range is considerable. (2) Perhaps one hundred yards at *spring* tides, not above three or four at neap.

8. Sand generally, overlying Blue Clay, which in places comes to the surface between high water and low water.

9. b. The shingle varies extremely in amount. Generally it lies in small detached heaps, but during east winds sometimes forms a small neap full. It is not real shingle, but gravel which has come from the cliffs. **c.** It distinctly travels east. **d.** Chiefly small angular (Plateau) gravel, but there is a certain number of large grey pebbles, well rounded, which also come out of the cliffs. [Out of pebble-beds, or layers, in parts of the Bagshot beds.—W. W.][1]

10. Till 1867 the shore from this side of Double Dykes to the Head consisted of two large shingle fulls; in that year (owing to the removal of the ironstone in the Head, which formed a natural groyne reaching out to the Beerpan rocks) the shingle began to travel round the Head and form the sand-spit at Christchurch.

12. There are no groynes, except under High Cliff Castle, beyond Christchurch. There there are three or four, made about five or six years ago by Lady Waterford to check the wear at what was then the mouth of the river. Their object was rather to turn the river out than to protect the coast from the sea.

13. From 1847 to 1865 the ironstone was removed out of the Head, and from between high and low water, which formerly formed a half-tide reef. [Not done now. —W. W.] **b.** For a small private company, who exported it to Staffordshire. Private individuals (Mr. Holloway of Christchurch).

[1] The notes signed 'W. W.' are by Mr. W. Whitaker.

14. a. All along, but particularly at High Cliff Castle, Double Dykes, and Flag Head. (1) High Cliff.—Cliffs high, and rotten from landsprings. Waste very rapid, but checked now. Bute House, built 1760 (? about a quarter of a mile out at sea), was in 1830 so near edge it was pulled down, and present house built some considerable distance inland, now about 200 yards from edge. Half of the kitchen garden gone in 1875; in 1865 it was intact, and there was a path between it and sea. As this is the garden of the *old* house, if an estate map could be seen showing the old house, one would get a fair idea of the rate of waste, which was due only to the sea till 1867. (2) Double Dykes.—A little monument has been moved inland three times in about thirty years. N.B.—This is the point where the waste is most rapid this side of Christchurch, and where the main current hits the shore. (3) In 1850 there was a coastguard station at Flag Head and a field in front. The whole of this is now in the sea, and the 'Head' projects less than the rest of the cliff.

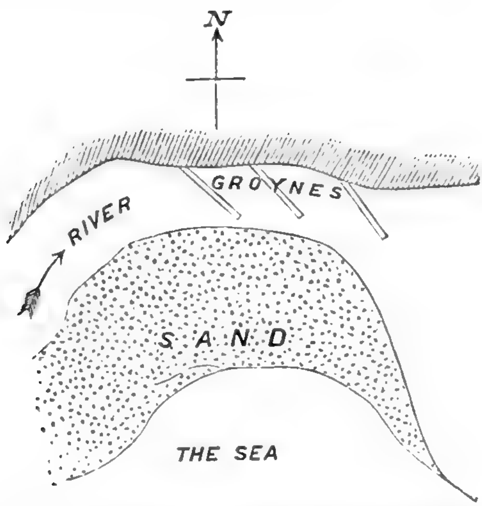

Fig. 7.—Sketch of Groynes, near Christchurch.

15. See **10.** **a.** No shingle is removed. **b.** There are no groynes but those at High Cliff.
16. None.
17. Yes, but they are small and only on the edge of the cliffs. Bent grass grows on them, but the fir woods are the chief check to their progress inland. [Refers probably to the blown sand along *top* of Bournemouth cliffs (see Geol. Map). —W. W.]
18. Papers by Redman and Coode, in the 'Proceedings of Inst. Civil Engineers.'

7. Sandown Bay.

By Lieut.-Colonel Garnier, R.E., Parkhurst, Isle of Wight.

1. The flat portion of Sandown Bay, between the cliffs at Shanklin and those at Yaverland.
2. a. Clay; blue slipper, covered with sand and shingle. Shanklin Cliffs, hard sand. Yaverland Cliffs, sand and blue slipper. (1) 120 feet. (2) 100 feet. (3) 0 feet; between Sandown and Yaverland.
3. North-east and south-west.
4. South-west.
5. a. South-west and south-east. **b.** North, because water is smooth in shore, and no undertow, which removes shingle as fast as it is deposited by rising tides. **c.** South-west.
6. Tide flows from south-west; ebbs in same direction.

7. (1) **a.** 10 feet. **b.** 8 feet. (2) **a.** 70 yards. **b.** 50 yards.

8. Clay; blue slipper with sand and shingle over.

9. Shingle. **a.** 20 yards mean; 50 yards greatest. **b.** Up to high-water mark. **c.** North-east. **d.** 5 inches by $3\frac{1}{2}$ inches. **e.** Continuous slope, except where affected by groynes, &c. With north wind there is a bank about 4 feet high formed at high-water mark, spring or neap tides.

10. Accumulating under Yaverland. A sea-wall was built thirty years ago from Sandown eastward, to prevent the sea washing away the coast road running along the flat portion of the coast, about half a mile in length. Before that there was an accumulation of shingle at the east end of Sandown which has since been swept more eastward.

11. It is stolen now and then from the above low portion of the coast.

12. **a.** Perpendicular to shore-line. **b.** From 60 to 250 feet. **c.** From 100 to 200 feet. **d.** (1) From 3 to 8 feet. (2) From 2 feet to 0, being sometimes covered with sand or shingle. **e.** Hitherto of wood; but last year (1883) two concrete groynes were built by Royal Engineers. **f.** The long groynes accumulate a greater mass of shingle, because they arrest the travelling of the shingle; the shorter groynes accumulate it chiefly at foot of sea wall. To preserve the latter from being exposed, and the blue slipper on which it is built from being washed away, numerous short groynes are necessary; but long groynes at intervals are required to arrest a large quantity of shingle.

13. Of late years all removal of shingle has been forbidden between tide-marks.

14. **a.** At Yaverland and Redcliff, about 100 feet in places in last thirty years, but a sea-wall has now been built at foot of cliff, opposite Yaverland. **b.** 100 feet to 150 feet; clay and sand mixed. **c.** No change observable for some years, probably because of the shingle now accumulating at foot of cliff. **d.** Originally the land between Brading Harbour and Sandown was covered by the sea. **e.** Probably (vide **c**).

15. The groynes east of Sandown to protect sea-wall do not appear to have prevented the accumulation of shingle at Yaverland.

16. No.

17. Yes, at St. Helens. **a.** Called 'Douvre.' **b.** 8 feet and 10 feet. **c.** At the mouth of the stream called the Yar, which runs into Brading Harbour. **d.** No. **e.** No. They are local drifts from the sands near Brading.

---

8. Brading Harbour, &c.

By RICHARD B. GRANTHAM, F.G.S., M.Inst.C.E.

1. I know the coast commencing at the north point of Culver Cliff, and proceeding to Foreland. From the eroded beds of the Chalk, the coast is covered with stones lying on the red and green Clay of the Bembridge Clay. The coast has been very much eroded all round, to the Yar and Bembridge Point, where there is Sand and gravel, and a ledge of rock at Nodes Point, on the other side of the Yar. I and my son are consulting engineers to the Brading Harbour Company; we have executed the reclamation and harbour works on the Yar.

2. There are no tide-marks or means of noting the erosion, and there are no cliffs for this distance. At the entrance of the River Yar there are the remains of an old church, from which northwards the cliffs begin to rise gradually to about 100 feet. They consist of pale-greenish and yellowish Marls and Clays, hardening into Sandstones (with *Melania excavata*), dipping from the eastward, and rocks appearing on the shore; the whole in the Bembridge series. Along a great part of these cliffs the proprietor built a wall at the foot to protect them from slipping, but the water in them forced out the strata, and parts of the wall have fallen, and have not been repaired as occasion required. But the wall has generally stopped the erosion, and would have done so entirely if timely attention had been paid to it.

3. The direction of the coast-line from the Culver, above described, is north-east to Foreland; thence to the Yar, north-west; from the Yar to the Priory Estate due north, and thence to Nettlestone Point, north by west, to Sea View.

4. South-west, and consequently the cliff is protected from that wind; but the tide runs and erodes the cliff at its base for some distance. The edge of the land is low, and shore strewn with rocks washed out of the soil. The sea rises nearly up to the level of sand up to Sea View.

5. The above wind causes the highest waves and erodes the shore, which on the south of the island is much exposed to the heavy seas of the British Channel. There is little or no shingle on this coast, except in patches.

6. Is round the south point of the island, along the coast to Chine Head, and along the coast past the Culver Cliff and Foreland, and thence into Spithead, and thence up and down Portsmouth Harbour, and into and out of the Solent.

7. (1) **a.** 14 feet at Bembridge Point; **b.** 10 feet 6 inches. (2) There is no general width, as the shore for the most part is rocky or covered with rocks. In a few places there are sand and gravel beaches.

8. Bare rock, shingle, sand, and mud.

9. a. As previously stated, there is very little shingle, and only in patches. The breadth of these varies very much, they being principally scattered stones. **e.** The beach is extremely irregular in its surface.

10. There appears no accumulation or diminution, owing to the absence of shingle. The chief erosion is by stones being washed out. The rock appears in patches.

12. There are no groynes in this distance, except at Bembridge Quay, where one was erected about two years ago. Sand has accumulated on the seaside alongside the landing-place, and is prevented from filling the bed of the dock, or place for vessels to lie, 150 feet in length. **e.** It is built of stone, which was dredged out of the river Yar, in the harbour, to deepen the channel. **f.** It stops the sand from getting into the berth of the steamer at the landing-place, and is raising the beach with shingle, opposite the Royal Spithead Hotel.

13. None that I could hear of. **d.** Reefs have certainly protected—both half and full reefs.

14. c. There were no means of remarking the rate of erosion. **d.** I did not hear of any maps which would show the amount of erosion in this case.

16. The only increase I know of is the reclamation of Brading Harbour, consisting of 600 acres, by embanking it from the sea and forming quays for shipping. The embankment forms a roadway from St. Helens to Bembridge, and was constructed to reclaim the land for agricultural occupation. Quays were erected on both sides of the harbour below the seven sluices by which the water is discharged from the River Yar at low water. The ships bring coals for the southern and eastern sides of the island, in connection with the Isle of Wight Railway.

17. There are no dunes, and there is no blown sand on the coast. The only sand-hills are those on the north of the mouth of the River Yar; in front of them is a sand-beach, with gravel interspersed over it. The sandhills extend from the Yar for about half a mile northwards to the Old Church. The hills vary from 10 feet to 20 feet in height, and are covered with marram grass. There are sand-banks on both sides of the mouth of Brading Harbour and River Yar, and there is no shingle; the sand is not blown, but remains always the same height, and does not seem to extend.

---

9. Bembridge, &c.

By Lieutenant NORRIS, R.E., Portsmouth.

1. Sea View, Isle of Wight, southwards to Bembridge and St. Helens, Isle of Wight. Much information was obtained from the chief boatswain of the Coastguard at Sea View.

2. Steep broken slopes, almost amounting to cliffs, intersected where streams run into the sea. **a.** Principally blue Marl—locally known as the 'blue slipper'—with beds of Limestone several feet in thickness, sloping about 5°. These strata are bent to a wavy section between the layers of blue Clay in places. Layers of red Sand and white Sand crop out occasionally. **b.** At Nettlestone Point, round Sea View: (1) 20 feet, (2) 7 feet, (3) 4 feet. From Horestone to Church Ruins: (1) 105 feet, (2) 50 feet, (3) 5 feet.

3. N.N.W. by N. to S.S.E. by S.

4. S.W. nine out of twelve months (off shore).

5. a. S.S E. to E.S.E. **b.** N.W. with a spring tide and swell deposits shingle in small quantities round Nettlestone Point, and round the fort at St. Helens. **c.** S.W. clears the shingle from Nettlestone Point, and replaces it with sand.

6. In shore at Nettlestone Point, tide runs $5\frac{1}{2}$ hours W. on flood at $3\frac{1}{2}$ knots; $6\frac{1}{2}$ hours E. on ebb at $2\frac{1}{2}$ knots. Off shore at Spithead, tide runs 5 hours W., 7 hours E.

7. (1) **a.** 18 feet. **b.** 11 feet. (2) At Nettlestone Point about 100 yards. Thence to Sea View Pier, about 150 yards. To end of sandbank outside Horestone Point rocks, about 250 yards. Horestone to Node's Point, about 200 yards. Node's Point to the Dovers, 300 yards to 500 yards. All at spring tides; half these distances at neap tides.

8. It consists of sand, limestone, or marl covered slightly with sand, gravel, or shingle, according to wind and tide; but between Sea View Pier and Horestone Point there are always 100 yards of clear sand. Opposite the Priory, and extending south of Node's Point, limestone beds appear on the level of the beach.

9. a. There is never any large quantity, except round St. Helens Fort. **b.** Accumulates near high-water mark, but varies with every tide. **c.** N.W. to S.E. **d.** Would pass through a 3-inch mesh. **e.** On Sand or mud shingle lies evenly and thinly; on rocky beach—Limestone beds—it fills the fissures.

10. Neither. In travelling S.E., a N.W. wind with a high spring tide to E. causes an eddy round Nettlestone Point, depositing shingle. It also is interrupted by St. Helens Fort. In S.E. gales, the backwash of the waves clears the coast of shingle.

11. Not diminishing (see **13.**)

12. Groynes are employed between Nettlestone Point and Sea View Pier, to protect the sand-beach from shingle, and to protect the sea-wall. Also north of Node's Point, 50 yards apart, rubble masonry at right angles to sea-wall, 5 feet thick at base, 5 feet high, and semicircular at top. **a.** Right angles. **b.** About 30 yards. **c.** About 30 yards. **d.** Present height, 3 to 4 feet above beach; present depth, wood about 5 to 7 feet, concrete 3 to 4 feet; apparent height varies with deposit left at each tide. **e.** A single row of halved 12-inch piles ($\frac{1}{2}$-round) with a longitudinal plank spiked on, or a straight wall of concrete 18 inches to 2 feet thick. **f.** Protect the sea-wall.

13. At Nettlestone Point only. **a.** Base of sea-wall at high-water mark. **b.** Building and roads. **c.** Private individuals. **d.** No; but the accumulated shingle at high-water mark protected the base of the sea-wall, now exposed.

14. a. From the Priory to Old Church ruins, principally round Node's Point. **b.** 50 to 105 feet at the top of inner slip. **c.** Average 7 feet in 12 months at present, but going locally about 20 feet at a time in a single slip, the contents of which, in S.E. gales, are carried off by the sea. The rate is increased by heavy rains and wet winters, as the slip is in the first place independent of the sea, which only removes the *débris*, which by its weight and the pressure of retained water forces out the sea-wall at its base. **e.** Yes, it is independent of the presence of shingle.

15. No. The course of the shingle lies outside the groynes, setting S.S.E. from Nettlestone Point.

16. None north of Brading Harbour, in which a company is reclaiming a large area by dredging and embankments.

17. Between Church Ruins and Ferry House on north side of entrance to Bembridge Harbour. **a.** At the Dovers (pronounced Duvvers). **b.** Mean 5 feet, some 15 feet, above high-water mark, ordinary spring tide. **c.** Occupying the north side of the entrance to Brading Harbour, opposite Bembridge, and the spit called St. Helens Sandbank. Brading Harbour forms the mouth of the River Yar. **d.** No. **e.** Yes; but as the ground is used for golf links, short grass has made a surface on the inside of the outer line of dunes, which prevents the heaps themselves from travelling. They form an embankment at high-water mark.

19. The serious loss of rich land at the top of the cliff is due primarily to the action of the Clay, or the 'blue slipper' (as is best seen at the undercliff of the Isle of Wight). This accumulates the rainfall, which presses against the sea-wall at the foot of the slopes. There is not more than one 3-inch weephole to 8 yards of wall, which is quite insufficient to relieve the pressure. The wall

is 7 feet high, 5 feet wide at beach, and 3 feet at top. Dovetail about 10 feet deep and of like section. North of Node's Point about 200 yards of this has been forced away, and is now being rebuilt as before in coursed rubble, stones being of no great size. The dovetail buttresses are too few, and placed near Node's Point, round which the wall has a semicircular trace, and has stood better than where it is straight, facing east. After rain, the fissures in the clay let the water through, and widen in the process, the mass supporting a breadth of 10 to 20 feet of the top surface gives way, carrying down trees, &c., and slips on to the second terrace of the slope, which in turn slips forward against the wall already supporting the water-pressure. This gives way generally at the beach level, just above the foundations. A S.E. gale then disintegrates the broken wall, and carries off the lowest portion of the slipped *débris*.

---

10. Pagham.

By RICHARD B. GRANTHAM, F.G.S., M.Inst.C.E.

1. Pagham. I was engaged in 1875–77 by the office of Woods and Forests to report upon the effect upon the property of the Crown of the reclamation of the harbour from the sea by a Company, who had erected a bank and sluices for the purpose. The following information refers to the shingle-beach outside the harbour, on the sea-front.

2. The coast is generally low flat land, but at one part a large body of shingle has been for several years cast up by the south-west wind, and tides set round the point of Selsea Bill, where there is still water, causing a deposit of shingle. The shingle which has been brought there, is about half a mile wide and three miles long at low water. The harbour consists of 750 acres.

3. The direction of the coast-line is north-west up to Selsea Bill Point. Thence for 3 miles it runs north by east to the end of the shingle; in coming from the west the current passes Wittering and Earnly, and moves the shingle in a south-easterly direction.

4. South-west.

5. The south-west, which, as before stated, piles up the shingle, and moves it on along the coast towards Bognor.

6. After tides pass Selsea Bill, the current sets along the coast eastwards, and in the Channel the set is from west to east.

7. (1) Springs range up to $16\frac{1}{2}$ feet, and neaps to $12\frac{1}{2}$ feet. (2) About 880 yards.

8. Shingle opposite Pagham Harbour.

9. c. Opposite Pagham Harbour, east of north. **d.** They vary from 2 inches to 6 inches and 8 inches in diameter. **e.** The slope of the shingle is mostly uniform, but altered by heavy seas and strong currents. There are no tide-marks.

10. The top line of the shingle bank is neither raised nor diminished except in great storms, when the sea front is affected one way or another by storms or strong currents.

12. There are no groynes in any part of the coast within the limits of this report.

13. There is no material taken from the foreshore that I could discover or hear of.

14. The shingle bank entirely prevents any of the coast from being worn away by the sea for the whole length to which this report refers. **d.** I could find none, and it was not in the memory of any person when the bank did not exist.

16. Under this head it will be well to describe the harbour and works by which the land has been reclaimed. Upon my first visit, as stated in the beginning of this paper, to this harbour in 1875, for the Office of Woods and Forests, some large wooden sluices had been erected at the end of the stream on the land, from which the water, when the tide was out, was discharged into the channel of the former course, which I reported upon unfavourably on the next occasion, in 1877; and subsequently a new plan was adopted: a tunnel was made under the shingle bank to low water on the sea front, in which sluices were placed, and they have kept the land reclaimed safer. The water now passes directly seawards, at right angles with the coast.

18. I did not meet with any papers or maps except those of the Office of Woods and Forests, which were returned with an Act of Parliament. There was an arbitration held, which also condemned the wooden sluices which I referred to, and the tunnel and sluices were adopted.

19. This is but a small case, but is extremely important to those locally concerned; and shows also the cause of so large an accumulation in that part of the coast. I know of no other like it.

---

11. Worthing to Lancing.

By RICHARD B. GRANTHAM, F.G.S., M.Inst.C.E., Inspector under the Land Commissioners.

1. Part of the south coast, between Worthing and Shops Dam, Lancing.

2. The coast consists of a wide shingle beach.

3. The coast-line curves inwards towards the north-east between the points above referred to.

4. The prevailing wind is from the south-west.

5. South-west.

6. The mean set of the tides is E. by N. along the line of coast, but in Mid Channel it is east and west.

7. The range of the tides is:—Springs, 14 feet; neaps, 10 feet.

9. a. The mean breadth is 40 feet. **c.** Eastwards. **d.** The maximum size of the pebbles is about 6 inches diameter. **e.** The front of the beach consists of two slopes. That from low water upwards is nearly flat, and towards the upper or crown rises steep from 2 to 1 and 3 to 1.

10. The shingle is accumulating, as will be described when referring to groynes.

11. It is not diminishing in height or breadth.

12. Groynes were commenced in 1873, and have to the present time been the means of arresting and accumulating shingle. They differ from the ordinary groynes, being of great length from the top of the shingle beach to beyond low water, probably 200 feet in length, and were placed 500 feet apart, forming an angle varying from 80 deg. to 63 deg., with the coast-line. They are fifteen in number, and are built of fir piles and planking, and supported by land ties. In places where the shore-line was not quite straight with the main line the beach was hollowed out, and intermediate groynes were placed which stopped the beach; these were of less length and height than the main groynes.

13. It is not removed artificially, as it is private property, from any part of the front line of the beach, but probably is taken for repair of roads at the back of the bank. **d.** There were no half-tide reefs formed anywhere in the distance above referred to as natural breakwaters.

14. The coast-line is not worn back by the sea, as the beach, as now protected by groynes, completely prevents such action, except just east of Worthing, where there was a shingle bank, and groynes were erected in a bend of the land, but the bank was swept away and the piles of the groynes were taken up, and near that spot the public road was cut through, and the sea flooded the land inside. The road led from Worthing to Lancing about three years since, but has not been reinstated. The piling and groynes at Worthing town are in a very bad state, and the shore requires quite a different kind of protection.

15. Entirely caused by the power of the sea near Worthing, by the abstraction of shingle.

---

12. Lancing to Shoreham.

By RICHARD B. GRANTHAM, F.G.S., M.Inst.C.E.

1. I have become acquainted with the coast from near the Coastguard Station, which is on the beach opposite Shoreham, in Sussex, by being employed by the Land Commissioners to report on the erection of sea-groynes from there to Shops Dam, near Lancing, on the beach westwards, of which there are fifteen.

2. From the place described above to Lancing, as well as some distance westwards (for about $3\frac{1}{2}$ miles in all), the coast is formed of a shingle-beach of great width, but there are no cliffs.
3. It is north of east, curving towards the north as it approaches Brighton.
4. South-west.
5. From the west. It moves the beach eastwards, and has piled it up about 4 to 5 feet, and made it broader by accumulating it on the sea side. This refers to two-thirds of its length between the points stated above from the coastguard station to Shops Dam; and at the back of this length, an excavation was made by the proprietor of the adjoining land, from which a high bank was raised some years ago, adjoining the high road, to prevent the sea from overflowing; and a few years since he had these groynes erected, and I was appointed to inspect their construction. The front of Worthing has been thickly groyned.
7. (1) **a.** 14 feet 2 inches. **b.** 10 feet 1 inch. (2) About 90 yards.
8. Of shingle.
9. **c.** From west to east. **d.** Six inches diameter. **e.** The shingle forms a continuous slope from the low-water line to the top of the bank, but it is irregular, owing to the tide raising a bank along the face of the slopes, and washing out the shingle, causing flat places.
10. Since the groynes were constructed the shingle has accumulated. The sea has not flowed over the bank of shingle since the groynes were erected. The sixteen piles of groynes have cost nothing since they were erected in 1877–78.
11. The top of the bank has risen, and the shingle has increased in thickness on the sea-front.
12. **b.** About 275 feet, extending from low to high water. **c. d.** At their upper ends they are 500 feet apart, and are parallel to each other. At A on plan, three intermediate groynes were put in between groynes 8, 9, and 10, each 160 feet in length, and the shingle has completely covered them where the beach before was laid bare at that particular part. The groynes were built in 1877–78. They are built generally at an angle of 70° to 75° to the shore, or high-water line pointing south-east. **e.** Memel timber square piles driven into the beach, planked on the weather or west side, and stayed into the beach by land ties, fastened by piles at the ends. **f.** They are the means of stopping the beach and causing it to accumulate on the west side, raising it from 4 feet to 7 feet on the east side of the groynes, and thereby preventing the sea from eroding the coast.
13. No.
14. **b.** There are no cliffs except between Worthing and Lancing, where the land is higher than the public road. At one point near Worthing the road was washed away and some of the land at the back of it some years since. At the town of Worthing, the sea-front is protected by groynes which are very numerous, and sufficiently support the road; but this is beyond the district I personally know.
16. No; there is not any.
17. No; there are no 'dunes.'
18. I have inquired for such papers, but there are none. The only paper that has any account of these groynes and sea-shore is the 'Brighton Gazette' of February 26, 1885.

---

13. Littlehampton to Brighton.

By W. E. C. NOURSE, F.R.C.S., Bouverie House, Mount Radford, Exeter.

1. The coast of Sussex from Littlehampton to Brighton, since 1832.
2. The land is bounded by a shingle-beach the whole distance.
5. Winds from the south-west, or thereabouts, have constantly made the waves *pile up* or *remove* shingle. *Piling up* has mostly been caused by moderate gales. *Removal or erosion* by storms. Besides which, the constant action of these winds on the waves has occasioned a constant travelling of shingle from west to east.
6. The sum of the ebb and flow is a set to the eastward, in which direction things always drift.

7. (2) Spring—at Worthing and Littlehampton said to be a mile, and appears quite that distance. Neap—at Worthing and Littlehampton, not a quarter the distance.

8. Sand, with occasional patches of small chalk rocks. The sand, off the east end of Worthing, rests on Blue Clay, found at a depth of less than 2 feet from the surface.

9. As already stated (**2** and **8**) the shingle is confined to the beach. The beach varies in form from time to time. After violent south-west storms it appears stripped away in many places, where not retained by groynes. After moderate gales it is piled up, not only by the sides of groynes, but also in longitudinal ridges at or near the top of the beach or half-way down, the shape, length, and duration of the ridges being constantly varied. At some seasons tons of seaweed cover the beach after a gale. Of the high shingle-beach existing in Queen Elizabeth's time, with a backwater to the landward of it, the only portion which remains is about Lower Lancing, and perhaps a little about Hove.

10. The shingle, which, as stated, is confined to the beach, has for some years past appeared to me slowly diminishing, but I do not know at what rate.

11. To artificial abstraction mainly, but not perhaps wholly.

12. Groynes are employed at various points, mostly at right angles to the shore. Groynes on this coast are of three sizes, according to their usual dimensions: small, which may be left out of the account; middling, of moderate height and length; and large, of greater height and length. Also, in some places, three or four are crowded together, elsewhere they are wider apart; again, considerable lengths of shore have no groynes at all. **e.** Most of them wood, one or two concrete. **f.** In all the years I have known the coast, the most erosion, the greatest encroachments of the sea, have been where shingle was deficient—that is, where there were no groynes, or insufficient ones. Erosions of limited size have also been generally observed to the eastward of *large* groynes, also to the eastward of spots where three or four groynes were crowded together; such erosions being noticed as hollows in the shore and more or less considerable notches in the land, while shingle was largely piled up on the west sides of the groynes. Erosions have always been noticed to be at a mimimum, or altogether arrested, where groynes of *moderate* height and length (according to their usual sizes), and in good repair, stood at (say) 30 to 100 yards apart, or at such distances as to maintain an *equal distribution of shingle* along the whole shore line, without piling it up at any particular part.

13. a. b. *Shingle* is taken from the beach about high-water mark. *Sand* is taken from various parts of the flat covered by the tide. The taking of these things has been usual as far back as I knew that coast, before 1830. *Shingle* has constantly been used to repair the roads within a mile or two of the shore; fine shingle has been taken for garden walks; large boulders to build with. Most of the walls within two miles of the sea have been built with boulders from the beach. *Sand* is mostly taken for building purposes. *The sands* at low water between Littlehampton and Lower Lancing used (1832 to 1842) to be noted for their extent, evenness, and firmness, so that they were favourite places for riding and driving. Races were then annually held on the sands both at Worthing and Littlehampton. Of late years (1850 to 1870) they have appeared to me not so dry and even as they used to be. At Brighton the sands are clearly at a lower level than formerly. The rounded chalk rock sticking up out of the sand eastward of the Chain Pier, near the first pair of towers from the land, in 1834 only showed a small portion of its rounded top. It is now visible 18 or 20 inches lower down, showing that the level of the sands is now so much lower than it was in 1834. **d.** Not to my knowledge.

14. The whole coast from Littlehampton to Lower Lancing has been in a constant state of erosion ever since 1832, some parts more than others. The worst part is at Kingston, near Rustington. Here the shore has been continually washed away for many years; at what rate I do not know. I have seen but little shingle here, and the sea washes up against the low clay margin of the flat land. I have always heard it reported that a large part of Kingston parish has been washed away, and that foundation-stones of the parish church can still be seen at extreme low-water mark. Dixon ('Geology of Sussex,' p. 34)

refers to the waste of land by the sea opposite the parishes of Rustington and Preston, mentions remains of trees on the shore, and speaks of Ruston Park, with large trees, standing [in 1704 [1]] on what is now the sea. He also (p. 35) mentions a tradition that [in 1704 [1]] the land at Tarring extended much further seaward. At Worthing like traditions prevail. I was told in 1832 that old men remembered the land being out as far as the grass-banks. Opposite College House School, Worthing, the sea in 1832 was washing away the beach, and laying bare the foundation of the playground wall. A moderate-sized groyne was put down, which made beach accumulate, and the encroachment stopped. I saw four similar groynes put down that same year opposite Mr. Elwes's large house; these also produced an even shingle beach which stopped encroachment. But just east of College House playground was an extra large groyne, with a great pile of shingle west of it and a large hollow eastward. Close to this was a coastguard house. About fourteen years after, I found that this house and the ground it stood on were entirely gone. Dixon (p. 37) says 70 feet of land were destroyed here in twelve months. Many years ago I saw the remains of the coast road, half washed away, that ran from Worthing past Heene towards Goring. The coast road from Worthing to Lower Lancing was then perfect and in regular use. I believe it is now dilapidated by the sea. The sea-front of Worthing, being cared for and protected, has never been changed within my recollection. Dixon (p. 37) says 'the sea formerly gained much on the shore.' At Littlehampton, the Baths, a building which stood on the beach in 1835, has been entirely destroyed.

---

14. Newhaven and Seaford.

By A. E. CAREY, Resident Engineer, Newhaven Harbour Works, Sussex.

1. More especially the coast from Old Nore, Newhaven, Sussex, to Seaford Head.

2. The coast consists of two Chalk headlands, respectively 180 and 250 feet above sea-level, with an alluvial valley between, forming roughly the segment of circle to sketch. One mile from the eastern headland a low range of chalk hills about 60 feet high comes down to the sea front.

4. W. to S.S.W.

5. a. W.S.W. **b.** S. to S.S.E. **c.** N.W. to W.N.W.

6. The flood tide in the Channel striking Seaford Head causes a false or counter tide in Seaford Bay.

7. (1) **a.** 20 feet. **b.** 16 feet 6 inches. (2) **a.** About an average of 200 feet. **b.** About an average of 120 feet.

8. Shingle and sand, covering a partly artificial bank of clay and mud.

9. a. Depth varies so greatly that it is difficult to state with any accuracy. The greatest depth would be about 10 feet, mean depth perhaps 3 feet. **b.** Bank above mean high water varies little. Remainder of bank constantly varying. **c.** W. to E. **d.** Say 5 or 6 inches one way. **e.** Except above mean high water, the shingle forms generally a tolerably uniform continuous slope. After a succession of southerly winds, fulls are sometimes formed, but these are very variable.

10. The shingle is slowly diminishing, none now coming from the west side of the harbour.

11. To a small extent only from artificial abstraction.

12. a. About S.S.W. **b.** To low-water mark. **c.** About 150 yards. **d.** (1) About 8 feet out of ground. (2) About 4 feet, very variable. (3) About 1 foot, very variable. **e.** Timber piling planked. **f.** Their influence has been to arrest and maintain the existing banks of shingle. The whole of the system of groyning has been carried out by the Newhaven Harbour Co., who have recently constructed a sea wall about 20 feet in rear of the top of the foreshore bank, from the east pier to about $1\frac{3}{4}$ miles east of this. These combined works will render the foreshore secure, probably for many years.

13. a. Above high-water line principally. **b.** For the purposes of sea-walling, breakwater construction, &c. **c.** Under the Act of the Newhaven Harbour Co. **d.** No.

[1] These dates, 1704, are gained by calculation, not given by Dixon.

14. Yes. **a.** Especially in recent years opposite Blatchington Battery, which has for this reason been abandoned. **b.** Chalk cliffs about 40 or 50 feet high. **d.** Numerous maps exist of this strip of coast-line. A highway road between Blatchington Battery and the sea was washed away about twelve years ago. **e.** No; at Blatchington Battery the shingle is plentiful, and moves freely. A small groyne would probably arrest erosion at this point.
15. No; I think not.
16. Frequent floods, sometimes covering some hundreds of acres of land, occurred previous to the works named being carried out. On the west side of the harbour about seven acres of foreshore have been enclosed by a wall and reclaimed.
17. No dunes of sand exist here.
18. Numerous reports and maps of the sea-front exist, but these being out of print are difficult to obtain. Up to the time of the erection of a large groyne west of Newhaven Harbour in 1847–48 the movement of shingle was unchecked, and the loss at the east end of the bay was replaced by shingle travelling from the west. This groyne appears to have permanently checked the movement of the shingle, and erosion has taken place principally at the centre of the arc formed by Seaford Bay. The object of the present works is to retain what shingle remains, and to arrest its movement. A concrete sea-wall has been erected opposite the town of Seaford; and if this wall and that of the Harbour Co. were united (the distance being about 1,400 yards) Seaford Bay would be safe for many years. West of Newhaven Breakwater large deposits of shingle are accumulating.

---

15. Beachy Head to Hastings.

By Colonel E. C. Sim, R.E., Royal Engineer Office, Brighton.

1. From Beachy Head to Hastings.
2. Mostly cliff, with the exception of Pevensey Bay, chalk, and sandstone. The greatest height is 512 feet—Beachy Head.
3. South-east.
4. South-west.
5. **a.** S.S.W. **b.** S.S.W. **c.** S.S.W.
6. To the eastward.
7. (1) **a.** 21 feet 9 inches. **b.** 15 feet. (2) **a.** 150 yards on an average. **b.** 120 yards on an average.
8. Shingle and sand.
9. **a.** 20 yards to 50 yards generally, but in Pevensey Bay the shingle is nearly a mile wide. **c.** South-east. **d.** 6 inches by 3 inches. **e.** Continuous slope.
10. Diminishing slowly.
11. Partly artificial.
12. **a.** South-west. **b.** From 80 feet to 250 feet. **c.** 100 yards at Eastbourne. **d.** (1) 12 feet to 15 feet. (2) 12 feet. (3) Full. They vary in length and distance apart at different places along the coast. **e.** Oak and beech. **f.** Prevent the scour of the sea, and to a certain extent retain the shingle.
13. **a.** Half-tide. **b.** Building and concrete work. **c.** Local builders. Corporation of Eastbourne, and Local Board at Bexhill. Newhaven Harbour Co. **d.** Slightly, near Beachy Head.
14. **a.** Generally. **b.** Sandstone and chalk. Height varies. **c.** It varies, but during the last twelve months about 10 feet at Bulverhythe, near Hastings. **d.** There are some old maps. **e.** No.
15. This cannot be stated positively. **a.** Probably to some small extent. **b.** Groynes appear to save one part of the foreshore to a certain extent at the expense of another. The breakwater at Newhaven Harbour appears to prevent the accumulation of shingle between it and Beachy Head.
16. No. The inroads of the sea are checked at Hastings, Bexhill, Eastbourne, Newhaven, Brighton, Worthing, &c., by sea walls, which there is a general tendency to extend.
17. No.
19. Two Memoranda by Colonel E. C. Sim, R.E., are forwarded herewith. [Printed on pp. 410, 412.]

16. St. Leonards and Hastings.

By Richard B. Grantham, F.G.S., M.Inst.C.E.

1. St. Leonards and Hastings, Sussex. I have examined the coast from the east end of Hastings to the west boundary of St. Leonards, as shown on the accompanying map on the Ordnance scale of 6 inches to a mile.

2. Commencing at Ecclesbourne Glen, the cliffs of the Wealden formation on both sides of the glen attain a great height, and from the east side continue westwards to the town of Hastings, generally about 200 feet high. The shore is covered by the rocks which have from time to time slipped from the cliff, and form beach varying from 20 to 70 feet wide. The erosion is caused by water behind the cracks and clefts in the face of the rocks forcing out the stone during frost, this being the chief cause. The height of the cliffs is from 80 to 200 feet above Ordnance datum. There is a large groyne of stone at the Sewage Works, at which the stone beach ceases and the shingle beach begins; 500 yards from there the buildings commence, and a quay wall at the Stade, opposite Market House, continues for a little more than two miles westward. This wall retains the roads in front of the two towns for that distance, and against it the shingle-beach rests. (See the 6-inch Ordnance Map.)

3. The direction of the coast-line is from west to east by north.

4. South-west.

5. a. South-west wind and south wind as the direct wind on to the coast of Hastings and St. Leonards. **c.** From the westward.

6. From west to east, which is shown by the accumulation on the west side of the groynes.

7. a. The range is 24 feet. **b.** The range is $17\frac{1}{2}$ feet.

8. Shingle with sand.

9. a. At Ecclesbourne the shingle is about 150 feet wide at high water, and at the Sewage Works about 200 feet, and continues pretty uniformly that width owing to the line of the retaining wall. **c.** From the westward. **d.** About 5 or 6 inches diameter. **e.** There is not a continuous slope, as it is in steps at the line where the last and strongest force of the tides left the shingle-bank.

10. I did not hear that there was any permanent accumulating or diminishing of the shingle except at the groynes, where it accumulates on the west sides of them, and against the face of the retaining wall, where in places as well as at the groynes the height was as much as 10 feet of accumulation.

11. I did not see or hear of any diminution at any part of this length, and I should suppose that as the Wealden rock forms the bed upon which the shingle rested, there would be neither diminution nor abstraction. For the whole of this distance nearly the rock appears, and slopes towards the sea and there meets the sand.

12. The groynes are very numerous, and in late years many more seem to have been placed all along this length except at the western end. [I have placed on the 6-inch Ordnance Map all the additional groynes, as will be seen by the lines in pink colour.] They have all been built of oak-timber piles and deal planks, and are tied into the beach by trees of oak. They arrest the shingle, which accumulates on the west sides; in some places at their upper ends the beach is as much as from 6 feet to 10 feet higher than on the east sides. They are generally placed at right angles to the front wall, and in some cases are upwards of 200 feet long, but generally 120 to 150 feet long. The distances apart vary very much, but the tops of them are level with one another in nearly all cases. The influence that they have exerted is to protect the wall or any building against which they abut.

13. I could not discover or learn from any person that any materials were removed artificially or otherwise, but I believe that a strict watch is kept in order to prevent any removal. **d.** I heard of none and saw none.

14. No. **b.** The cliffs, except east of the town, do not wear away, as they are protected by houses or walls.

16. There has been no increase of land by the accumulation of shingle.

17. There are no 'dunes' in this district.

18. I tried to get maps, sketches, or pictures, but I could not find any of value for the purposes of this inquiry.

17. Dover.

By E. R. N. Druce, M.Inst.C.E., Engineer to the Government Pier, Dover.

1. The part in the neighbourhood of Dover (South-East coast).
2. Cliffs. **a.** Chalk. **b.** Shakespeare Cliff is, I believe, between 350 and 400 feet; average is 200 feet.
3. East and west.
4. South-west.
5. **a.** **b.** **c.** South-west.
6. Up and down Channel, east and west.
7. (1) **a.** Nineteen feet. **b.** Eight feet six inches.
8. Shingle and sand generally, but there is a boundary jetty at the east end of the Dover Bay which stops the shingle. To the eastward of this jetty the chalk rock is bare.
9. **a.** **b.** In Dover Bay the general width is 250 feet, about half of which is *above* and half *below* high-water mark. **c.** Its tendency to travel is *with* the prevailing wind, that governing the waves. **d.** About 2 inches maximum dimension with a tendency to decrease.
10. Diminishing all along the coast from Dungeness to Deal, except at such intermediate points where artificial means have been taken to arrest its progress.
11. Only partly. There is a loss by friction on travelling, but the supply from the westward no longer continues.
12. **a.** Generally at right angles or perpendicular to the shore-line. **b.** Various. There is no system, whether with reference to structure or height or length; some are 150 feet long. **c.** Sixty to seventy yards, where there are any. To the west of Dover the greater part has disappeared altogether. **d.** (2) The top line of the latest built, which are at the east end of the Bay, runs from five feet above high water to about two feet above low water. In Dover Bay the upper portion of the groynes at this date are buried in the shingle, and there is no variation in the levels of the shingle on the east and west sides. They seem to have been constructed with reference to their own security, and have no apparent effect on the shingle. **e.** The best are made of double railway irons with three or four-inch planking. **f.** Both to the west and east of Dover Harbour there are large boundary groynes of stone which retain to some extent the shingle within the extreme limits of the authority which has the control of them. There are, then, the various intermediate timber and railway iron groynes which more or less, according to their height and length, arrest the movement of the shingle.
13. **a.** Above high water. **c.** Principally local authorities. **d.** There are no tidal reefs.
14. Yes. **a.** Both to the east and west of Dover. At Shakespeare's Cliff to the west, where the cliff is at the maximum height (between 350 and 400 feet). The cliffs are also falling to the eastward of Dover, where they are from 200 to 250 feet in height. This is the result of their being undermined by the sea. **c.** It is at no particular rate, but falls of cliff at the points above named have taken place at intervals for some years past from the cause above stated, and since they have lost the protection of the shingle at their base. **d.** I think none. **e.** Yes.
15. It is due partly to the supply of shingle having been arrested at Folkestone, which is to windward of Dover. At the same time the supply to Folkestone has of late years greatly decreased in common with all the shore to the east of Dungeness Point. See Sir J. Coode, Report referred to in **18**.
16. No.
17. No.
18. Dover Pier.—Return to Order of the House of Commons, March 13, 1873, for copy of 'Correspondence relative to the Causes of the Wasting of the Shore to the Eastward of the Government Pier at Dover.' This contains Sir J. Coode's Report on the subject, dated July 3, 1873.
19. There is a large increase in the area of shingle to the westward of Dungeness. All the shore, speaking generally, to the eastward of Dungeness as far as Deal is now suffering from the supply being stopped. The groynes above referred

to may prevent to some extent the waste which results from friction, but unless the authority in each district provides boundary jetties with intermediate groynes, to 'fix,' as far as possible, the shingle, the whole of this part of the coast will, in my opinion, suffer from the want of the natural protection which the shingle has hitherto supplied. The cliffs are now being undermined in places, and must eventually fall.

---

18. Deal.

By Major A. C. HEPPER, R.E., Royal Engineer Office, Dover.

1. None, but I have made inquiries relative to War Department property at and near Deal, where the coast-line is, and has been, undergoing change.
2. Shingly beach at Walmer, Deal, and Sandown Castles, and No. 2 Battery; cliffs at Pegwell Bay Battery, Ramsgate, and Broadstairs. **a.** Chalk and flint. **b.** About 70 feet; 65 feet; 60 feet.
3. North and south.
4. South-west.
5. **a.** North. **b.** South-west. **c.** South-west.
6. North-north-east and south-south-west.
7. (1) **a.** From 18 to 20 feet, according to wind. **b.** From 12 to 15 feet, according to wind. (2) About 40 yards at Walmer, increasing to about 280 yards at No. 2 Battery.
8. Shingle, sand, and patches of rock.
9. **a.** Greatest about 450 feet; mean about 200 feet. **b.** Heaped up towards high-water mark; sand below half-tide. **c.** North. **d.** Size of an egg, but occasionally much larger. **e.** No, it is heaped up and changes with every gale.
10. At Walmer Castle accumulating; at Deal Castle variable, now accumulating; at Sandown Castle diminishing; at No. 2 Battery accumulating.

Place	From	To	Increase. Feet	Decrease. Feet

" "	1872	1884	—	5
No. 2 Battery	1859	1884	140	—

11. No.
12. Groynes not employed.
13. Not so removed.
14. Yes, the cliffs are liable to landslips from action of sea at base. **a.** Pegwell Bay, Ramsgate, and Broadstairs. **b.** Chalk and flints; height about 65 feet. **c.** Not known. At Broadstairs one landslip, causing a loss of 30 feet, has occurred since 1870. At Ramsgate a slip in 1875 set back edge of cliff about 5 feet. **d.** Ordnance and other maps in Royal Engineers' Office and Report of Committee on Coast Defences (confidential). **e.** No.
15. No.
16. No.
17. Yes, between Deal and Pegwell Bay. **a.** Sandhills. **b.** Mean about 10 feet; greatest about 15 feet. **c.** They are situated in rear of shingly beach of Deal Roads, and bordering the mouth of the River Stour. **d.** No. **e.** Not blown, being old and covered with vegetation.
18. See **14**, **d.**

19. Sheerness.

By Colonel LE MESURIER, R.E., Sheerness.

1. Sheerness, Isle of Sheppey.
2. Foreshore, about half-tide, of London Clay. Formerly salt marsh, now protected by clay, sea-wall paved with Kentish rubble rag, grouted with Portland cement, shingle at foot of wall. **a.** Cliffs of clay and loam from Warden Point to Scrapsgate Minster **b.** (1) 150 feet; (2) 100 feet; (3) 15 feet.
3. East and west.
4. East and north-east.
5. a. East. **b.** West and north-west. **c.** East.
6. From the north-east.
7. (1) **a.** 17·6; **b.** 12·6. (2) Opposite Sheerness, about 1,320 yards.
8. Mud and shingle.
9. a. About 70 feet and 120 feet. **b.** Between high and half-tide marks. **c.** East to west. **d.** About 7″ × 4″ = 5 lbs. **e.** One continued slope.
10. In some places one tide might take it all away if not retained by groynes. In others it is accumulating; owing to the groynes it is generally accumulating.
11. Diminution is due partly to artificial abstraction, partly to want of groynes.
12. a. Generally in a north-east direction. The west-direction groynes now run out at right angles to the sea-wall for about 50 feet, and thence towards the north-east. **b.** From 50 to 150 feet. The principal groynes are being lengthened to 200 feet; at salient portions of the coast the minimum distance is necessary, at re-entering portions the maximum is sufficient. **c.** From 50 to 300 feet. **d.** 1 foot 10 inches above the surface, and 1 foot 10 inches below—i.e. of four 11-inch planks. As the shingle accumulates to windward, planks are fixed one at a time. If the groynes are put near enough there need not be a greater difference of level than 2 feet, except on extraordinary occasions. Sometimes there is scarcely any difference. **e.** Oak-framed uprights, 11′ × 11″, sills bedded in concrete 8 feet apart, 3-inch fir planks bolted to these uprights. **f.** They catch and retain the shingle, forming an artificial beach or half-tide reefs, and thus protect the toe or foot of the sea-wall.
13. a. Near mean high-water mark. **b.** For concrete work and building requirements, footpaths, &c., by local builders and the War Department and Admiralty contractors. **c.** The Lord of the Manor of Marine Town, sea frontage, and of the land adjoining the boundary of Sheerness and Minster, east of the Co-operative Coal Pier. **d.** In some parts of the coast such half-tide reefs exist, and do so act. In other parts they have been removed, but whether by the increased force of the tide, owing to the removal of the cliff to the eastward, or by artificial abstraction appears a question.
14. Yes. **a.** The entire length of the island from Sheppey-Landsend, Warden Point, to Garrison Point Fort. **b.** Cliffs of loam and clay about 100 feet high from Warden Point to near Scrapsgate Minster, thence to Garrison Point. Clay and mud foreshore with more or less beach or shingle. **c.** No record in Royal Engineers' office. The parish of Warden has lost upwards of 220 acres within 220 years. **d.** It is understood that the Mayor or Corporation of Queenborough possesses a map of Sheppey dating from the reign of Elizabeth. **e.** Nearly so; the loss is greatest at the north-east part of the island, called Warden Point. Here the coast is quite bare of shingle.
15. No.
16. There is no increase whatever now. The area covered by shingle is becoming less every year. **a.** Nil. **b.** Much of the lowlands or marshes of Sheppey have been regained from the sea within the past 300 years.
17. No.
18. The earliest map of the coast-line adjoining Sheerness that we have in the Royal Engineers' office goes back only 150 years—it does not extend beyond a mile to the east of Garrison Point.

20. Chatham and Sheerness.

By J. CHISHOLM GOODEN, 33 Tavistock Square, London.

1. Have known the estuary of the Medway, between Chatham and Sheerness, and reported on it to the hydrographer of the Admiralty, Sir F. Beaufort, who ordered its resurvey by Captain Bullock, R.N. This resurvey confirmed my conclusion that a frightful waste of land existed there by erosion.

2. Alluvial soil.

7. (1) Chatham Dock. In 1840, Captain Bullock, R.N. **a.** 17 feet 3 inches. **b.** 10 feet 6 inches. In 1868, resurvey by Commander Calver. **a.** 18 feet. **b.** 14 feet 6 inches.

14. Medway estuary. Captain Bullock, R.N., reported to me May 28, 1880: **a.** Waste at Ockam Ness, 157 feet in fourteen years. Personally stated to me that the waste at Sharpness on the opposite bank of this river was 11 feet per annum during the same interval. Bishop's Marsh, 5 or 6 feet on all sides, and therefore the double. Hoo Marshes and St. Mary's Marsh, 3 or 4 feet. Upper Marshes, 2 or 3 feet. All this waste must have been intensified and increased greatly by the greater action of the waves derivable from greater water surface and the greater power of wind on the water. **d.** There are no data present to illustrate this; Admiralty appear to have stereotyped the configuration of the land here. There is an early map in the British Museum, *circa* Queen Elizabeth. There is Steele's map of 1802. Some of the soundings there were repeated by people I questioned, before Captain Bullock's second survey. **e.** There was scarcely any hard ground in my time, except in Upnor Reach. Some was said to be in existence in Wollopstone ooze, but I failed to find it by experiment of a disagreeable character. The creeks and inlets show remarkable shoalings.

15. Honestly think and say No, unless tidal oozes are land.

18. There was a correspondence on Rochester Bridge and the River Medway in 1812, and a blue book ensued from it, with observations by Rennie, C.E. The report of the City Corporation Commission, 1853, deals with evidence from Captain Bullock, R.N. I have written in the 'Times,' 'Athenæum,' and 'Household Words' on this matter.

19. My belief is, from the excessive waste of land, long continued, and necessarily increased, that the oozes must be rising; and there was evidence, after Captain Bullock's second report, that at Bishop's Spit the ooze had spread at the foot. My impression is that here, by natural action, we are slowly realising what the artificial works of the abbots of St. Augustine's and the Great Church of Canterbury did towards the loss of Sandwich Haven. They 'inned' the oozes and converted them to useful purposes; we do not; but we have considerable national properties at Chatham and Sheerness. We have the most imperfect data as to oozes; the charts do not give the depths thereon.

Chronological List of Works on the Coast-Changes and Shore-Deposits of England and Wales.

By W. WHITAKER, B.A., F.G.S., Assoc.Inst.C.E.

Having made many lists of geological works on various parts of England, from a topographical point of view, it occurred to me, some time ago, that there might be some advantage in having such lists arranged by subjects. The following is a first attempt in this line, and it may perhaps be of service to the Committee, and to those local observers working with it.

It is confined to the subject-matter of the Committee's inquiry, namely, changes within the historic period; and therefore, whilst it includes the titles of papers that refer to these recent changes and to the beds which are formed along our shores, including the so-called Sub-

merged Forests that generally occur beneath the beach where a stream flows into the sea, it does not include papers that merely give an account of cliff-sections or of raised beaches.

This list does not pretend to perfection, and notice of omissions will be thankfully received, so that any such may be included in a supplementary list, in some future Report. Of course such sheets of the Geological Survey Map as show sea-coast, give information on shore-deposits, but it hardly seems needful to mention each separately.

I have to thank Mr. Topley for many of the 431 entries now made.

Report of the Committee, consisting of Professor RAY LANKESTER, Mr. P. L. SCLATER, Professor M. FOSTER, Mr. A. SEDGWICK, Professor A. M. MARSHALL, Professor A. C. HADDON, Professor MOSELEY, *and* Mr. PERCY SLADEN (*Secretary*), *appointed for the purpose of arranging for the occupation of a Table at the Zoological Station at Naples.*

IN the Report read last year at Montreal, it was announced that a scheme was on foot for the building of a large physiological laboratory in connection with the Zoological Station at Naples, and for the purchase of a new sea-going steamer, to be equipped as a floating laboratory. Your Committee are now able to report that both these projects are steadily advancing towards attainment. For the physiological laboratory the Municipality of Naples has made a grant of 400 square mètres of ground, and the Italian Parliament has voted the sum of 50,000 lire towards the cost of building. Work is already commenced, and the plans show that the new laboratory will form an extension of the present handsome station, and will be carried out in the same style of architecture.

In addition to this assistance from the Italian Government, a Union of the maritime provinces of South Italy is about to be formed for the purpose of contributing towards the cost of the new laboratory, and of maintaining two tables there for the use of natives of the provinces concerned.

The exceptional advantages that a physiological laboratory connected with the Zoological Station will afford to investigators are too obvious to need recapitulation here; and Professor Dohrn will receive the congratulations of all biologists upon the patience with which his scheme, after years of anxious development, has been matured, and upon the success with which it has now been rewarded.

The new steamship, which it is hoped will shortly be in the possession of the station, will form a further and no less important addition to the capabilities of the establishment. The undertaking is in the hands of an influential committee in Germany, organised for the purpose of collecting subscriptions, and by whom the vessel will be presented to the station. It is intended that the steamer should be of 300 to 400 tons burden, with engines of 150 to 200 horse-power, and be fitted up in all respects as a floating laboratory. With such a vessel it will be perfectly practicable to remain weeks or months in any desired locality, and distance from home will be no obstacle, as the naturalists will live and work on board.

Biologists will call to mind numberless difficult problems that it will be possible by this means to investigate with every prospect of successful solution, which hitherto have remained unapproachable. The imaginary sketch of what might readily be accomplished by means of the floating laboratory, given by Professor Dohrn in a recently published report on the progress and prospects of the Zoological Station, reads almost like a naturalist's dream—a scientist's castle in the air—instead of the calm *résumé* of what will be reasonably possible in the near future so soon as the station is in possession of this veritable castle on the sea.

Concurrent with these greater strides of the Zoological Station, improvements in the general management, in methods of work, and in instruments of research are constantly being made, the details of which

would be too numerous to mention in this place. The general efficiency of the establishment is so well known that it will suffice to say that the whole organisation of the station is in a state of active and prosperous vitality. The best evidence of this is furnished by the accompanying lists: (1) of the naturalists who have occupied tables during the past year, and (2) of the publications resulting from work carried out at the station.

The General Collections.—Additions have been again received from Captain Chierchia, who has, since the last Report, sent two collections of specimens from the Pacific and Indian Oceans. Other collections have likewise been received from Lieutenant Cercone, Lieutenant Orsini, and Lieutenant Colombo, from the Atlantic, the Red Sea, and the Mediterranean respectively.

Some of the material previously obtained by Captain Chierchia has already been utilised by Count Béla Haller in a paper on the Molluscan kidney, recently published; and the same author is at present preparing a monograph on the Patellæ. In like manner, the Pteropoda have been investigated by Dr. Boas of Copenhagen, whose monograph upon the subject is now in the press.

The Publications of the Station.—The scientific importance and artistic beauty of these works are now so well known that comment would be superfluous.

1. Of the 'Fauna und Flora des Golfes von Neapel,' the following monograph has been published since the last Report:—XI. A. Lang, 'Polycladæ' (2te Hälfte: the complete work 688 pp., 39 plates).

The following works are in the press:—K. Brandt, 'Coloniebildende Radiolarien.' J. Fraipont, 'Polygordius.'

Monographs by G. von Koch on 'Gorgoniidæ,' and by P. Falkenberg on 'Rhodomeleæ,' will also shortly appear, the plates being now in the press.

2. Of the 'Mittheilungen aus der zoologischen Station zu Neapel,' vol. v. (580 pp., 32 plates), is complete, and contains numerous papers written in English; of vol. vi., parts i. and ii. are published.

3. The 'Zoologischer Jahresbericht' for 1883 (1,324 pp.) is published. The general arrangement and treatment of subjects are the same as mentioned in the previous Report. Sections 1 and 2 are edited by Drs. Paul Mayer and W. Giesbrecht, and sections 3 and 4 by Dr. Paul Mayer. The 'Bericht' for 1884 is in the press.

4. Of the Guide to the Aquarium, printed in German, English, Italian, and French, a second German edition has just been published, and a second Italian one will shortly be required. A supplement has also been printed in each of the four languages, in which the actual contents of every tank are enumerated, and references are given to the pages of the Guide and the accompanying illustrations. By this means the finding of any special animal, as well as the intelligent perusal of the Guide by the general public, is greatly facilitated.

Extracts from the General Report of the Zoological Station.—The usual lists and details, courteously furnished by the officers of the station, will be found at the end of this Report, and bear testimony to the constantly increasing activity of the station.

The British Association Table.—Since the last Report, the table has been occupied by Mr. Wm. E. Hoyle, who, although limited in time, was enabled to prosecute researches on the embryology of the Cephalopoda,

and to collect material from which important results may be expected. The report forwarded by Mr. Hoyle is appended.

An application for permission to use the table during the coming year has already been received, and others are expected. In view of these anticipations, and of the exceptional advantages afforded by the British Association table in the Zoological Station at Naples, your Committee most confidently recommend the renewal of the grant (100*l.*) for the ensuing year.

I. *Report on the Occupation of the Table, by Mr. William E. Hoyle.*

I reached Naples on April 6, 1885, and left on the 28th of the same month. In so short a time it was obviously impossible to make anything of the nature of a complete investigation in a subject of such magnitude and difficulty as the embryology of the Cephalopoda; it seemed, therefore, that the opportunities afforded me could best be utilised by collecting material for subsequent examination.

Of this I had an abundant and immediate supply, thanks to the kindly forethought of your Secretary, who had given notice to the authorities of the station of the nature of the work I had undertaken, so that they had a quantity of ova ready for my use.

The greater part of my time was spent in extracting embryos from the egg and preserving them in various fluids, and a fairly complete series of developmental stages of *Loligo* and a good many embryos of *Sepia* were thus obtained. When the young Cephalopods have reached a stage at which the rudiments of the arms are clearly visible, it is moderately easy, after a little practice, to extricate them by making an incision into the egg-membrane with a fine scalpel; but previously to this period they so nearly occupy the whole interior of the egg that it is almost impossible to obtain them uninjured.

A quantity of such eggs I preserved whole by a method suggested to me by Dr. Jatta, who is at work upon a monograph of the Cephalopoda of the Bay of Naples.

The strings of eggs are placed whole in weak solution of chromic acid (about 0·25 per cent.) for a few hours, and then in distilled water for twenty-four hours, after which they are preserved in alcohol. The embryos can then be extracted much more readily than when fresh.

Some time was devoted to examining and drawing the embryos in the fresh condition, and in watching the process of segmentation in *Loligo* and *Sepia.* I observed the presence of the 'Richtungsbläschen' in the former, which, so far as I am aware, has only been noted in a Russian memoir on the development of *Sepiola* by Ussow.

A number of blastoderms in process of segmentation were preserved according to a method proposed by Ussow, for the knowledge of which I am indebted to Dr. Edward Meyer, who kindly translated it for me from the original.

The egg, without removal of the membranes, is placed in 2 per cent. solution of chromic acid for two minutes, and then in distilled water, to which a little acetic acid (one drop to a watchglassful) has been added, for two minutes longer. If an incision be now made into the egg-membrane the yolk flows away and the blastoderm remains; if any yolk still cling to it, it may be removed by pouring away the water and adding more.

The blastoderms thus prepared show, when appropriately stained, fine karyokinetic figures, of which I hope shortly to publish an account.

The reduction of the collected embryos to serial sections and their examination will of course occupy some time, but I hope in a few months to prepare some account of the results obtained from them.

In conclusion, I have to express my thanks to the Committee for granting me the use of their table, as well as to the authorities of the Zoological Station for their kindness and courtesy to me during my work.

II. *A List of Naturalists who have worked at the Station, from the end of June* 1884 *to the end of June* 1885.

Report of the Committee, consisting of Professor McKendrick, Professor Struthers, Professor Young, Professor McIntosh, Professor Alleyne Nicholson, Professor Cossar Ewart, *and* Mr. John Murray (*Secretary*), *appointed for the purpose of promoting the establishment of a Marine Biological Station at Granton, Scotland.*

The Committee report that the sum of 100*l.* placed at their disposal has been expended in the maintenance and additional equipment of the Scottish Marine Station at Granton. The following report on the development and present condition of the station has been sent in to the secretary by Mr. J. T. Cunningham, the superintendent:

At the time of the last meeting of the British Association the laboratories and aquaria of the station were all contained in the floating establishment called the 'Ark.' Last autumn more spacious premises were acquired. These are situated on the shore not far above high-water mark, and only a few hundred yards to the east of the submerged quarry in which the ark was moored. The property when acquired consisted of a number of rough brick sheds surrounding a central yard, and had been used as a factory; it covers an oblong area about 147 feet in a direction parallel to the shore, by 78 feet in breadth. On the north side of the area now stands the building containing the laboratory and aquarium, the former occupying the upper storey, the latter the ground floor. The laboratory is divided into two parts by a partition, the western room serving principally as a museum. The building was constructed and the laboratory fitted in the autumn of last year. In the spring of the present year the system of aquaria was fitted up, the work having been commenced at the beginning of May and finished on June 17. The aquarium tanks are seven in number, and are constructed of wood. A row of five runs along the north side of the aquarium room; these are shallow, their dimensions being 8 feet by 6 feet by 1 foot 3 inches. They are arranged in a stair-like series, each being about 8 inches lower than its neighbour on the east side, and the water flows from the overflow-pipe of one to the other throughout the series. On the south side of the room are two deep tanks, each measuring 6 feet by 5 feet by 3 feet, and having the front partially formed of plate-glass.

The water to supply the aquarium tanks comes from a large reservoir, also of wood, fixed at a higher level than the roof of the aquarium room, in the shed to the east of the latter. The water overflowing from the aquarium tanks is delivered by means of indiarubber hose into a number of pits sunk into the ground; these are lined with cement, and roofed over in order to exclude dust and rain. They are situated at the west end of the central yard.

The circulation of sea water is maintained by a horizontal double-action pump, which is fitted up in a small building at the south-east corner of the premises. A suction pipe two inches in diameter connects the pump with the quarry, and opposite the pits before referred to the pipe is fitted with a stop-cock and hose coupling, so that the communica-

tion with the quarry may be shut off, and water pumped out of the low-level reservoir formed by the pits. The delivery pipe from the pump branches after some distance, one branch going to the high-level, the other to the low-level reservoir. The latter is used when it is required to pump water direct from the quarry to the low-level reservoir. The water is delivered into the deep aquarium tanks by four fine-glass jets. The highest shallow tank is supplied from an ordinary stop-cock, but there is also a pipe running along the wall at the back of the shallow tanks, fitted with a number of jets from which small vessels for isolation and experiment may be supplied.

The steam yacht *Medusa*, of fourteen tons burthen, which was built for the Station at its institution in April last, and is specially fitted for dredging and sounding, still forms the principal sea-going equipment. During the present year the services of a small lugger-rigged fishing boat have also been available. Investigations have been carried on at the Station in the three departments of Zoology, Botany, and Physics.

Up till the end of last June inquiries into the fauna and flora of the Firth of Forth were carried on regularly, by means of dredging and tow-netting and shore-collecting. During the six months following June 1884, Mr. J. R. Henderson, M.B., devoted the greater part of his time and attention to the speciegraphical and faunological work of the Station, and made a specially complete examination of the Crustacea; he obtained and identified fifty species hitherto unrecorded as occurring in the Firth of Forth. A paper on these species was published by him in the 'Proc. Roy. Phys. Soc. Edin.,' 1884–5. Dredging and collecting were continued in the Firth of Forth up till the end of June, and the results are recorded in the note-books of the Station. Mr. Cunningham's time has been much occupied in working at the embryology of teleostean fishes, and in attempts to elucidate the reproduction of Myxine; his work in faunology has been chiefly confined to the Chætopoda. The embryology of some pelagic eggs and that of the herring, together with the habit of the herring in the neighbourhood of the Firth of Forth, were investigated last year. In the first half of the present year a study was made of the development of the cod, haddock, whiting, and gurnard. Since then Myxine has principally received attention.

At the end of June last a summer branch of the Station was established at Millport. The Ark and the yacht were taken thither from Granton, through the Forth and Clyde Canal. The Ark was at first moored in Millport Bay, and afterwards drawn up on shore, and during the months of July and August dredging was carried on in the *Medusa* by Mr. Murray and Mr. J. R. Henderson, and zoological studies were pursued in the Ark by these and several other naturalists. Mr. Henderson was engaged during the whole time in the examination of the Crustacea, Echinodermata, and Polyzoa of the Clyde estuary. Mr. David Robertson, of Glasgow, availed himself of the resources and arrangements provided to pursue his studies of Ostracoda and other minute forms. He is preparing a complete systematic account of the Amphipoda of the Clyde for the Glasgow Natural History Society. The Rev. A. M. Norman spent a fortnight in zoological work at Millport, and Mr. Dendy, of Owens College, Manchester, worked for a time at the physiology of Comatula. At the beginning of September the yacht was brought back to Granton, where she arrived on the 2nd. The Ark has been left at

Millport in charge of Mr. David Robertson, who intends to place in it as complete a collection as he can make of the animals living in the Clyde estuary. The little laboratory will always be open to naturalists who wish to pursue any marine work at Millport.

As soon as the aquarium was in working order some investigations were begun as a preliminary inquiry into the questions concerning oysters in the Firth of Forth. The ultimate object of this work is to institute, if possible, a practicable system of oyster culture by which the beds of the Firth may be replenished. A number of oysters have been obtained from the neighbourhood of Inchkeith, and among these several were ascertained to contain spat in the mantle cavity. Unfortunately the supply of spatting oysters was small, practical experience in the work was wanting at the beginning of the experiments, and the time which could be devoted to the matter was limited. No oysters have been obtained which contained mature spat—that is to say, spat ready to escape from the parent and enter upon the free swimming condition. Consequently the crucial experiments of placing free larvæ, under various conditions, in order to discover a method of obtaining fixed spat with some certainty, have not yet been made; probably no other opportunity will occur until next season. The inquiry into the conditions of oyster culture is somewhat expensive; the oysters themselves cost money, and it is necessary continually to invent and fit up aquaria with different arrangements, in order to test the effect of various conditions. One experiment which ought to be tried next season, and cannot be arranged without considerable expense, is that of keeping some brood oysters and larvæ at a somewhat high temperature, viz., 68° F., which the water in the Firth of Forth scarcely ever reaches. The inquiries carried on in Holland have shown that that temperature is most favourable to the fertility of the parent oyster and the health of the spat. Another experiment which ought to be made is that of enclosing oysters in a marine pond connected with the sea, and endeavouring to collect the spat. The station ought also to have exclusive control over some area of sea bottom suitable for the growth of oysters, in order to try and produce a new and populous oyster bed.

The work of the Station in the Zoological department is only at its beginning. The examination of the data which have been collected with regard to the occurrence of the various species in different parts of the Firth has not yet been made, owing to the pressure of other work. Some progress will be made in this during next winter. Mr. Sloan is devoting much energy to the study of the Cœlenterates, which have been little worked in Britain for some years. The examination of the Chætopods has been already carried out with some completeness. In the new aquarium excellent opportunities are afforded for the study of development. A number of glass vessels have been so arranged that a current of water is continually passing through them, and yet even very small eggs and larvæ cannot escape. This plan has been found the only one reliable for keeping small creatures alive for a long time. However carefully an aerating apparatus is arranged, it is extremely difficult, if not impossible, to prevent the contamination of an isolated quantity of water by the bodies of the specimens that die.

Since the opening of the Station a considerable number of persons have availed themselves of its resources to pursue studies and researches in zoology. In August of the present year Mr. C. F. Marshall, of the

physiological laboratory of Owens College, Manchester, carried out at the Station a series of experiments on the function of the nerve trunks in the lobster, and also studied the histology of muscular tissue in different classes of animals.

During the greater part of August Miss Maconnish, of London, studied in the laboratory. The following is a list of those who have visited the station for the purpose of study and research since its opening:—In 1884, Prof. W. A. Heardman, Univ. Coll., Liverpool, April; Mr. J. R. Davis, Univ. Coll., Aberystwyth, July; Miss Maconnish, London, Aug. and Dec. In 1885, Mr. John Boyd, Manchester, April, few days; Mr. D. M. Stewart, Edinburgh, May 28 to July 28; Dr. Burn Murdoch, Edinburgh, May to July; Dr. J. A. Thomson, M.A., Edinburgh, July 1 to July 28; Dr. Kelso, Edinburgh, July 3 to July 20; Miss Maconnish, London, July 27 to Aug. 25; Mr. J. L. Smith, M.A., Edinburgh, July 30 to Aug. 8; Mr. A. D. Sloan, Edinburgh, Aug. 8 to present time; Mr. C. F. Marshall, B.Sc., Owens Coll., Aug. 17 to Aug. 30.

The following is a list of the papers which have been published by the Zoological department of the Station:—

Critical Note on the Latest Theory in Vertebrate Morphology, 'Proc. Roy. Soc. Edin.,' vol. xii. 1884.

Additions to the Fauna of the Firth of Forth, 'Proc. Roy. Phys. Soc. Edin.,' 1884–85.

Nature of Kupffer's Vesicle (Herring Ovum), 'Proc. Roy. Soc.,' 1884; also in 'Quart. Journ. Mic. Sci.,' Jan. 1885.

Relations of Yolk to Gastrula in Teleostean Ova (Cod, Haddock, Whiting, Gurnard), 'Quart. Journ. Mic. Sci.,' 1885; and 'Proc. Roy. Soc. Edin.,' 1885.

In Botany the flora of the Firth was systematically investigated by Mr. Rattray up till the beginning of June of this year. A collection of the Algæ in the area has been made and systematically arranged. The results of the work were published in several papers on the marine flora of the Firth of Forth, communicated by Mr. Rattray to the Botanical Society and the Royal Society of Edinburgh.

The following is a list of the papers referred to:—

On the Geographical Distribution of Algæ in the Firth of Forth, 'Trans. Bot. Soc. Edin.,' 1884–85.

On the Algæ of Granton Quarry, *ibid.*

The May Island, its Algoid Flora, &c., *ibid.*

On some New Cases of Epiphytism among Algæ, *ibid.*

Observations on the Oil Bodies of the Jungermannieæ, *ibid.*

Note on Ectocarpus, 'Trans. Roy. Soc. Edin.,' Feb. 1885.

Preliminary Note on the Evolution of Oxygen by Algæ, 'Trans. Bot. Soc.,' 1884–85.

The last mentioned paper contained an account of a series of experiments conducted by Mr. Rattray, with a view of discovering and comparing the rate of the production of oxygen by seaweeds of different colours and different species. The oxygen was estimated by means of absorption of the carbonic acid and the oxygen, in a graduated tube over mercury. The gas evolved by the Algæ was collected in large glass tubes full of water, containing the Algæ, and exposed to light.

In the department of Physics and Chemistry the work carried on by Mr. Mill has consisted in the systematic investigation of the temperature and salinity of the water of the Firth of Forth at different seasons and

different places. A new mechanical arrangement for inverting the Negretti & Zambra self-registering thermometer was invented soon after the work was begun; the original arrangement was found to be unsuitable for work on board a small steamer in shallow water where the currents were rapid. In the new frame the inversion is effected by the fall of a messenger along the line upon a horizontal lever. The mechanism was explained by Mr. Mill, in a paper communicated to the Royal Society of Edinburgh in July 1884. For taking samples of water at different depths, a modification of Mr. Buchanan's slip-water bottle is used. The alteration consists in the fact that the slip cylinder, instead of being allowed to run down the line from the hand of the observer, is suspended just above the frame by a spring lock, and is released by the fall of a messenger sent down from the deck of the ship.

In the summer of 1884 an inquiry was made, by means of a number of series of observations at short intervals, into the tidal variation of temperature in the Granton Quarry. The result was communicated to the Royal Society of Edinburgh. The temperature and salinity variations in the Firth were investigated by means of trips on the *Medusa* up and down and across the Firth. The results of the work are published in a paper entitled 'On the Salinity of the Firth of Forth,' 'Proc. Roy. Soc. Edin.,' vol. xiii. On various occasions when the yacht has visited the Clyde observations have been made on the temperature and salinity of that estuary. Some observations have also been made into the physical conditions of the Tay and the Tweed. During the present summer, the months of July and August have been spent by Mr. Mill in similar work at the mouth of the River Spey. A *résumé* of the work which he has so far accomplished in investigating the physical conditions of Scottish estuaries is to be read by Mr. Mill before the present meeting of the Association.

In July of the present year a very thorough investigation was made at the Station, by Mr. H. N. Dickson, of the properties of a number of new thermometer screens invented by Mr. John Aitken, of Darroch. The aim of the inventor was to devise some form of apparatus which should eliminate the causes of error present in the ordinary Stevenson screen, now in general use for meteorological observation. Mr. Dickson gave an account of his researches to the Scottish Meteorological Society, and also to the Royal Society of Edinburgh. Some of the instruments have been taken to the Ben Nevis Observatory, where their investigation is being continued under different conditions.

The Marine Station is one of the regular observing stations of the Scottish Meteorological Society; the ordinary observations on the air and the temperature at the surface and bottom of the quarry are recorded twice daily, and the records forwarded to the society's secretary.

J. T. CUNNINGHAM.

The Committee beg to recommend the renewal of the grant (100*l.*) for the ensuing year.

Report of the Committee, consisting of Sir LYON PLAYFAIR, Professor MOSELEY, Admiral Sir E. OMMANNEY, Mr. P. L. SCLATER, *and* Mr. A. SEDGWICK (*Secretary*), *appointed to prepare a Report on the Aid given by the Dominion Government and the Government of the United States to the encouragement of Fisheries, and to the investigation of the various forms of Marine Life on the coasts and rivers of North America.*

IN Canada there is a *Department of Fisheries*, presided over by the Minister of Marine and Fisheries, to whom a Deputy Minister of Fisheries makes an annual report.

'The duties of the Department of Fisheries consist principally in the administration of all laws relating to the subject of the sea, coast, or inland fisheries; the management, regulation, and protection thereof; and all matters and things relating thereto, or assigned by the Governor in Council to the said department.' [1]

The total expenditure of this department for the year ending June 1884 was $116,531, distributed as follows:—General service, $69,011; fish breeding, $27,585; maintenance of fisheries, protection steamer *La Canadienne*, $19,935.

There are twelve fish-hatcheries in the Dominion, on which the expenditure by the department was in 1884, as stated above, $27,585. Over 53 million fry—chiefly of salmon, trout and white-fish—were turned out from these establishments in 1884.

The United States Fish Commission was instituted in 1871. Its object, as defined by Congress, was as follows:—'To prosecute investigations on the subject of the diminution of valuable fishes, with the view of ascertaining whether any and what diminution of the number of food fishes of the coasts and lakes of the United States has taken place, and if so to what cause the same is due; also, whether any and what protection, prohibitive or precautionary measures in the premises, and to report on the same to Congress.'

To enable it to attain these objects, an appropriation was made to the Commissioner.

In every year since 1871 appropriations have been made by Congress to the Fish Commissioner, to enable him to carry out his recommendations; and the sums voted have increased year by year, until, in 1884, the sum of $245,380 was appropriated.

The following table shows the annual appropriations to the Fish Commissioner since 1871:—1871–72, $9,000; 1872–73, $30,000; 1873–74, $38,500; 1874–75, $23,500; 1875–76, $71,000; 1876–77, $36,045; 1877–8, $75,700; 1878–79, $71,000; 1879–1880, $157,000 (includes $57,500 for steamer *Fish-Hawk*); 1880–81, $121,500; 1881–82, $328,710 45c. (includes $12,709 for *Fish-Hawk* and $145,000 for *Albatross*); 1882–83, $233,319 60c. (includes $45,000 for *Albatross*); 1883–84. $242,500 (includes $10,000 for *Albatross*); 1884–85, $245,380. Total since 1871, $1,683,155 5c.

[1] *Annual Report of the Department of Fisheries of the Dominion of Canada for the year* 1884.

Special appropriations for the International Fishery Exhibition in Berlin, \$20,000 ; ditto in London, \$50,000.

Additional assistance given by Congress and not included in the above sums:—

1. Extensive fish-ponds for breeding by the construction of piers in the sea at Wood Holl, Mass., the headquarters of the Commissioners (in course of construction in 1884) ; estimated cost, \$80,000. Of this sum \$50,000 has already been voted as part of the Harbour Improvement Appropriation.

2. The pay of the officers and men of the United States navy who work the Fish Commission steamers *Albatross* and *Fish-Hawk,* the former being chiefly equipped for ocean, and the latter for coast work. In addition, the navy has general instructions to give such aid as they may be able to the Commission when their ships are in available waters.

3. Printing of the annual report of the Commissioner and of the Bulletin [1] of the United States Fish Commission.

Fish Commission of the various States of the Union.

In addition to the assistance given by the Federal Government 'to the encouragement of fisheries, and to the investigation of the various forms of marine life on the coast and rivers of North America,' thirty-one States had in 1882 their own Fish Commissions, subsidised in each case by annual appropriations from the State Government.

The total sum appropriated in this manner in the year 1882 was \$120,948, and the total amount appropriated since the institution of the State Fish Commissions was, in 1882, \$1,101,096.

Report of the Committee, consisting of Professor HUXLEY, Mr. SCLATER, Mr. HOWARD SAUNDERS, Mr. THISELTON DYER, *and* Professor MOSELEY (*Secretary*), *appointed for the purpose of promoting the establishment of Marine Biological Stations on the coast of the United Kingdom.*

THE Committee beg leave to report that they have received the sum granted (150*l.*) from the Treasurer of the Association, and have paid it to the funds of the Marine Biological Association of the United Kingdom, as the most direct means of promoting the speedy establishment of a marine laboratory in a most favourable situation on the British coast—namely, Plymouth. An excellent site for a laboratory has been granted to the Marine Biological Association by Government, at Plymouth. A sum of 8,000*l.* has been raised by subscriptions and donations, the Government has promised to aid the working of the laboratory by an annual subsidy, and there is every prospect of success. It is probable that the building of the laboratory will commence in November.

[1] 'Resolved by the Senate and House of Representatives of the United States of America in Congress assembled, that the public printer be and he hereby is instructed to print and stereotype, from time to time, any matter furnished him by the United States Commissioner of Fish and Fisheries relative to new observation, discoveries, and applications connected with fish culture and the fisheries, to be capable of being distributed in parts, and the whole to form an annual volume or bulletin not exceeding 500 pages. The extra edition of said work shall consist of 5,000 copies, of which 2,500 shall be for the use of the House of Representatives, 1,000 for the use of the Senate, and 1,500 for the use of the Commissioner of Fish and Fisheries.'

Report of the Committee, consisting of Dr. H. C. Sorby *and* Mr. G. R. Vine, *appointed for the purpose of reporting on recent Polyzoa. Drawn up by* Mr. G. R. Vine.

Report on Recent Marine Polyzoa; Cheilostomata and Cyclostomata only.

Part I. Introduction.

In the present Report I have been compelled to adopt a classification somewhat different from that which I followed in my Fifth Report on Fossil Polyzoa (1884). Since the first publication of the Report, Mr. George Busk's long-expected *Challenger* monograph (Cheilostomata) has appeared, and as his scheme of classification differs from that of Mr. Hincks, both in the 'British Marine Polyzoa,' and also in the 'Contributions towards a General History of the Marine Polyzoa,' I have thought it best to allow each author to speak for himself, rather than to try to harmonise or alter the text, except by the scheme adopted farther on.

In his Introduction to the *Challenger* Report, Mr. Busk remarks, 'that although many of the family groups may in some measure be regarded as expressing natural alliances,' others can only be considered as artificial, 'especially in the sub-division C, or Escharina . . . . and as such they must perhaps remain until we are better acquainted with the true significance of the minute parts or organs upon which the distinctive characters are in many cases founded . . . . Nevertheless, in order to place myself as far as possible in accord with modern views, I have, in the heterogeneous Family Escharidæ more especially, adopted partially the nomenclature proposed by Mr. Hincks and Professor Smitt; but in doing this I have found it impossible to avoid a certain amount of the confusion necessarily incidental to an attempt to graft a new system upon an old one based on a different set of characters.'

It will be remembered that in the arrangement of his families and genera in the 'British Marine Polyzoa,' and in his subsequent papers in the 'Annals and Magazine of Natural History,' Mr. Hincks sets a very high value on zoœcial characters. Mr. Busk also, in the *Challenger* Report, appreciates to a large extent this method in dealing with special groups; at the same time he says we are not 'in a position fully to appreciate the relative value of the *zoœcial* as compared with the *zoarial* characters . . . the individuality of the zoarium as a continuous whole or entity having been too much overlooked in the almost exclusive consideration of its component parts or segments.'

In the following 'Scheme of Classification' all the family names and divisions are the same as those used by Mr. Busk, with the exception of Family VII. *Notamiidæ*, which was founded by Mr. Hincks for the placement of a very peculiar polyzoon. There are also parts of the families Porinidæ and Myriozoidæ still unaccounted for in the arrangement adopted. These I treat of separately, out of deference to Mr. Hincks and others who have followed his arrangement, formulated for his work on British Marine Polyzoa.

Before passing on to the Classificatory List, it will be better, I think, to give a brief digest of the terms used by Mr. Hincks and by Mr. Busk, in the prefaces to their systematic arrangements both in the British Marine Polyzoa and in the *Challenger* Report. For obvious reasons I do not specially commit myself to remarks on the systematic arrangements of authors previous to the issue of these two works. In my former reports on Fossil Polyzoa I have pointed out the varied lines of investigation followed by other authors in their methodical classifications, but these are most noticeable in the arrangements of Reuss and Manzoni on the fossil species, and by Professor Smitt in his various works on Recent Polyzoa, full digests of which were given in my fifth report.

TERMINOLOGY, according to the Rev. Thomas Hincks and Mr. George Busk.

ZOŒCIUM.—(=*Cell. Cystid.* Nitsche: *Brutkapsel*, Reichert). The chamber of the polypide.

ZOARIUM.—(=*polyzoarium* auctt.). The composite structure formed by repeated gemmation.

OŒCIUM.—(=*ovicell* auctt.)—The special receptacle attached to the zoœcium, in which the ova complete their development into the larva.—*Cheilostomata.*

GONŒCIUM.—A modified zoœcium set apart for reproductive functions. *Cyclostomata.*

GONOCYST.—The inflation of the surface of the zoarium, in which the embryos are developed.

Mr. Hincks (Introduction, p. iii, note), speaks of the ovicell as a 'marsupium,' and he restricts the use of the term *Oœcium* for *Cheilostomatous* Polyzoa. The modified reproductive cell of *Crisia* and the superficial inflation of the zoarium of many of the *Cyclostomata*, being different structures, should be distinguished by separate names.

Mr. Busk, in his *Challenger* Monograph (pp. xvi to xviii), employs certain terms in a particular sense.

I. ZOARIUM dimorphous: that is, erect or free: decurrent and encrusting, and more or less closely attached.

II. ZOŒCIA, surface—

1. Smooth.
2. Polished.
3. Granular.
4. Verrucose.
5. Rugose.
6. Pitted.
7. Punctulate, minutely porous.
8. Punctate, with larger perforations.
9. Reticulate.

Orifice,

1. Orbicular.
2. Elliptical.
3. Semi-orbicular.
4. Crescentic.
5. Coarctate.
6. Trifoliate.
7. Clithridate.

The lower border may be—

1. Entire, sinuous or straight.
2. Mucronate.
3. Emarginate.
4. Dentate.
5. Bi-dentate.
6. Incised.

The peristome may be—

1. Thin or thick.
2. Elevated, produced, or bevel.
3. Armed with oral spines, either rigid or articulated.
4. Unarmed.

The other divisions of this part of Mr. Busk's work refer to :—

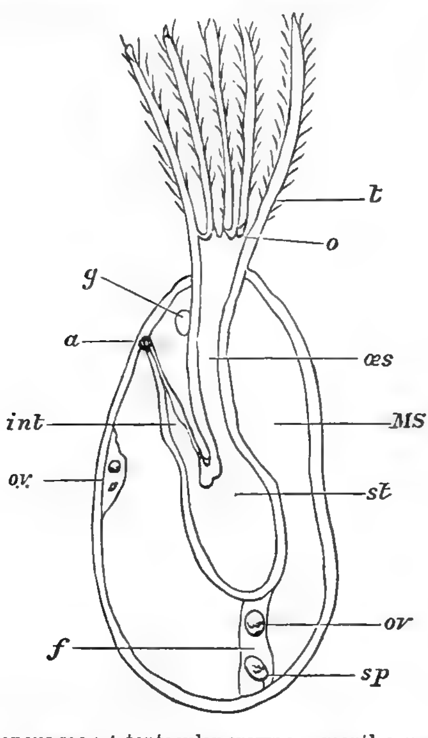
III. Special pores on the front of the zoœcia.
IV. The Oœcia.
V. Special organs : *a. Avicularia,*
§ as to function. | §§ as to position.
b. Vibracula : *a.* simple, *b.* compound.
VI. Chitinous elements.

Opesia, *Dr. Jullien.* Certain of the Membraniporæ having a thick calcareous expansion were covered when living by a membrane, in which was the opercular opening. This is the 'opesia' or opesial opening of Dr. Jullien.

Aperture—restricted for the proper opening.

General Plan of Structure.

'In every polyzoon,' says Mr. Hincks, 'we distinguish two fundamental elements, the zoœcium and the polypide. These are the primary



MS, membranous sac ; *t*, tentacular crown ; *o*, mouth ; *œs*, œsophagus ; *st*, stomach ; *a*, anus ; *int*, intestines ; *g*, ganglion ; *f*, funiculus ; *ov*, ovary ; *sp*, spermary. (After Hincks).

zooids in every colony. When the larva fixes itself, after its brief term of free life, it is metamorphosed into a single sac or cell, enclosing a mass

of formative material and certain rudimentary elements, out of which a polypide is developed. These two constitute together the primary term (Hks.) [germ ?],[1] of a colony; and by repeated buddings, according to the pattern of the species, the composite zoarium is built up. The colony is formed by the indefinite repetition of the primitive zooids and their modifications.'—Brit. Mar. Poly. p. iv.

I. Zoœcium.

In dealing with the zoœcium in the various aspects which it presents to the student in its dried condition it may be well to mention one or two particulars before passing on to special details. In studying the Fossil, in connection with the Recent Polyzoa, great caution is necessary in making observations on abnormal forms. In the living state we have more than one character to guide us in our deliberations; but in the dried state, or in the fossil, very often large portions of the outer crust are so calcified that sometimes only the mouth of the cell is visible; possibly oœcia or avicularia, hence the necessity of some such plan of classification as that afforded by Mr. Hincks, based on persistent characters. Mr. Waters, in following Mr. Hincks, when studying the Australian fossil Bryozoa, had occasionally the merest fragment of a colony to deal with; and had it not been for certain facts on which he could rely with safety, his task must have been almost a hopeless one. These remarks, however, apply more particularly to Cheilostomatous groups, such as the MEMBRANIPORIDÆ and the ESCHARIDÆ of Busk, together with some allied genera which will be specially referred to.

In many cases the primary cells in colonies of the MEMBRANIPORIDÆ are peculiarly shaped. For the most part they are somewhat rounded, with a large terminal aperture closed in by a membrane and usually surrounded by a number of spines. Van Beneden described such a form by a distinct generic term, that of *Tata*, and in connection with the study of fossil Colonial growths the *Tata* stages of the zoarium are very interesting. Mr. Waters met with some peculiarities in the Australian Bryozoa, and I have met with a few examples in the Cretaceous—Eocene —Miocene, Crag and Post-pliocene *Membranipora* of Mr. Hincks. This group, however, is broken up by Mr. Busk in his *Challenger* Report, and particulars of the genera, and the characters upon which these are founded, are given in the body of the present report.

In the zoœcia of *Megapora* there is a depressed area surrounded by a raised margin, and partially closed in by a calcareous lamina. The aperture is trifoliate, the upper portion surrounded by spines, similar in some respects to *Cribrilina radiata* and *Microporella ciliata*. The depressed area with the raised margin separates the genus from the other genera in this respect, but there are some points of resemblance between *Megapora ringens*, and the *Membranipora Flemingii* of authors, and the species Mr. Hincks thinks ought to be included in the genus Megapora. This latter species has also a trifoliate orifice, but the spines of the fully developed cell are very different—so also are several other features—of the matured and immature cell.

In the *Challenger* Report Mr. Busk makes the *Membranipora Flemingii*

[1] 'Term' is used by Hincks, but this may be a misprint for the bracketed word [germ ?].

of Hincks, and others, the type of his genus *Amphiblestrum* Gray, and he places in the group six species, four of which are described and figured in the report, the other two referred to and redescribed. The trifoliate character of the orifice is not found in the whole of Mr. Busk's species; some orifices are obovate, but all have a partially internal calcareous lamina. So that in dealing with the two groups—*Megapora* and *Amphiblestrum*—we shall have to deal with other characters besides that of the trifoliate orifice. In all probability the one or the other peculiarities of the group date back to the Upper Chalk, but in a very modified form as regards species.

In the MICROPORIDÆ the front wall of the zoœcia is wholly calcareous, but the margins are elevated and there is a slight tendency to trifoliation in *M. complanata*, but there are no marginal spines. In his papers on Australian Bryozoa Mr. Waters places two or three forms in this genus, and he alludes to one form as *M. hippocrepus*, Goldf. None of the species, however, are to be compared with the semitrifoliate orifice of *M. complanata*, Norman=*Membranipora Smitti*, Manzoni. We thus carry back the partially trifoliate orifice to the Italian Pliocene, but we also find it, together with other characters, in *Membranipora trifolium* in the Crag.

In *Steganoporella* there is in the orifices of some of the cells a slight tendency to trifoliation; but there are other marked characters which separate the species from *Micropora*, although the external aspect of forms of the two genera are similar. Only one species is described by Mr. Hincks, *S. Smittii*, but in describing *S. magnilabris*, Busk, *Chal.* Rep., Mr. Busk re-defines and limits the genus and species. 'The chief character on which the genus *Steganoporella*, Hincks, ... is based is the bithalamic condition of the zoœcium. Some way below the upper extremity of the cell a diaphragm shuts off the lower portion of the cavity, and forms a distinct chamber for the polypide. A tubular passage extends upwards from this chamber, and opens . . . . into the upper chamber, which is always large, and in certain cells of very ample dimensions . . . . The opening of this chamber is closed by a very large operculum . . . . which also protects the entrance to the tubular passage through which the polypide issues.' (Hincks' 'Annals,' Feb. 1882, p. 83.) 'Smitt places *Steganoporella* amongst the Microporidæ . . . . but I am now inclined to agree with Dr. J. Jullien so far as to regard the dithalamic condition of the zoœcium, which distinguishes it, as entitling it to rank in a separate *family* group'—Fam. Steganoporellidæ, Hincks. (Annals, May, 1884, p. 358.) I have preferred to give, on this point especially, both the first-formed and matured expressions of the author.

Another very important group which seems to be far more natural that the last is the MYRIZOIDÆ, Smith and Hincks. It contains the genera *Schizoporella*, and *Mastigophora*, of Hincks, and its distinguishing feature is the sinus on the lower margin of the orifice. The sinus is also found in species of *Hippothoa* which Mr. Hincks places in the family, but notwithstanding this Mr. Busk (*Chal. Rep.*) removes it and places it with his stoloniferous group, particulars of which are given in the body of the present report. But as in other groups, so in this, dependence in the divisions must not be placed upon one character alone; other characters must be considered as well as this, and the systemist would do well to look all around his species before deciding to which group it belongs. The sinus of *Schizoporella spinifera* is very much like the sinus of *Smittia marmorea*; so also is the orifice, excepting the spines in the former species.

But the remarkable development of other characters in *Smittia*, *Schizoporella*, and *Mastigophora Hyndmanni* increases the interest in the study of the zoœcium having a sinuated lip. The group, however, has had a wonderful history, for it reaches back to the Cretaceous epoch, and many and diverse are the fossil forms of the older authors which are now regarded as synonyms of well-defined recent species. Taking only one, *Schizoporella unicornis*, Johnson, no fewer that nine species—or even more if we include the varieties, some of which are fossil forms—are placed as synonyms. In his papers on the Australian Bryozoa, Mr. Waters describes a number of species belonging to the genus *Schizoporella*, and Mr. Busk adds additional particulars in his *Challenger* Report.

Species belonging to the MICROPORELLIDÆ of Hincks demand a closer and more critical study than they have yet received. Not so much on account of the orifice—which is more or less semicircular with margin entire, but on account of the semilunate, or circular, pore on the front wall. There is connected with this pore a physiological mystery, and there seems to be as yet no possibility of its solution. One species that I have just described in the Jesson collection (Cambridge Greensand) [1] seems to be related to the group, but we have forms in the Carboniferous rock which apparently belongs to this, or some allied group not represented in the Mesozoic rocks. These, however, we place at present with the Cyclostomata.

In the closer study of species which possess this pore below the orifice Mr. Busk has felt himself compelled to establish two families—the ONCHOPORIDÆ and ADEONEÆ—for two different groups in which this peculiar feature is present. In remarking on Onchoporidæ (*Chal. Rep.* p. 102), Mr. Busk says: 'Considering, as Mr. Hincks remarks truly, that we do not know the physiological import of the lunate pore, and that the form of the mouth (in *Microporella*) is common to a vast number of species, I am not at present inclined to agree with him in regarding these two characters, even in combination, as alone sufficient to justify the association of such otherwise very dissimilar forms as *Onchopora Sinclairii* and *Onchoporella bombycina*, Busk, &c., with the Lepralian Microporellidæ.' And again, in his elaborate introductory remarks on the family Adeoneæ (*Chal. Rep.* p. 178): 'The presence of a median pore or its equivalent, which though not formed in the same way in all the Adeoneæ, doubtless subserves the same function in all, and in every case appears to me to differ widely in nature from the lunate pore in *Onchopora*, *Microporella*, &c., as well as from the tubular pores of *Tessarodoma*, *Tubucellaria*, &c.' I had prepared several original remarks on these pores which I had made in a study of the *Microporella*, *Onchopora*, and *Adeonea* in my cabinet; but I thought that the authority of Mr. Hincks, Mr. Waters, and also of Mr. Busk on the same subject would appear with much better grace in this introductory part. Nevertheless I should strongly direct the attention of students to this subject, especially upon species from new localities.

In his remarks on a specimen of *Microporella fuegensis*, Busk (Burmese coast), Mr. Hincks says that 'the sub-oral pore presents some peculiarities. It is placed *immediately* below the rim of the orifice in front, and is only found in the adult cell. In the marginal zoœcia the orifice is sub-orbicular and the peristome not elevated; but in a more

[1] *Abstracts in Proceedings of the Geo. Soc. of London*, No. 470, p. 74.

advanced stage the peristome rises considerably round the back and sides of the orifice, but not in front, the result being that a sinus is formed here. In a still more advanced stage the *margin* of the side wall of the peristome is extended across the upper part of this sinus, forming a narrow rim, and converting the open fissure into a circular pore, which communicates directly with the interior of the tubular peristome.'—*Annals*, May 1884, p. 360.

The zoœcia of the CRIBRILINIDÆ appear to me to afford a good basis for a natural group, though the area of the cell varies very much in the different species. The zoœcial features, however, are very peculiar, and the forms that are grouped together in the family are beautiful in the extreme. In many—both fossil and recent—the whole front of the cell below the orifice is either fissured, or marked by rows of punctures without fissures. Both the *Cribrilinæ* and the *Membraniporella* are widely distributed in the present seas; but only the first of these genera are found, so far as is known to me up to date, fossil, and very full particulars of the species are given in my Fifth Report on Fossil Polyzoa.

Much might be said about the zoœcia having the mucronate character in the lower lip of the orifice of Mucronella (Hincks), only that I have referred to several remarkable features in the species found in the *Challenger* dredgings.

For his own justification in the plan of classification adopted by Mr. Hincks in his 'British Marine Polyzoa,' the author says, in his preliminary essay[1] on the subject: 'The essential structure of the individual cell must certainly be accounted the most important point, both in itself and as a clue to relationship. . . . Unless we are content with the old (and certainly very simple) method of lumping all erect forms together, without any reference whatever to the cell, we have only a choice between these two courses: to found genera for the variations of growth, as well as for the more important modifications of the cell in each family; *or to make the zoœcium the basis of the genus, and treat the ordinary variations of habit sub-sectionally.* I was at one time inclined to the former method;[2] but further experience of the practical work of classifying the Polyzoa has brought me to a much greater extent into sympathy with Professor Smitt's views.' Much, however, remains to be done before our groups will be wholly satisfactory, as will be seen when the student takes up the study of the different families, genera, and species enumerated in the present report.

There are in the zoœcium several structural characters, such as communication-pores—avicularia—avicularian chambers, &c. These ought to be specially studied, and seeing what admirable work has been done in this direction by Mr. Waters and Mr. Busk, I can only say that, with all our knowledge, much remains to be done.

A very special study has been given to the zoœcium of Catenicella by Mr. Waters (Quart. Journ. Geo. Soc. vol. xxxix. pp. 423–429) some particulars of which are given in the text of the present report, but for fuller details, attention is directed to the paper itself, especially so as in the same paper Mr. Waters (p. 425) gives some account—all too briefly, though—of his views on the function of the avicularia. He also refers to the classification of the Membraniporæ proposed by Dr. Jules Jullien.

[1] *Ann. Mag. Nat. Hist. Ser.* 5, vol. ii. 1879, p. 160.
[2] *Ibid.* Dec. 1877, p. 523.

As to the zoœcia of the Cyclostomata it is not necessary to make any lengthy remarks here. In treating of this division of my subject, I have given very full particulars in my fourth and fifth reports, and I must refer the student to these for special details, and in that division of my subject in the present report—Cyclostomatous Polyzoa—I have given additional particulars. These for the present must suffice, until I have completed certain investigations into the structural peculiarities of the zoœcia in Palæozoic Polyzoa. There are, however, certain peculiarities connected with the study of the Ctenostomatous cell and its stoloniferous processes that may merit some consideration at least. But these details have been so ably worked out by Mr. Hincks in his 'History of British Marine Polyzoa,' especially in the description of species, that I refer the student without the least hesitation to the work itself, especially so as I am not able to touch upon the Ctenostomata in this report.

II. Zoarium.

I cannot blame Mr. Hincks for his adoption of zoœcial, in preference to zoarial, characters, as a basis of generic distinction. Still at the same time, as Mr. Busk asserts in the passage already quoted from the *Challenger* Report, 'it would be wise to take, at times, into consideration some of the zoarial features, modes of growth, and peculiarities of development in the zoarium, not as a basis of classification, but as a means of arriving at some conclusion that would help us to understand the close, or remote, relationship of the Palæozoic with Recent Polyzoa.' This study, however, must be carried out with Cyclostomatous rather than with Cheilostomatous groups, for I know of no form of polyzoa in the older rocks that would afford us true links of relationship with the latter recent group, or even with the modified zoarial Cheilostomatous structures of the Mesozoic age. Well-developed Cheilostomata are abundant in the Cretaceous rocks, both of this and other countries, and the peculiarities of growth may have been, at times, too much relied upon by authors. On this point I cannot help quoting a passage from the first of the series of papers on Australian Bryozoa by Mr. Waters.

'Probably no naturalist at all thoroughly acquainted with the Bryozoa will again attempt to sustain such genera as the old *Lepralia* and *Eschara*; but it may be well to examine carefully the growth of the Bryozoa before we entirely reject the form of the colony as of classificatory value; for in many cases it may be shown in this way from which part of a zoœcium the following zoœcium grows. The mode of growth of *Lepralia* and *Eschara* indicate no structural difference, for the young zoœcia in both grew out from the same part of the parent cells, and *Eschara* was only formed of *Lepralia* cells, back to back, often very slightly attached. . . . The form of the aperture must be the first consideration; but especially among fossils we must carefully notice how they grow.' (Quart. Jour. Geo. Soc., vol. xxxvii. p. 311).

III. The Polypide.

Of the Polypide it seems to be almost folly to speak in a report like the present one, as I have had to deal more particularly with the homes of the animal, rather than with the animal itself. Still at the same time I cannot allow the report to pass from my hands without making some reference to the polypide, for no very clear idea of the beauty of the zoœcia

can be obtained without we make a partial study as to how the cell is built up by the polypide. For the purpose of this study I know of no better training than the mastery of the details furnished by Barrois on Embryology, both of Cheilostomatous and Cyclostomatous Polyzoa, and after this the study of mounted or living specimens of *Carbasea* for the Cheilostomata, *Zoobotryon pellucidus*, Ehrenb., for the Ctenostomatous, and *Crisia* or *Hornera* (*Retihornera*, Busk) *foliacea*, Macgil., for the Cyclostomatous groups. In the first and second the endosarc and growth and development of the cells may be conveniently studied, and according to the character of the specimens, the growth and development of the polypide, and in the latter group the periodical growth of the cell and of the intercellular tubes, as noted by Busk ('Crag Polyzoa') and by Mr. Waters ('Australian Bryozoa: Cyclostomata,' Quart. Jour. Geo. Soc., vol. xl. p. 675 &c.)

Classification of Marine Polyzoa. Busk *and* Hincks (part).

Sub-order. **CHEILOSTOMATA**, *Busk.*

Division I. STOLONATA, *Carus.*

Family I. **Æteidæ.**

Genus 1. Ætea.

Family II. **Eucratiidæ.**

Genus 2. Eucratea.
„ 3. Hippothoa.
Genus 4. Pasythea.
„ 5. Brettia.[1]

Family III. **Chlidoniadæ.**

Genus 6. Chlidonia.

Division II. RADICELLATA.

Group A. Cellularina.

Family IV. **Catenariadæ.**

Genus 7. Catenicella.
Genus 8. Catenaria.

Family V. **Cellulariidæ.**

Genus 9. Cellularia.
„ 10. Menipea.
„ 11. Emma.
„ 12. Scrupocellaria.
Genus 13. Canda.
„ 14. Nellia.
„ 15. Caberea.

Family VI. **Bicellariidæ.**

Genus 16. Bicellaria.
„ 17. Bugula.
„ 18. Kinetoskias.
Genus 19. Ichthyaria.
„ 20. Beania.

[1] See Busk, *Challenger Report*, p. xxii. See also genus 26, and p. 46, *ibid.*

Family VII. **Notamiidæ** (*Hincks*, not *Busk*).

Genus 21. Notamia.

Family VIII. **Gemellariadæ.**

Genus 22. Gemellaria.
,, 23. Didymia.
,, 24. Dimetopia.
Genus 25. Scruparia.
,, 26. Brettia.[1]
,, 27. Huxleya.

Family IX. **Farciminariadæ.**

Genus 28. Farciminaria.

Group B. FLUSTRINA.

Family X. **Flustridæ.**

Genus 29. Flustra.
,, 30. Carbasea.
Genus 31. Diachoris.

Family XI. **Membraniporidæ.**

Genus 32. Membranipora.
,, 33. Amphiblestrum.
,, 34. Biflustra.
Genus 35. Foveolaria.
,, 36. Pyripora.
,, 37 (?). Megapora[2] (*Hincks*)

Family XII. **Microporidæ.**

Genus 38. Micropora.
,, 39. Vincularia.
,, 40. Steganoporella.
Genus 41. Caleschara.
,, 42. Diplopora.
,, 43. Setosella.

Family XIII. **Electrinidæ.**

Genus 44. Electra.

Group C. ESCHARINA.

Family XIV. **Bifaxariadæ.**

Genus 45. Bifaxaria.
Genus 46. Calymmophora.

Family XV. **Salicornariadæ.**

Genus 47. Salicornaria.
Genus 48. Melicerita.

Family XVI. **Tubucellariadæ.**
(= Porinidæ, *Hincks*).

Genus 49. Tubucellaria.
Genus 50. Siphonicytara.

(?) Family XVI*a*.[3] **Porinidæ**, *Hincks*.

Genus 51 (?). Lagenipora.
Genus 52 (?). Celleporella.

(?) Family XVI*b*.[3] **Myriozoidæ**, *Hincks*.

Genus 53 (?) Rhynchopora, *H.*
Genus 54 (?) Schizotheca, *H.*

[1] See note, genus 5, *ante*.
[2] Not accounted for in the classification of Mr. Busk.
[3] *Ibid.*

Family XVII. **Onchoporidæ.**

Genus 55. Onchopora. Genus 56. Onchoporella.

Family XVIII. **Reteporidæ.**

Genus 57. Retepora.
„ 58. Reteporella.
Genus 59. Turritigera.

Family XIX. **Cribrilinidæ.**

Genus 60. Cribrilina. Genus 61. Membraniporella.

Family XX. **Microporellidæ.**

Genus 62. Flustramorpha. Genus 63. Microporella.

[Family XX*a*. Not accounted for by Mr. Busk.
Genus (?) Diporula, *Hincks*. Genus (?) Monoporella, *Hincks*.]

Family XXI. **Escharidæ.**

Genus 64. Eschara.
„ 65. Lepralia.
„ 66. Chorizopora.
„ 67. Porella.
„ 68. Escharoides.
„ 69. Smittia.
„ 70. Micronella.
„ 71. Aspidostoma.
„ 72. Schizoporella.
Genus 73. Gephyrophora.
„ 74. Myrizoum.
„ 75. Haswellia.
„ 76. Tessaradoma.
„ 77. Gemellipora.
„ 78 (?). Umbonula,[1] *Hincks*.
„ 78 (?). Phylactella,[1] *Hincks* (pt).
„ 79 (?). Palmicellaria,[1] *Hincks*.

Family XXII. **Adeoneæ.**

Genus 80. Adeona.
„ 81. Adeonella.
Genus 82. Reptadeonella.

Family XXIII. **Celleporidæ.**

Genus 83. Cellepora, *Fabricius*.

Family XXIV. **Selenariadæ.**

Genus 84. Cupularia. Genus 85. Lunularia.

It appears to me very improbable that Mr. Hincks will prefer the classification of Mr. Busk for that of his own. In his published papers, since the issue of the 'Challenger' Report, Mr. Hincks takes his own course, and it would be impertinent on my part to interfere with his arrangement. The numbered consecutive families and genera are those of the 'British Marine Polyzoa'; the interpolated families and genera (unnumbered) are the additions Mr. Hincks has been compelled to adopt in his study of the many foreign groups placed in his hands by collectors and others.

Sub-order. **CHEILOSTOMATA**, *Busk*.

Family I. **Æteidæ**, *Hincks*.

Genus I. Ætea, *Lamouroux* (1).

[1] Only partly accounted for in the classification of Mr. Busk

Family II. **Eucratiidæ**, *Hincks.*

Genus 2. Eucratea, *Lamx.*
„ 3. Gemellana, *Savig.*
„ 4. Scruparia, *Hincks.*
Genus 5. Huxleya, *Dyster* (27).
„ 6. Brettia, *Dyster* (5 & 26).
Genus. Rhabdozoum, *Hincks.*

Family III. **Cellulariidæ**, *Hincks.*

Genus 7. Cellularia, *Pallas* (9).
„ 8. Menipea, *Lamx.* (10).
Genus 9. Scrupocellaria, *Van Ben.* (12).
„ 10. Caberea, *Lamx.* (15).

Family IV. **Bicellariidæ**, *Hincks.*

Genus 11. Bicellaria, *Blainv.* (16).
„ 12. Bagula, *Oken* (17).

PART II. SYSTEMATIC ARRANGEMENT: GENERA AND SPECIES.

a. CHEILOSTOMATA, *Busk.*

In this part of my labours I have compiled, from all available sources accessible to me, the name of every described species of marine polyzoa. It may be that some of the Australian species of Macgillivray and others are omitted; if so, I shall regret it: but the excuse I offer is, Australian works generally were not at my disposal.

SUB-ORDER. **CHEILOSTOMATA**, *Busk.*

DIVISION I. STOLONATA, *Carus.*

Family I. **Æteidæ**, *Busk & Hincks.*

Genus. Ætea, *Lamx.*

Family II. **Eucratiidæ**, *Busk* (pt. *Hincks*).

Genus.	Eucratea, *Lamx.*	Genus.	Pasythea, *Lamx.*
,,	Hippothoa, *Lamx.*	,,	Brettia, *Dyster.*

Family III. **Chlidoniadæ**, *Busk.*

Genus. Chlidonia, *Savigny.*

('Challenger' Report, p. 1.)

Family I. Æteidæ

= ÆTEIDÆ, *Smitt, Hincks*
= SCRUPARIADÆ (pars), *Busk,* 'Brit. Mus. Cat.'
= STOLONATA (pars), *Carus.*

'Zoœcia tubular, with a subterminal membranous area; partly erect and free, partly decumbent and adherent; uniserial.'—*Challenger Report*, p. 1.

It may be well to note that the characters of this family as given above from Mr. Busk differ in some respects from those of Mr. Hincks ('Brit. Mar. Pol.' p. 1), but chiefly in the fact that Mr. Hincks includes in his diagnosis the following: 'Tentacular sheath terminal above in a circle of *setæ*, which are everted during the expansion of the polypide.'

It is thus seen that the Æteidæ connect together two groups—the *Ctenostomata* on the one hand, and the *Cheilostomata* on the other. Professor Smitt, Mr. Hincks, and Mr. A. W. Waters ('Bay of Naples Bry.,' 1879) have already remarked on the peculiar structural features of this group, which has been fully referred to in the Fifth Report on Fossil Polyzoa ('Brit. Assoc. Rep.', 1884).

As in my previous Reports, I shall furnish the characters of the families, and the genera only of recent polyzoa, as given either by Mr. Hincks or Mr. Busk, but it will be impossible to furnish details of the species.

Genus 1. Ætea, *Lamouroux*

= ANGUINARIA, *Lamk., Johnston, Busk,* 1849
= FALCARIA, *Oken*
= ÆTEA, *Busk* ('Brit. Mus. Cat.'), *Smitt, Hincks, Waters,* &c.

'Zoœcia calcareous, tubular, erect, with a membranous area on one side; distributed along a more or less adherent, creeping fibre, dilated at intervals; orifice terminal. Oœcia, none.'—*Brit. Mar. Polyzoa*, p. 3.

'Orifice semicircular, subterminal.'—*Busk*, 'Challenger' Report, p. 2.

1. Ætea anguina, *Linn.*, 'Brit. Mar. Poly.,' 'Challenger' Report.
2. ,, recta, *Hincks*, 'Brit. Mar. Poly.,' p. 6.
3. ,, truncata, *Lansb.*, 'Brit. Mar. Poly.,' p. 8.
4. ,, dilatata, *Busk*, 'Brit. Mus. Cat.,' pt. i.

5. *Ætea* ligulata, *Busk*, 'Brit. Mus. Cat.'
6. „ Americana, *D'Orb.*, 'Voy. dans l'Amér. Mérid.,' *D'Orb.*
7. „ argillacea, *Smitt.*

Mr. Hincks says (*op. cit.* p. 3): 'Seven species of *Ætea* have been described, of which three occur on our own coast.' In the 'Challenger' Report only one species is recorded as present in the material furnished to Mr. Busk (*Æ.* anguina, *Linn.*), and this was found at five of the stations: i. 36, 30 fathoms; ii. 161, 33 fathoms; iii. 135A, 75, 110 fathoms; iv. 304, 45 fathoms; v. 162, 38 to 85 fathoms.

Family II. **Eucrateadæ**, *Busk*

= EUCRATEIDÆ (pars), *Hincks*, 'Brit. Mar. Poly.,' p. 10
= SCRUPARIADÆ (pars), 'Brit. Mus. Cat.'

'Zoœcium erect and free or decumbent, more or less ordinate. Zoœcia uni- or bi-serial, or geminate, pyriform, with a subterminal oblique orifice, unarmed.'—*Busk*, 'Challenger Report on Polyzoa,' p. 2.

In the classification of British Marine Polyzoa, Mr. Hincks places in his family the following genera—*Eucratea*, *Gemellaria*, *Scruparia*, *Huxleya*, *Brettia*, *Dimetopia*, and *Calwellia*. As will be seen, only four genera are admitted by Mr. Busk, all of which are stolonate.

Genus 2. Eucratea, *Lamouroux*.

'Zoœcium usually with a creeping adherent base, erect branching. Zoœcia calcareous, rising one from another singly. Aperture oblique, terminal or subterminal. Orifice semicircular, with a straight lower border. Branches springing from the front of a zoœcium below the aperture.'—*Busk*, 'Challenger Report.' (Mr. Hincks's diagnosis is very similar to above.)

1. Eucratea chelata, *Linn.* (*Hincks*, 'British Marine Polyzoa,' p. 14, pl. i. fig. 3; pl. ii. figs. 4–8; pl. iii. figs. 9–11.
2. Eucratea chelata, *var. α.* repens, *Hincks*, pl. i. fig. 3.
3. „ „ „ *β.* gracilis, *Hincks.*

Both Mr. Busk and Mr. Hincks limit, as above, the genus *Eucratea*, and only one species is described as British, but Mr. Waters (Bay of Naples Bry.) describes the following species, remarking that he 'did not find *E. chelata* at Naples, but it is reported to have been found in the Mediterranean.'—*Ann. Mag. Nat. Hist.*, 1879, p. 117.

4. Eucratea ambigua, *D'Orb.* This species, which closely resembles *E. chelata*, is a native of South America.

Nos. 1 and 3, Mr. Hincks says, are very abundant in Australia. The species varies very much and 'in an early stage of growth is often decumbent. A few cells are repent and adnate, and from these the erect shoots arise, and the zoarium then assumes its normal condition' (Hincks, p. 15). *Eucratea chelata* is the only species described by Mr. Busk in his 'Challenger' Report, p. 3.

Genus 3. Hippothoa, *Lamouroux*

= CATENICELLA (pars), *Blainv.* = MOLLIA (pars), *Smitt.* ? TEREBRIPORA, *D'Orb.*

'Zoœcia calcareous, decumbent, adherent, usually distant and connected by tubular prolongations. Branches given off from the sides of the zoœcium. Orifice orbicular, sometimes produced and subtubular, with a sinus in the lower border.'—*Challenger Report*, p. 4.

On account of this last character—the 'sinus' in the lower border—Mr. Hincks ('British Marine Polyzoa,' p. 286) places *Hippothoa* in his family group MYRIOZOIDÆ in association with *Schizoporella*. Prof. Smitt 'disallows the genus and ranks its members with species which are supposed to possess similar zoœcia, irrespective of the habit of growth' (*op. cit.* p. 287).

1. Hippothoa divaricata, *Lamx.*, *Hincks*, 'British Marine Polyzoa,' p. 288.
   Hippothoa divaricata, *var.* α, conferta, *Hincks*, p. 288.
   " " " β, carinata, *Norman*, p. 289.
   " " " γ, Patagonica, *Busk.*
2. " expansa, *Dawson* (*Hincks*, p. 291).
3. " flagellum, *Manzoni* (*Hincks*, p. 293).
4. " distans, *Macgillivray* (*Hincks*, 'Polyzoa,' Queen Charlotte Island Annals, June 1883.

Only two species of *Hippothoa* are described by Mr. Busk in the 'Challenger' Report, *H. divaricata* and *H. flagellum*, Manzoni. The first at Station 135 in from 60 to 1,000 fathoms, and the other at Station 151, off Heard Island, in 75 fathoms. The *H. expansa*, Dawson, is a northern species, and the British species are cosmopolitan in their geographical distribution.

Genus 4. Pasythea, *Lamouroux*

= CELLARIA (sp.), *Solander*. = LIRIOZOA, *Lamk*. = EPICAULIDIUM, *Hincks*.

In the 'Ann. Mag. Nat. Hist.' Feb. 1881, p. 156, Mr. Hincks described as new under the generic and specific name of *Epicaulidium pulchrum* the *Cellaria tulipifera* of Solander. In his 'Challenger' Report (pp. 3 and 5) Mr. Busk draws attention to this species when describing a new form previously referred to by Smitt in his 'Floridian Bryozoa.' As Mr. Hincks's genus is replaced by the older name, I have thought it best to retain his generic description intact, especially so as Mr. Busk's diagnosis differs from that of Mr. Hincks.

'Zoarum calcareous, composed of a creeping base and erect stems, made up of internodes linked together at their extremities by corneous joints, on which the zoœcia are borne in companies. Zoœcia erect, clavate, with a small oblique subterminal orifice, several united together longitudinally, so as to form a cluster; the clusters opposite free, except at the base, where they are attached by corneous joints to the internodes.' —*Hincks, op. cit.* p. 157.

In a corrigendum, 'Ann. Mag. Nat. Hist.' Aug. 1881, p. 135, Mr. Hincks says that the above species was figured and described by Ellis (edited by Solander) under the name of *Cellaria tulipifera*; Lamouroux referred it to his genus *Pasythea*; De Blainville and Lamarck gave its generic rank—one as Tuliparia, *Blainv.*, the other as Liriozoa, *Lamk.*

1. Pasythea tulipifera, *Solander*, *Lamx.* = EPICAULIDIUM PULCHRUM, *Hincks*.
2. Pasythea eburnea, *Smitt* (Florid. Bryoz., *Busk*) = GEMELLIPORA EBURNEA, *Smitt*.

The only locality that I have the species from is Brazil. The slide came into my possession with others from the same locality, marked 'Membranipora, sp.', and it was only after Mr. Hincks's description was published that I was able to name it. Lamouroux's description of the form and also the locality given by him are as follows:—[1]

'Pasithea tulipifera. Articulations in the form of clubs; cells three in number, united on one pedicle' ('Corallina'), p. 67, pl. iii. fig. 7, A.

'American seas, principally on the Jamaica coast.' The other species described by Lamouroux is a hydrozoon.

The only other genus of the Eucratiidæ of Busk is the following. I have adopted the diagnosis of Hincks:—

Genus 5. Brettia, *Dyster.*

'Zoarium erect, corneous, branched, branches given of from the top of a cell a little to one side, and facing in the same direction as the cell. Zoœcia uniserial, elongate, subtubular; aperture, terminal or sub-terminal, large, with the oral valve at the upper extremity; margin armed with spines. Oœcia unknown.'—*Brit. Mar. Pol.* pp. 27, 28.

1. Brettia pellucida, *Dyster.* 'Brit. Mar. Pol.' p. 28 pl. iv. figs. 6, 7. 'Quart Jour. Micr. Soc.' vi., 1858, p. 260 pl. xxi. figs. 3–5.
2. Brettia tubæformis, *Hincks.* 'Brit. Mar. Pol.' p. 28 pl. ii. fig. 2, pl. v. fig. 1 = *B. pellucida*, Norman, 'Brit. Assoc. Rep.', 1866, p. 196, &c.

The first of these species was found by Mrs. Brett at Tenby; a minute fragment of the second was dredged in The Minch by Mr. Norman. These are very rare forms, but anyone, after carefully examining the plates in Mr. Hincks's work, can easily recognise the difference between the two species.

3. Brettia australis, *Busk.* 'Challenger Report,' p. 7 pl. xxxiv. fig. 3.
4. Brettia cornigera, *Busk.* 'Challenger Report,' p. 7, pl. xxxiv. fig. 6.

As Mr. Busk by some oversight places the genus Brettia in two families in the 'Challenger Report,' I have merely indicated its position further on by the number 26 ? so as to keep the synopsis and text intact, and preserve the suggestions even of the author.

As to the numbered families and genera given in the Report, with the exception of Notamiidæ and one or two genera, which will be pointed out in the text, the whole of the present arrangement is that of Mr. Busk. As, however, Mr. Hincks has instituted several genera, and one or two families which are not accounted for, accepted, or referred to in the 'Challenger Report,' I have thought it wise to include these in the several divisions, but *unnumbered.* Mr. Hincks, therefore, is responsible for their position in certain families. His names will be found in his own synopsis—the second—in the introductory part of the present Report.

[1] The work of Lamouroux, referred to above, is his *Corallina*, translated by a lady. Ed. 1824.

Family **Eucratiidæ**, *Hincks.*

Genus. Rhabdozoum, *Hincks.*

(‘Annals and Mag. Nat. Hist.’, vol. x. ser. 5, 1882.)

‘Zoarium erect phytoid, composed of numerous celluliferous shoots, held together by a ramified stem, made up of bundles of radical fibres, given off from the inferior portion of the shoots; celluliferous shoots consisting of a cylindrical bi- or tri-furcate stem, which gives origin to the radical fibres, and also to erect chitinous rods, on the summit of which are borne two or three similar stems, more or less dichotomously divided. Zoœcia pyriform, ranged in linear series round an imaginary axis, so as to form cylindrical stems; aperture moderately large, sub-terminal oblique. Avicularia not stipitate.’—*Hincks.*

Rhabdozoum Wilsoni, *Hincks, op. cit.* p. 162 pl. viii. fig. 4.
Locality : Port Phillip Head, Victoria, *Mr. Bracebridge Wilson.*

Family III. **Chlidoniadæ**, *Busk.*

‘Zoœcium composed of upright, free, segmented stems, springing from a stolonate network. From the segments, after the first bifurcation, arise lateral branches consisting of chains of zoœcia arising from the back near the summit. Zoœcia bicamerate; unarmed.’—*Busk,* ‘Chal. Rep.’ p. 8.

Genus 6. Chlidonia, *Savigny* (1811)

= Eucratea, *Aud.* (?) Vorticella, *Linn. & Esper.*
= Cothurnicella, *Wyv. Thomson.*

‘Free portion of the zoœcium composed of segmented tubular stems with distant short branches, each springing from one of the internodes of the stem, and giving off numerous uniserial chains of zoœcia, one rising from the back of another near the top, and all looking one way. Zoœcia gibbous, pyriform, or attenuated downwards. Orifice prominent or sub-tubular, lower lip entire, straight. The cavity of the zoœcium divided into two chambers, the hinder of which is much curved, and alone communicates with the orifice and lodges the polypide.’—*Busk,* ‘Chal. Rep.’ p. 8.

Chlidonia cordiera, *Aud.* (*Busk,* ‘Chal. Rep.’ pl. xxviii. fig. 11)
= Eucratea cordiera, *Aud.*, ‘Ægypta,’ pl. xiii. fig. 3
= Clidonia cordiera, *D'Orb.*, ‘Pal. Fr.’ p. 40
= Cothurnicella dædala, *Wyv. Thomson,* ‘Nat. Hist. Rev.’ vol. v. p. 146.

This species is very generally distributed. Mr. Busk gives it as occurring at only one station—No. 186. Mr. A. W. Waters describes it in his ‘Bay of Naples Bryozoa.’ Wyville Thomson's Australian form is from Port Phillip. It is also met with at the Canaries, ‘and I have specimens from the coast of Calvados, from Nice, Egypt (Sir Jos. Banks), and Tyre (*Miss Gatty*).’—*Busk,* ‘Chal. Rep.’ p. 9.

Division II. RADICELLATA.

Group A. Cellularina.

(*Busk*, 'Challenger Report,' p. 9.)

Family IV. **Catenariadæ**, *Busk*.

1850–2 = Catenariadæ (pars), *D'Orb.*
1852 = Catenicellidæ, *Busk.*
" = Scrupariadæ (pars), *Busk.*
" = Cellularieæ (pars), *Smitt.*

'Zoœcium radicate, segmented, internodes, except at a bifurcation, formed of a single zoœcium.'—*Busk*, 'Chal. Rep.' p. 9.

I. Catenicella, *Blainville.*
II. Catenaria, *Savigny.*

Genus 7. Catenicella, *Blainville.*

'Internodes usually unicellular, the zoœcia arising one from the upper and back part of another, by a corneous tube, all facing the same way and forming dichotomously divided branches of an erect phytoid zoœcium. The zoœcium at each bifurcation geminate; each zoœcium with two lateral, usually trilocular, processes (*alæ*). Oœcia either subglobose and terminal or immersed, and placed below the orifice of a zoœcium in front.'—*Busk*, 'Chal. Rep.' p. 10.

Mr. Busk describes the eight Challenger species in the collection, and figures only a portion of them. The first four belong to the section § *α. Fenestratæ*, the other to the section § *β. Vittatæ.* Since the publication of the 'Brit. Mus. Catalogue' (1852) many new species have been added to Mr. Busk's original list, and described and partially figured by Australian students. In the following list I have given the whole of the species known to me, and Mr. Waters has been able to add to the recent species many new fossil forms from the Australian tertiary beds, details of which will be found in my fifth 'Brit. Assoc. Rep. on Fossil Polyzoa,' 1884, Montreal.

1. Catenicella ventricosa, *Busk*, 'Brit. Mus. Cat.'
   " *var.* maculata, *Busk* (*op. cit.* pl. iii. figs. 4, 5).
2. " hastata, *Busk* (*op. cit.* pl. ii. figs. 3, 4).
3. " plagiostoma, *Busk* (*op. cit.* pl. v. figs. 1, 2).
4. " cribraria, *Busk* (*op. cit.* pl. v. figs. 3, 4); 'Chal. Rep.' p. 11, pl. i. fig. 6.
5. " sacculata, *Busk*, 'Chal. Rep.' pl. i. fig. 7.
6. " elegans, *Busk*=(?) *Eucratea Contei*, *Aud.*
   = *C. Savignyi*, *Blainv.*
   = *C. elegans*, *Busk*, 'Brit. Mus. Cat.' vol. i.; 'Chal. Rep.' pl. i. figs. 2, 3, 5.
7. " umbonata, *Busk*, 'Brit. Mus. Cat.'; (*var.*) 'Chal. Rep.' pl. i. fig. 1.
8. " pulchella, *Mapleston* ('Jour. Mic. Soc.', Victoria; 'Chal. Rep.' pl. i. fig. 4).
9. " lorica, *Busk*, 'Brit. Mus. Cat.'
10. " aurita, *Busk* " "
11. " amphora, *Busk* " "
12. " margaritacea, *Busk* " "

13. Catenicella forinosa, *Busk*, 'Brit. Mus. Cat.'
14. " perforata, *Busk* " "
15. " ringens, *Busk* " "
16. " cornuta " "
17. " gibbosa, *Busk* " "
18. " taurina, *Busk* " " (pl. xi.)
19. " carinata " "
20. " alata, *Wyv. Thoms.*, 'On New Gen. and Sp. of Polyzoa.'
21. " Harveyi, *W. Thoms.* " " "
22. " Dawsoni, *W. Thoms.* " " "
23. " castanea, *Wyv. Thoms.* " " "
24. " crystallina, *W. Thoms.* " " "
25. " Buskii, *Wyv. Thoms.* " " "
26. " geminata, *W. Thoms.*
27. " rufa, *Macgil.*
28. " concinna, *Macgil.*
29. " Wilsoni, *Macgil.*, 'On some New Sp. of *Catenicella*, &c.'
30. " gracilenta, *Macgil.*
31. " intermedia, *Macgil.*
32. " utriculus, *Macgil.*
33. " fusca, *Macgil.*
34. " Hannafordii, *Macgil.*
35. " insignis, *Macgil.*
36. " ponderosa, *Macgil.*
37. " (Catenicellopsis) deliculata, *Macgil.*

Mr. Hincks, in one of his papers—'Contributions towards a General History of Marine Polyzoa'—refers only to *Catenicella*, and says that though he has several species by him he would not describe or refer to them until the whole of the papers on the group were in his hands.

Genus 8. Catenaria, *Savigny*.

1811 = Catenaria (pars), *Savigny*, *D'Orb.*, 'Palæont.'
Eucratea (pars), *Aud.* (not Lamk., Blainv.)
1852. Alysidium (pars), *Busk*, 'Brit. Mus. Cat.'

'Zoarium erect or free, dichotomously branched; the Zoœcium at each bifurcation single. Zoœcia elongate, sub-tubular or trumpet shaped, without a frontal aperture. Mouth orbicular or semi-orbicular. Avicularia present or absent.'—*Challenger Report*, p. 14.

1. Catenaria Lafontii, *Aud.*, *Ægypta*, pl. xiii. fig. 2. A. W. Waters's 'Bay of Nap. Bryoz.' (Typical species of genus, *Busk.*)
= *Alysidium Lafontii*, *Busk*, 'Brit. Mus. Cat.'
2. " attenuata, *Busk*, 'Chal. Rep.' pl. ii. fig. 1.
3. " bicornis, *Busk*, 'Chal. Rep.' pl. ii. fig. 2.
4. " diaphana, *Busk*, 'Chal. Rep.' pl. ii. fig. 3
= *Scruparia diaphana*, *Busk*, 'Quart. Jour. Mic. Soc.,' vol. viii. p. 281, pl. xxxi. fig. 1.

Family V. **Cellulariadæ**, *Busk*

= Cellulariadæ, *Busk*, Crag Polyzoa; *Hincks*
= Cellulariadæ, 'Brit. Mus. Cat.'
= Cellularidæ (pars), *Johnston*
= Cellularicæ (pars), *Smitt.*

'Zoarium articulated, phytoid, erect, dichotomous, bi-, tri-, or multiserial. Zoœcia rising from a broad base, alternate, all facing the same way; a large oval membranous aperture. Avicularia, when present, sessile, and either lateral or anterior.'—*Challenger Report*, p. 15.

Mr. Busk, in the above report, divides the family into the following seven genera:—

1. Cellularia, *Pallas* (pars) § α, *aperta.*
   § β, *fornicata.*
2. Menipea, *Lamouroux*, Sections α and β.
3. Emma, *Gray.*
4. Scrupocellaria, *Van Beneden.*
5. Canda, *Lamouroux.*
6. Nellia, *Busk.*
7. Caberea, *Lamouroux*, Sections α and β.

Mr. Hincks, however, in his 'Brit. Mar. Polyzoa,' accepts the family Cellulariidæ, but his description differs in some few particulars from that of Mr. Busk.

'Zoœcia in two or more series closely united and ranged in the same plane; avicularia and vibracula, or avicularia only, almost universally present, sessile. Zoarium erect, dichotomously branched.'—*Hincks*, 'Brit. Mar. Pol.' p. 30.

Genera: Cellularia, *Pallas.*
Menipea, *Lamouroux.*
Scrupocellaria, *Van Beneden.*
Caberea, *Lamouroux.*

This important group has a very wide distribution. In his admirable introduction appended to the description of the family, Mr. Hincks (pp. 30–32) points out many peculiar modifications of the appendicular organs, and also of the radical fibres, 'by means of which the tufted zoaria are attached' to foreign bodies. There is still much to be learnt respecting these same radical fibres; and in speaking of the fibres, especially of *Scrupocellara reptens*, some curious modifications are pointed out. Mr. George Busk, in his paper on 'A Peculiar Form of Polyzoa closely allied to *Bugula*' ('Quart. Jour. Mic. Soc.' vol. xxi. new ser.), wherein he speaks of the 'radical and connecting tubes, like the avicularia and vibracula representing modified zooids.' This fact seems to be generally admitted, but still many minute particulars are pointed out by Mr. Busk in several species; and the student would do well to refer to this special paper, and also to the introduction of Mr. Hincks, previously referred to.

Genus 9. Cellularia, *Pallas.*

'Zoarum jointed. Zoœcia in two or three series, many in each internode, contiguous; dorsal surface perforated. Avicularia and vibracula usually wanting; occasionally an avicularium on a few of the cells of an internode.'—*Brit. Mar. Polyzoa*, p. 33.

1. Cellularia Peachi, *Busk*, 'Ann. Mag. Nat. Hist.' 2nd series, pl. vii. figs. 1–4. 'Brit. Mus. Cat.' i. 20. 'Brit. Mar. Polyz.' vol. i. p. 34, pl. v. figs. 2–5. Geographical range chiefly northern, British and American.

In the 'Challenger Report' Mr. Busk describes five new species of *Cellularia*, and remarks on the original specimen of *C. Peachii* as being entirely devoid of the cusp,[1] which Mr. Hincks speaks of as being present in the 'only British species'—*Cellularia Peachii*—that is known to him.

2. Cellularia cuspidata *Busk*, 'Brit. Mus. Cat.'
   = C. monotrypa, *Busk*, 'Voy. of Rattlesnake.'
3. „ crateriformis, *Busk*, 'Chal. Rep.' (pl. iii. fig. 1).
4. „ cirrata, *Busk*, 'Chal. Rep.' (pl. ii. fig. 4).
5. „ quadrata, *Busk*, 'Chal. Rep.' (pl. v. fig. 5).
6. „ biloba, *Busk*, 'Chal. Rep.' (pl. iii. fig. 2).
7. „ elongata, *Busk* (n. sp. ?), 'Chal. Rep.' pl. iii. fig. 3.
? „ ornata,[2] *Busk*, 'Brit. Mus. Cat.'
   = Menipea flabellata (?).

These species have a wide geographical range, and some of the specimens were dredged from great depths—2,650, 1,900, 1,425, and 900 fathoms—while others were derived from comparatively shallow depths—28 and 75 fathoms. The allied Australian species, *C. cuspidata* and *C. ornata*, 'closely resemble,' says Mr. Hincks, '*C. Peachii* in general character; but in *C. ornata* we meet with avicularia, . . . which are most sparingly developed and of a peculiar type. *C. Peachii* is totally destitute of appendicular organs.'—*Brit. Mar. Polyzoa*, p. 33.

Speaking of *C. cirrata*, *Busk*, Mr. Busk remarks 'that the general structure of the species is very peculiar, and together with other characters might perhaps justify its erection into a distinct genus.' There was only one specimen in the 'Challenger' collection, and this is both well described and well illustrated in the Report.

Genus 10. Menipea, *Lamouroux*

= Tricellaria (sp.) *Fleming*, *Blainville*, *Gray*
= Cellarina (pars) *Van Beneden*
= Cellularia (pars) *Johnst.*, *Smitt.*

'Zoœcia oblong, widest above, attenuated and often elongated downwards; imperforate behind, with a sessile lateral avicularium (often wanting), and usually one or two avicularia on the front of the cell. No vibracula. Zoarium jointed.'—*Brit. Mar. Polyzoa*, p. 36.

Mr. Busk divides the species of *Menipea* into two sections, § α. *Fornicatæ* and β. *Apertæ*. In a note ('Chal. Rep.' p. 15) on *Fornicatæ*, Mr. Busk says, 'A better term would have been "scutatæ," but as Prof. Smitt has introduced the term "*fornix*" for what I had originally named "operculum," now generally employed for the oral valve, I have adopted his term.'

1. Menipea ternata, *Ell. & Sol.* (*Hincks*, p. 38, pl. vi. figs. 1–4).
   „ „ British, chiefly northern.
   „ „ *Var.* gracilis, *Smitt*, Arctic form.
   = Cellularia ternata (forma gracilis), *Smitt.*
2. „ gracilis, *Busk*, 'Polyzoa N. Polar Exped.' (No. 14.)
   In a note, p. 40, Mr. Hincks says, 'I have received

[1] There is no cusp in the Shetland specimens given to me by Miss E. C. Jelly; originally from C. W. Peach's dredgings, 1864.
[2] See *Menipea flabellum*, Lamouroux.

from Mr. Peach two or three minute fragments of a *Menipea* from Shetland, in which the form of the cells is that of the *gracilis* variety. They also show a larger number in the internode than is characteristic of the normal *M. ternata*.' But on account of their imperfect condition Mr. Hincks was unable to say whether they should be referred to the variety, or to one of the closely related forms, *M. arctica*, or to

3. Menipea Smittii, *Norman*
   = Cellularia ternata (forma duplex), *Smitt.*
4. „ Jeffreysii, *Norman* (*Hincks*, pl. ix. figs. 1, 2), 'Quart. Jour. Mic. Soc.' 1868.
5. „ compacta, *Hincks*, 'Ann. Mag. N. Hist.' Dec. 1882.
   Var. triplex, *Hincks* „ „ „
6. „ cyathus, *Wyv. Thoms.*
7. „ arctica, *Busk.*
   Given as *var.* M. ternata, *var.* gracilis, *Smitt.*

In the 'Challenger Report' nine species are described by Mr. Busk, five of which are new.

§ *a. Fornicatæ.*

8. Menipea benemunita *Busk*, 'Chal. Rep.' pl. iv. fig. 4.
9. „ aculeata, *D'Orb.*, 'Chal. Rep.' pl. iv. fig. 2
   = Tricellaria aculeata, *D'Orb.*
   = Ternicellaria aculeata, *D'Orb.*
   = ? Menipea feugensis, *Busk*, 'Brit. Mus. Cat.'
10. „ clausa, *Busk*, 'Chal. Rep.' pl. iv. fig. 5.
11. „ flabellum, *Lamx.*, 'Chal. Rep.' p. 21
    = Cellularia ornata, *Busk*, 'Brit. Mus. Cat.'
    = ? Menipea flabellum, *Lamx.*
    Cellaria flabellum, *Ell. & Sol.*
12. „ flagellifera, *Busk*, 'Chal. Rep.' pl. iv. fig. 1.
13. „ Marionensis, *Busk*, 'Chal. Rep.' pl. iv. fig. 3; pl. xiv. fig. 9.
14. „ triseriata, *Busk*, 'Chal. Rep.' p. 21, 'Brit. Mus. Cat.'
15. „ cirrata, *Lamx.*, 'Chal. Rep.' p. 22
    = Cellaria cirrata, *Ell. & Sol.*
    = Cellaria crispa, *Pallas.*
    Tubularia cirrata, *Esper.*, *Seba.*
16. „ pateriformis, *Busk*, 'Chal. Rep.' pl. iv. fig. 4.
17. „ compacta, *Hincks*, form triplex, *Hincks.*
    Pol. Queen Charlotte Islands, 'Ann. Mag. Nat. Hist.' Dec. 1882.
18. „ marginata, *Hincks*, Polyzoa of Victoria, Australia, 'Ann. Mag. Nat. Hist.' p. 227, pl. ix. fig. 5. *Locality*: Port Phillip Head.
19. „ Buskii, *Wyv. Thoms.*

Genus 11. Emma, *Gray*

= Emma, *Gray*, *Busk*, 'Voy. of Rattlesnake,' 'Brit. Mus. Cat.' p. 27; *T. W. Hutton.*

Menipea (sp.) *Wyville Thomson; Hincks.*

'Zoœcia in conjoined pairs or triplets in each internode (not opposite), much expanded above and contracted below. Upper part of front occupied by a wide sub-triangular bordered area, partially filled in by a granular lamina, and with a sub-orbicular membranous aperture. A lateral sessile avicularium placed below the level of the aperture.'—*Busk*, 'Chal. Rep.' p. 22.

In his 'British Marine Polyzoa' Mr. Hincks disallows the genus *Emma,* and he places the name among the synomyms of the genus *Menipea.* Notwithstanding this, Mr. Busk restores the only species in the 'Challenger' material to its old place, as—

Emma crystallina, *Gray*, 'Chal. Rep.' p. 23
= E. crystallina, *Busk*, 'Brit. Mus. Cat.'

Genus 12. Scrupocellaria, *Van Beneden*

= Canda, sp., *Busk* = Bicellaria, sp., *Blainv.*
Cellularia, *Waters*, 'Bay of Nap. Bry.'

'Zoarium jointed. Zoœcia numerous in each internode, rhomboid; aperture with or without an operculum; a sessile avicularium placed laterally at the upper and outer angle, and a vibraculum in a bend or sinus on the lower part of the dorsal surface; frequently an avicularium on the front of the cell.'—*Hincks*, 'Brit. Mar. Pol.' p. 43.

As species of *Scrupocellaria* range backward in time from the present seas to the Miocene of Austria-Hungarian deposits, it is not surprising that many synonyms must necessarily fall under a few of the well-marked specific forms. Mr. Hincks has been exceptionally careful in his diagnosis of the five British forms, as the student will be pleased to find when working up the forms which are widely and generally distributed round our coast. Mr. Waters extends the area of three British species in his 'Bry. Bay of Naples.'

α. Without an operculum.

1. Scrupocellaria scruposa, *Hincks*, pl. vii. figs. 8–10.
2. „ elliptica, *Reuss*, *Hincks*, pl. vi. figs. 5, 6
= S. inermis, *Norman.*

β. With an operculum.

3. „ scabra, *Van Ben.*, *Hincks*, pl. vi. figs. 7–11.
4. „ scrupea, *Busk*, *Hincks*, p. vii. figs. 11–14.
5. „ reptans, *Linn.*, *Hincks*, pl. vii. figs. 1–7.

These are the whole of the British species given by Mr. Hincks. Mr. A. W. Waters, in his 'Bay of Naples Bryozoa,' gives as *Cellularia S. reptans*, *S. scruposa*, and *S. scrupea.*

In his 'Challenger Report,' Mr. Busk describes five species:—

6. Scrupocellaria Macandrei, *Busk*, 'Chal. Rep.' pl. xi. fig. 4
= S. Macandrei, *Busk*, 'Brit. Mus. Cat.'
7. „ ciliata, *Aud.*, 'Chal. Rep.' pl. xi. fig. 5
= S. diadema, *Busk*, 'Brit. Mus. Cat.'
8. „ ornithorhyncus, *Wyv. Thoms.* 'Chal. Rep.' pl. vi. fig. 6
= ? S. clypeata, *Haswell.*

9. Scrupocellaria pilosa, *Aud.*, 'Chal. Rep.' pl. xi. fig. 7
= Crisia pilosa, *Savig.*, 'Egypt.'
10. „ securifera, *Busk*, 'Chal. Rep.' pl. xi. fig. 2.

Mr. Hincks, in his various contributions, adds to the number of species which he describes or figures in the papers referred to.

11. Scrupocellaria varians, *Hincks*, Polyzoa of Queen Char. Is., 'Ann. Mag. Nat. Hist.,' Dec. 1882, pl. xix., figs. 1–10.
12. „ brevisetis, *Hincks*, *op. cit.* No figure. Bears some resemblance to S. scrupea.
13. „ obtecta, *Haswell*, *Hincks*, Contributions, &c. 'Ann. Mag. Nat. Hist.,' March 1883, p. 193, pl. vi. fig. 1.
14. „ cervicornis, *Busk* (*op. cit.* p. 193. No. fig.).
15. „ diadema, *Busk*, 'Brit. Mus. Cat.,' *Hincks*, 'Ann. Mag. Nat. Hist.,' May 1884. Polyzoa of India.

In his 'British Mus. Catalogue' Mr. Busk gives the following additional species:—

16. Scrupocellaria cyclostoma, *Busk*.
17. „ ferox, *Busk*.
18. „ Delilei, *Busk*.
19. „ Maderensis, *Busk*.
20. „ inermis, *Busk*.

The radical fibres of the different species of *Scrupocellaria* are a very interesting study, but more on account of their position and character than as means of distinguishing the difference between species by means of them alone. In *S. scruposa* they are slender and smooth, and given off at the lower part of the zoarium. In *S. scabra* they are long and slender, and scattered over the whole of the zoarium. In *S. reptans* the radical fibres are either simple and given off as anastomosing fibrils forming a netted disc, or toothed. Two forms are present in the different species. In one they are simply tubes, in another they are, as Mr. Hincks says, 'veritable grapnels.' In this form 'the fibre is covered for about two-thirds of its length with sharp, recurved, hook-like processes, and is converted into an admirable prehensile organ, which, when plunged into the soft sarcode of the sponge or other yielding substance, holds the polyzoon, like an anchor, to its place.' Ellis noticed these hook-like processes, and Couch, in his 'Cornish Fauna,' also noticed and recorded several peculiarities in the modes of attachment to other polyzoa. These hooked fibres are not, however, found on recent species only. In some of the Carboniferous *Fenestella*, hooked spines, though considerably more robust than any which now exist, are prominent features in the zoarium, and in all probability their purposes were the same in the economy of the species. Mr. Busk and Mr. Hincks's comments are well worth special study by the student.

Genus 13. Canda, *Lamouroux*

= Canda, *Lamx.*, *Blainv.* (pars), *D'Orb.*, and *Busk*, 'Brit. Mus. Cat.'
Scrupocellaria (pars), *Hincks*.

'Branches biserial, dichotomous, connected by transverse chitinous tubes, inserted at both ends into a vibracularium. No lateral avicularia, and the anterior avicularia when present placed on a special median tract, or on the summit of the oœcia. A vibracularium lodged in a sinus behind; flagellum short, flattened, not toothed. With or without a pedunculate fornix.'—*Busk*, 'Chal. Rep.' p. 25.

1. Canda arachnoides, *Lamx.*, 'Chal. Rep.' p. 25
   = Cellaria filifera, *Lamk.*, vol. ii. p. 177.
2. „ simplex, *Busk*, 'Chal. Rep.' p. 26, pl. xiv. fig. 8.
3. „ retiformis, *Smitt*, 'Florid. Bry.' (See following remarks.)

The Canda arachnoides, *Lamx.*, is abundant and fine in the Australian seas; but as the C. simplex is an Atlantic species, Mr. Busk's remarks on the form are very appropriate. 'In the "Challenger" collection this form is represented by only one or two minute fragments, in pretty good condition, but which would have been insufficient for its determination had I not been in possession of specimens of obviously the same form from the Gulf of Mexico. . . . It is a remarkable circumstance that a second species of Canda also occurs in the Gulf of Mexico, which has been described by Prof. Smitt (Florid. Bry., pt. I. p. 16, pl. v. figs. 43–46), under the not very well chosen name of *Caberea retiformis*.'—*Busk*, 'Chal. Rep.' p. 26.

Lamouroux's figure of C. arachnoides is good, and his description is well worth giving. 'Frondescent, fan-shaped, and dichotomous polypidom. Branches united by small lateral and horizontal fibres. Cells alternate, united, placed on only one surface, and not projecting.' 'Flex. Coral,' p. 57, pl. ii. figs. 6, *a b c d*.

Locality: On the rocks of Tamor.

Genus 14. Nellia, *Busk*

= Salicornaria (pars.), *Bk.*, 'Voyage of Rattlesnake,' vol. i. p. 367
= Nellia, *Bk.*, 'Brit. Mus. Cat.' vol. i. p. 18. *Smitt.*

'Zoarium articulated, internodes short, quadrangular. Zoœcia quadriserial, front flat or convex at bottom. The greater part of the front occupied by a large aperture; border prominent, especially above, smooth and thick. Orifice quite at the summit. Oœcia absent.'—*Chal. Rep.* p. 26.

1. Nellia oculata, *Busk*, 'Chal. Rep.' p. 27
   = N. oculata, *Bk.*, 'Brit. Mus. Cat.'
   = N. oculata, *Smitt*, 'Florid. Bry.'
   = N. oculata, *Macgil.*, 'Nat. Hist. Vict.'
2. „ simplex, *Busk*, 'Chal. Rep.' pl. v. fig. 6; and 'Brit. Mus. Cat.' p. 19.

Genus 15. Caberea, *Lamx.*

= Selbia, *Gray*; Flabellaria, *Gray*; Canda, *D'Orb.*

'Zoarium not articulated. Zoœcia not articulated, sub-quadrangular or ovate, with a very large aperture. Sessile avicularia on the side and front of the cells, the lateral avicularium minute. Vibracular cells very large, placed in two rows, stretching obliquely downwards across the

back of the zoœcia, which they almost cover, to the median line, notched above and traversed through a great portion of their length by a shallow groove. Setæ usually toothed on one side.'—*Hincks*, 'Brit. M. Pol.' p. 57.

1. Caberea Ellisii, *Flem.* (*Hincks*, p. 59, pl. viii. figs. 6–8). Arctic species, ranging to the more northerly portions of our coast, and to Labrador and Maine.
2. ,, Boryi, *Audouin* (*Hincks*, p. 61, pl. viii. figs. 9–11). 'Almost cosmopolitan.' Egypt, Adriatic, New Zealand, Australia: S. Patagonia; Strait of Magellan, &c.
3. ,, Hookeri, *Busk*, 'Brit. Mus. Cat.' vol. i. p. 39. This Mr. Hincks places as synonymous with C. Ellisii, *Flem.*, and the C. zelanica, *Busk* ('Voy. Rattlesnake,' vol. i. p. 378), as the same as C. Boryi, *Aud.*

In speaking of the vibracula, &c. of C. Boryi, Mr. Hincks says (p. 58, *op. cit.*): 'In this species there not only are the individual appendages highly developed, but the whole company of them attached to a colony are brought into combined and harmonious action. It must be left to future observation to determine the precise structural conditions on which these remarkable movements depend; but they certainly seem to imply the *existence*[1] *of a nervous system, distinct from that of the individual polypides, by which the vibracular zooides are controlled and brought into relation.*'

4. Caberea grandis, *Hincks*, Contributions, &c., 'Ann. Mag. Nat. Hist.' July 1881, pl. iii. figs. 4 *a*, *b*, *c*. Off Curtis Is. (*Capt. Warren*).

Mr. Busk in his 'Challenger Report' describes six species of *Caberea*, three of which are new.

§ *α*. fornicatæ.

5. Caberea rostrata, *Busk*, 'Chal. Rep.' pl. xxxii. fig. 4.
6. ,, crassemarginata, *Busk*, 'Chal. Rep.' pl. xi. fig. 1.
7. ,, Darwinii, *Busk*, 'Chal. Rep.' pl. xxxii. fig. 6
   = C. patagonica, *Busk*, 'Brit. Mus. Cat.'
   = C. zelanica, *Busk*, 'Voy. of Rattlesnake.'
8. ,, rudis, *Busk*, 'Chal. Rep.' p. 30, and 'Brit. Mus. Cat.'
9. ,, minima, *Busk*, 'Chal. Rep.' pl. xxxii. fig. 5.

§ *β*. apertæ.

10. ,, lata, *Busk*, 'Chal. Rep.' p. 30, pl. xi. fig. 3
    = 'Brit. Mus. Cat.'; 'Voy. of Rattlesnake.'
11. ,, Lyallii, *Busk*, 'Chal. Rep.' p. 29
    = Selbia zelanica, *Gray*.

This name is substituted by Mr. Busk for Gray's New Zealand species (*Selbia Zelanica*), after having fully satisfied himself that the species is quite distinct from '*Caberea boryi*, under which appellation, both I and other authors have confounded two or three quite distinct species.'—*Busk*, 'Chal. Rep.' p. 29.

[1] Italics mine.

Family VI. Bicellaridæ.

In the family group bearing the above name Mr. Busk ('Crag Polyzoa,' p. 15) placed three genera—*Bicellaria*, *Halophila*, and *Bugula*. Mr. Hincks, in the 'Brit. Mar. Polyzoa,' retains the family name which includes the following genera :—

Genus Bicellaria, *Blainville* ; Genus Beania, *Johnston* ;
„ Bugula, *Oken* ;

remarking that the first and last of the three are linked together by the genus *Bugula* and the genus *Diachoris*. . . . *D. Spinigera*, Macgil, . . . in a young state . . . is hardly distinguishable from a *Beania*, pp. 65, 66. In his paper (Contributions towards a General History of the Marine Polyzoa, 'Ann. Mag. Nat. Hist.', February 1881, p. 157), Mr. Hincks includes in the family, Diachoris, *Busk*.

In the 'Challenger Report,' Mr. Busk adheres to his original family name, but he adds to the number of the genera by including *Kinetoskias*, Koren and Dan., and Ichthyaria, *Busk*.

'Zoœcia, rather loosely united in two or more series, or disjunct; obconic, or boat shaped, the aperture usually occupying a large proportion of the front.—Avicularia, when present, capitate; pedunculate, and jointed. Zoarium not articulated ; erect and phytoid, or composed of a number of cells connected by tubular processes.'—*Hincks*, p. 64.

In the 'Challenger Report,' Mr. Busk describes the character of the family somewhat different from the above :—

Zoœcia turbinate or sub-turbinate, biserial, the two series more or less disjunct. Aperture large, directed obliquely upwards. Avicularia, when present, usually pedunculate and capitate or trumpet shaped ; rarely sessile, not articulated, and placed either on the anterior or posterior aspects. P. 32.

Genus 16. Bicellaria, *Blainville*.

'Zoarium erect, phytoid. Zoœcia turbinate or in the form of a cornucopia, loosely united, more or less free above ; aperture looking more or less upward, directed obliquely inwards below ; inferior portion of the cells sub-tubular, usually much produced. Avicularia, when present, jointed and capitate. No vibracula.'—*Hincks*, p. 66.

1. Bicellaria ciliata, *Linn.* *Hincks*, p. 68, pl. viii. figs. 1–5.
   British form, but it has a rather restricted geographical range, including North America (*Kirchenpauer*), and a variety in South Africa (*Hincks*).
2. „ Alderi Busk, *Hincks*, p. 70, pl. ix. figs. 3–7
   = B. unispinosa, *Sars*.
   Both the Brit. localities and also the geographical range of this species are restricted.
3. „ gracilis, *Busk*, 'Brit. Mus. Cat.'
4. „ grandis, „ *ibid.*
5. „ tuba, „ *ibid.* p. 42, pl. xxxi.

Australian forms. In *B. tuba* there is a fixed avicularium borne at the top of a tall spinous process ; consequently, as Mr. Hincks remarks, this species forms an exception to the latter part of the diagnosis of the genus given above. 'Avicularia,' &c.

In the 'Challenger Report,' Mr. Busk describes seven species, five of which are new.

1. Bicellaria navicularis, *Busk*, 'Chal. Rep.' pl. vii. fig. 2.
2. „ pectogemma, *Goldstein*, 'Chal. Rep.' pl. vii. fig. 1. Goldst. Pro. Roy. Soc. Vict. 1881.
3. „ infundibulata, *Busk*, 'Chal. Rep.' pl. vi. fig. 2.
4. „ bella, *Busk*, 'Chal. Rep.' pl. vi. fig. 4.
5. „ moluccensis, *Busk*, 'Chal. Rep.' pl. vi. fig. 4.
6. „ glabra, *Hincks*, 'Chal. Rep.' pl. vi. fig. 1 = Stirparia glabra, *Hincks*, 'Ann. Mag. Nat. Hist.' ser. v. vol. xi. p. 195.
7. „ macilenta, *Busk*, 'Chal. Rep.' pl. xxxii. fig. 1.

In certain remarks ('Chal. Rep.' p. 36) Mr. Busk justifies his adoption of these specific names, to the whole of which I direct the attention of the student, as without the plates and diagnoses it would be useless to quote extracts.

Genus 17. Bugula, *Oken*.

This genus has a number of synonyms, for which see Hincks, 'Brit. Mar. Polyzoa'; but one peculiar form, not given by Mr. Hincks, is the subject of a rather elaborate paper by Mr. Busk which will be referred to further on.

1. Bugula avicularia, *Linn.; Hincks*, p. 75, pl. x. figs. 1–4 = Ornithopora, id. *D'Orb.; Pal.; Fr.*
2. „ turbinata, *Alder; Hincks*, p. 715, pl. x. figs. 5–8.
3. „ flabellata, *J. V. Thompson; Hincks*, p. 80, pl. xi. figs. 1–3 = Ornithoporina avicularia, *D'Orb.*
4. „ calathus, *Norman; Hincks*, p. 82, pl. xi. figs. 4–6.
5. „ plumosa, *Pallas; Hincks*, p. 84, pl. xii. figs. 1–5.
6. „ gracilis, *Busk*, 'Quart. Jour. Mic. Soc.' vi. p. 125. *Var.* uncinata, *Hincks*, p. 86, pl. xv. figs. 1–4; pl. xii. figs. 6, 7.
7. „ purpurotincta, *Norman; Hincks*, p. 89, pl. xii. figs. 8–12.
8. „ Murrayana, *Johnst.; Hincks*, p. 92, pl. xiv. figs. 2–9.

These are the whole of the British forms given by Mr. Hincks, some of which have a very wide range around our coast; and the geographical range is also very varied. In Mr. Waters's 'Bry. Bay of Naples' he records as Mediterranean forms—

1. Bugula avicularia, *Pallas* = B. turbinata, *Hincks*.
3. = B. flabellata, *J. V. Thompson*.
5.(?) „ fastigiata = B. plumosa, *Pallas*. In S. O. Ridley's paper on the Polyzoa of the 'Alert' Expedition ('Ann. Mag. Nat. Hist.' 1881), the author quotes—
9. B. Murrayana, *var.* fruticosa, *Packard*, as one of the forms of the Arctic circle. Mr. Busk (Polyzoa of the North Polar Expedition, 'Linn. Soc. Jour. Zoology,' vol. xv.) gives the two forms as distinct.
8. „ Murrayana, *Johnst.* (sp.) (*op. cit.* p. 233) = Flabellaria spiralis, *Gray*
„ = Avicella multispina, *Van Ben.*

9. Bugula fruticosa, *Packard* (sp.) (*op. cit.* p. 233)
= B. Murrayana, *var.* fruticosa, *Hincks*
= Menipea fruticosa, *Packard.*
But in a note (p. 233 *op. cit.*) Mr. Busk says: 'Since the above was in type I am more inclined to agree with those who regard *B. fruticosa* as a variety of *B. Murrayana.*'
10. „ uniserialis, *Hincks,* 'Annals,' May 1884, p. 367, pl. xiii. fig. 8. *Loc.*: Victoria, Australia.

At a meeting of the Scientific Society of Christiana, March 1867, D. C. Daniellsen gave an account of two new forms of Polyzoa, which he called *Kinetoskias.* In his notes on a form ('Quart. Jour. Mic. Soc.' vol. xxi. new series) Mr. Busk has made several references to a form closely allied to Bugula (*Kinetoskias, Kor. & Dan.*). Many interesting particulars are given by Mr. Busk in this paper, which the student will do well to refer to. In this Report I will give the results arrived at by the author.

1867. Bugula umbella, *Smitt.*
1873. Naresia cyathus, *Sir C. W. Thomson.*
Bugula Smittii, *Sars.*

Speaking of the genus *Naresia*, Sir C. W. Thomson, several specimens of which are in the Challenger collection—one procured from a depth of 2,650 fathoms—Mr. Busk says: 'The different forms constitute certainly three—and, as I am inclined to think, four—distinct and well-characterised species; but they all agree in certain very peculiar characters, which would seem to be almost, if not quite, sufficient to render the group composed of them of generic value, or at any rate to rank as a distinct sub-genus of *Bugula.* To this genus or sub-genus the appellation bestowed upon it by Koren and Daniellsen obviously has priority over *Naresia.*'

1. Bugula (Kinetoskias) Smittii, *Dan.*
= Kinetoskias Smittii, *Kor. & Dan.*
= Bugula Smittii, *Sars.*
2. „ (Kinetoskias) aborescens, *Dan.*
= K. arborescens, *Kor. & Dan.*
= Bugula umbella, *Smitt.*
3. „ (Kinetoskias) cyathus, *Sir C. W. Thomson*
= Naresia cyathus, *Sir C. W. Thomson*
= K. Smittii, *Kor. & Dan.*
4. „ (Kinetoskias) pocillum, *Busk,* 'Quart. Jour. Mic. Soc.' (*op. cit.*)

In addition to descriptions of all these species Mr. Busk draws attention to the peculiar cell structure, and also gives an elaborate account of the radical tubes or fibres of the same.

In the 'Challenger Report' Mr. Busk modifies the definition of *Bugula* so as to admit the new forms described by him in it.

Zoœcia bi- or multi-serial, closely contiguous and united, arising in continuous series each from the back of the subjacent one. Aperture partial or entire. Avicularia, when present, always on the anterior aspect of the zoœcia.—*Busk*, p. 37.

§ α. Species in which the branches of one part of zoarium are bi-serial, and in another tri- and quadri-serial.

§ β. Species in which the zoœcia are much attenuated downwards. Avicularia supported on long flexible pedicels.

§ γ. Species in which the zoœcia are usually oblong, and little or not at all attenuated downwards. Avicularia shortly pedunculate. Examples: *Bugula* (Bicellaria), *flabellata*, *turbinata*, *avicularia*, *plumosa.*

§ δ. Species in which the zoœcia are wholly unarmed. Examples: *Bugula* (Halophila), *Johnstoniæ*, *Gray.*

§ α. Abyssal forms (?).

1. Bugula versicolor, *Busk*, 'Chal. Rep.' pl. iii. fig. 4.
450 to 350 fathoms.
2. „ leontodon, *Busk*, 'Chal. Rep.' pl. x. fig. 5.
1,525 fathoms.
3. „ sinuosa, *Busk*, 'Chal. Rep.' pl. x. fig. 2.
80 to 150 fathoms.
4. „ mirabilis, *Busk*, 'Chal. Rep.' pl. x. fig. 1.
2,400 fathoms.

§ β.

5. „ reticulata, *Busk*, 'Chal. Rep.' pl. viii. fig. 3.
1,600, 600, 2,160, and 1,325 fathoms.
5.* „ *Var. a*, unicornis, *Busk*, 'Chal. Rep.' pl. ix. fig. 2.
2,500, 1,850, 2,175 fathoms.
6. „ bicornis, *Busk*, 'Chal. Rep.' pl. ix. fig. 1.
1,950 fathoms.

§ γ.

7. „ margaritifera, *Busk*, 'Chal. Rep.' pl. viii. fig. 4.
1,900 to 2,200 fathoms.
8. „ neritina, *Linn.* (sp.) 'Chal. Rep.' p. 42.
9. „ longissima, *Busk*, 'Chal. Rep.' p. xxxi. fig. 7.

Having utilised a previous paper by Mr. Busk on *Kinetoskias*, it only remains for me to give the arrangement of the species in the 'Challenger Report.'

Kinetoskias Smittii, *Kor.* & *Dan.*, 'Chal. Rep.' p. 43. Only referred to in Report.
1. „ cyathus, *Wyv. Thomson*, 'Chal. Rep.' pl. viii. fig. 1 = Naresia, *id. Wyv. Thomson.*
2. „ pocillum, *Busk*, 'Chal. Rep.' pl. viii. fig. 2.

Additional remarks on this genus will be given further on when speaking of a new genus and species instituted by Mr. Hincks.

Genus 19. Ichthyaria, *Busk.*

'Zoarium continuous, branched; branches irregularly dichotomous or forked, biserial, zoœcia facing in one direction; the two series very loosely connected. Zoœcia ventricose, rounded, fork entirely calcified.'—*Challenger Report*, p. 46.

Ichthyaria oculata, *Busk*, 'Chal. Rep.' pl. xiii. fig. 7.

These are the whole of the genera admitted by Mr. Busk in his

'Challenger Report.' Mr. Hincks, however, believing that *Beania* belongs to the *Bicellaria*, rather than to any other group, I place it here out of deference to the author. It is not referred to by Mr. Busk, consequently it does not appear in his synopsis. I have therefore numbered it (20 ?).

Genus (20 ?). Beania, *Johnston.*

'Zoarium sub-corneous or calcareous, erect or decumbent. Zoœcia sessile, erect, scattered, united one to the other by a slender tube, originating from the dorsal surface or from the side near the base; aperture occupying the entire front, the margin furnished with hollow spinous processes arching over the opening; mouth terminal. Oœcia and avicularia wanting.'—*Hincks*, p. 95.

1. Beania mirabilis, *Johnston; Hincks*, p. 96, figs. 8–10, pl. iv. This is the only British species of the genus, and Hincks gives several localities besides the following distribution of this form :—
   Scandinavia; Adriatic; Roscoff.
2. „ australis, *Busk*, 'Brit. Mus. Cat.'
   Patagonia.
3. „ Swainsoni, *Hutton.* (See *Hincks*, 'Brit. Mar. Pol.' p. 96.)
   An erect phytoid form, New Zealand.
4. „ admiranda, *Packard* (*Hincks, op. cit.* p. 96).
   Labrador.

As members of the Bicellariadæ, Mr. Hincks has instituted the two following genera for species found in his Australian collection. It is only fair both to Mr. Busk and to Mr. Hincks to say that in the 'Challenger' collection Mr. Busk has already figured (pl. vi. fig. 1) the Stirparia glabra of Hincks as *Bicellaria stylites*; but as Mr. Hincks's name was published before the issue of the Report the name is changed to that of *B. glabra*, Hincks ('Chal. Rep.'); and in a note Mr. Busk adds, 'Since the above was in type Mr. Hincks has described apparently the same form under the name of *Stirparia glabra*, and gives a full account of the peculiar structure on the zoarium and its stem from better material than those at my command.' I think that Mr. Busk will see that the peculiarities of this remarkable form demand its separation from *Bicellaria* proper, but not from the family in which Mr. Hincks has placed it.

Genus Stirparia, *Goldstein.*

'Zoarium, consisting of erect segmented stems, chitinous or calcareous, and of celluliferous branches, which originate in more or less fabellate tufts close to the summit of the segments. Zoœcia of the normal Bicellarian type, turbinate, somewhat free above; aperture looking more or less upward, turned obliquely inwards, inferior portion of the cells sub-tubular. Avicularia articulated.'—*Hincks*, 'Ann. Mag. Nat. Hist.' vol. xi., ser. 5, p. 195, 1883.

1. Stirparia annulata, *Maplestone*, 'Jour. Micr. Soc. Victoria,' 1870 (type).
2. „ glabra, *Hincks*, 'Ann. Mag. Nat. Hist.' vol. xi. 1883, p. 196, pl. vi. fig. 2
   = Bicellaria glabra, *Busk*, 'Chal. Rep.'

Genus Stolonella, *Hincks.*

Loc.: Geraldton, Western Australia (*Miss Gore*).

The generic description of Mr. Goldstein is revised so that the kindred species, *S. glabra*, may be included.

The following is another peculiar Australian species, for which the generic name is instituted by the author, 'Ann. Mag. Nat. Hist.,' vol. xi. p. 197, 1883.

Zoarium consisting of a creeping stolon, and zoœcia distributed upon it. Stolon chitinous, free in itself, but attached at intervals by adhesive branching discs, which originate from short stolonic offsets, jointed, more or less branched. Zoœcia erect, scattered, always developed close to a joint, attached to the stolon by the pointed lower extremity of the dorsal surface, sub-calcareous, boat-shaped, aperture occupying the whole front, closed in by flattened spinous ribs united together; orifice terminal.

Stolonella clausa, *Hincks* (*op. cit.* p. 198, pl. vii. fig. 6).

Loc.: Creeping over *Fucus*, Geraldton, West Australia (*Miss Gore*).

Mr. Hincks remarks (p. 197, *op. cit.*) 'that the true stoloniferous character of this form seems to call for its separation from *Beania* as represented by our British *B. mirabilis*.'

Family VII. **Notamiidæ**

= Gemellariidæ, *Busk* (part).

'Zoœcia in pairs, each pair arising by tubular prolongations from the pair next but one below it; at each bifurcation a new series of cells intercalated into the branches.'—*Hincks*, 'Brit. Mar. Pol.,' p. 98.

Mr. Hincks says, 'the remarkable structure of the zoarium of *Notamia bursaria* entitles it to stand as the type of a separate family, . . . and the Australian genus *Calwellia* resembles *Notamia* to some extent in the structure of the zoarium.'

In the 'Trans. Microp. Soc. Lond.,' vol. ii. 1849, Mr. Busk gave a somewhat exhaustive account of *Notamia* and its peculiar structural details. In the synopsis which prefaces the description of the Crag Polyzoa, Mr. Busk places *Notamia* as the first genus of his family Gemellariidæ. Only one species described :—

Genus 21. Notamia, *Fleming.*

1. Notamia bursaria, *Linn.*, *Hincks*, p. 100, pl. v. figs. 1–5
= (?) Calwellia bicornis, *W. Thomson.*

Family VIII. **Gemellariidæ,** *Busk*

= Encratiidæ (pars), *Hincks*, 'Brit. Mar. Polyzoa.'

'Zoarium sub-membranaceous, flexible, continuous. Zoœcia opposite, in pairs, unarmed.'—*Busk*, 'Chal. Rep.,' p. 46.

Excepting the genus *Natamia*, which Mr. Hincks takes as the type of his family Notamiidæ, the family Gemellariidæ, *Busk*, includes the same genera as originally arranged under it in the 'Brit. Mus. Cat.,' to which others are added in the 'Challenger Report'; consequently as now arranged the whole appears to be a very natural group.

Genus. Gemellaria, *Savigny.*
„ Didymia, *Busk.*

Genus Dimetopia, *Busk*, 'Brit. Mus. Cat.'
„ Scruparia (pars), *Hincks* (not *Smitt*).
„ ? Brettia, *Dyster*.
„ Huxleya, *Dyster*.

But only species of two genera are described in the 'Challenger Report.'

Genus 22. Gemellaria, *Savigny*.

'Zoarium erect, phytoid. Zoœcia joined back to back; the cells composing the pairs rising one from the top of the other, all the pairs facing the same way. Aperture large, on the front of the cell, slightly oblique. Branches given off from the sides of the cells, close to the upper extremity. No vibracula or avicularia. Oœcia none.'—*Brit. Mar. Polyzoa*, pp. 17, 18.

1. Gemellaria loricata, *Linn.*, Sys. Ed. 10–815; *Hincks*, 'Brit. Mar. Pol.,' p. 18, pl. iii. figs. 1–4.

2 (?). „ Willisii, *Dawson*, coasts of Nova Scotia. This latter form differs from *G. loricata* 'in its narrower and less inflated cells and longer apertures, and in its more dense habit of growth.' I believe with Mr. Hincks that the species 'presents only the character of a variety,' and he places it as a synonym of *G. loricata*.

Genus 23. Didymia, *Busk*.

Didymia, *Busk*, 'Voy. of Rattlesnake,' 'Brit. Mus. Cat.'

'Zoœcia joined side by side, all facing the same way. At a bifurcation each zoœcium of the primary pair giving off a secondary pair. Frontal area almost entirely membranous. Oœcia on a third intermediate zoœcium at a bifurcation.'—*Busk*, 'Chal. Rep.' p. 47.

Didymia simplex, *Busk*, 'Chal. Rep.' p. 47. *Id.*, 'Brit. Mus. Cat.,' *Macgil.*, *Wyville Thom.*

Genus 24. Dimetopia, *Busk*.

'Brit. Mus. Cat.,' 'Voy. of Rattlesnake,' *Macgil.*

'Zoœcia in pairs, apposed back to back; infundibuliform, with a large orifice, each pair facing in a direction at right angles to that of the next; at a bifurcation each of the separate zoœcia gives of a secondary pair.'—*Busk*, 'Chal. Rep.'

1. Dimetopia cornuta, *Busk*, 'Chal. Rep.' p. 47.
2. „ spicata, *Busk*.

Genus 25. Scruparia, *Hincks*.

'Zoarium erect. Branches given off from the back of a cell, and facing in the opposite direction. Zoœcia sub-calcareous, rising one from the other, so as to form a single series, or placed back to back. Aperture small, unarmed, slightly oblique, terminal. Ovicelligerous cells small, and imperfectly developed, placed back to back with the ordinary cells. Oœcia terminal. No avicularia or vibracula.'—*Brit. Mar. Pol.* p. 21.

Scruparia clavata, *Hincks*, 'Brit. Mar. Pol.' p. 24.
'Quart. Jour. Mic. Soc.' pl. xvii. figs. 5–8.

Genus (26 ?). Brettia, *Dyster.*

By some oversight Mr. Busk refers this genus to two different families. See genus 5 of the present Report.

Genus 27. Huxleya, *Dyster.*

'Quart. Jour. Mic. Soc.' vi. p. 260, 1858; *Hincks*, 'Brit. Mar. Polyzoa,' p. 26.

'Zoarium corneous or sub-calcareous, dichotomously branched, the branches given off from the top or side of a cell, and facing in the same direction. Zoœcia uniserial; orifice small, sub-terminal, unarmed.'—*Brit. Mar. Polyzoa*, p. 26.

Huxleya fragilis, *Dyster, Hincks*, 'Brit. Mar. Polyzoa,' pl. ii. fig. 1.

Mr. Hincks has altered the generic character of Dyster. The original description represents the cells as biserial; hence in placing the genus in the *Gemellaridæ* it appears to be out of place. Mr. Hincks places *Huxleya* in his family EUCRATIIDÆ in company with *Brettia.*

Family IX. **Farciminariadæ.**

Id., *Busk*, 'Brit. Mus. Cat.' and 'Challenger Report' only.

'Zoarium sub-membranaceous or corneous, continuous, erect, ramose, radicate. Zoœcia quadri- or multi-serial, disposed round an imaginary axis, and forming cylindrical or prismatic branches.'—*Challenger Rep.*, p. 48.

Only one genus is placed in this family by Mr. Busk in the 'Challenger Report,' but in his remarks on *Farciminaria* he suggests the necessity of establishing two species formerly described as *Farciminaria* ('Quart. Jour. Mic. Soc.' new ser., vol. i. p. 155) in a genus by themselves as *Verrucularia*,[1] V. Suhr,

= Farciminaria, *id.*, *Busk.*
Port Phillip (Australia), *Kirchenpauer.*

Regarded by V. Suhr as a fucus = Verrucularia dichotoma, *V. Suhr*, 'Flora,' 1834, p. 725, tab. i. fig. 9.

Verrucularia Binderi, *Harvey* (?), 'Quart. Jour. Mic. Soc.' vol. i. p. 156, pl. xxxv. figs. 2, 2*a*.

In his original description of the above, Mr. Busk makes the following remarks (*loc. cit.* p. 156):—

'It seems doubtful whether these two species should be referred to our genus *Farciminaria*, but we have thought it better, provisionally at any rate, to place them in it. Should it be thought advisable to separate them from *F. aculeata*, there appears to be no reason against the adoption of V. Suhr's name, *Verrucularia*, notwithstanding his having placed the genus among the Fuci.'

Genus 28. Farciminaria, *Busk.*

Id., *Busk*, 'Brit. Mus. Cat.,' *Kirchenpauer* (pars)? 'Challenger Report,' p. 48.

Zoarium furcate or dichotomous; the angle of each bifurcation

[1] Verrucularia dichotoma (*V. Suhr*), 'Quart. Jour. Mic. Soc.' vol. i. p. 155, pl. xxxv. figs. 1, 1*a*.

occupied by a hollow membranous expansion (modified zoœcium?). Zoœcia oblong, elongated, almost entirely membranous in front, which is depressed or flat, with an acute angular border. Avicularia, when present, sessile or sub-immersed, placed at the bottom in front. Mouth close to the summit, more or less protruded, the oral valve projecting. Oœcia cucullate, superior.

Eight species are described in the 'Challenger Report,' all of which are new, and as these peculiar forms are found generally in deep seas I have given the depth in which each form was taken, the same as in some of the species of the genus *Bugula* in a former part of the present Report.

1. Farciminaria atlantica, *Busk*, 'Chal. Rep.' pl. xxxi. fig. 6. 450–390 fathoms.
2. „ cribraria, *Busk*, 'Chal. Rep.' pl. v. fig. 2. 1,900 fathoms.
3. „ magna, *Busk*, 'Chal. Rep.' pl. v. fig. 1. 1,675 and 2,650 fathoms.
3*a*. „ *Var.* armata, *Busk*, 'Chal. Rep.' pl. xxxi. fig. 1. 1,900 fathoms.
4. „ Brasiliensis, *Busk*, 'Chal. Rep.' pl. xxxi. fig. 2. 400 fathoms.
5. „ Pacifica, *Busk*, 'Chal. Rep.' pl. xxxi. fig. 4. 2,300 fathoms.
6. „ gracilis, *Busk*, 'Chal. Rep.' pl. v. fig. 3. 1,675 fathoms, 32 to 400 fathoms.
7. „ delicatissima, *Busk*, 'Chal. Rep.' pl. xxxi. fig. 5. 1,900, 2,175, 2,400, 1,850, and 1,950 fathoms.
8. „ hexagona, *Busk*, 'Chal. Rep.' pl. xiv. fig. 10, pl. xxxi. fig. 3. 140 to 310, 825, and 1,425 fathoms.

In these *Farciminariæ* very peculiar characters are noted by the author, and the student of both the recent and fossil species of Polyzoa would do well to refer to them.

If we except the two species already placed in the genus *Verrucularia* (V. Suhr) the only species described in the 'Brit. Mus. Cat.' by Mr. Busk is the following, which will make nine species in all:—

9. Farciminaria aculeata, *Busk*, 'Brit. Mus. Cat.'
10 (?). „ uncinata, *Hincks*, 'Ann. Mag. Nat. Hist.' Oct. 1884, p. 277, pl. viii. fig. 2.

This is the Australian species originally described by Mr. Busk, but the *F. atlantica*, *Busk*, No. 1 of the above list, 'strongly resembles' *F. aculeata*. Especially so 'in the aculeate marginal spines being simple, and not furcate, as they mostly are in the Australian species, on the smoothness and comparatively smaller size of oœcium, and in the presence on very many of the zoœcia of a large avicularium.' [1]

[1] Busk, *Chal. Rep.* p. 49.

Group β. FLUSTRINA.

Family X. **Flustridæ**

= Flustridæ, *Busk*, 'Brit. Mus. Cat.'; *Gray* (pars)
= Flustridæ (pars), *D'Orb.*; *Hincks*, 'Brit. Mar. Polyzoa.'
Smitt, 'Krit. Fortech. Scandinav. B.'
= Escharidæ (pars), *Johnst.*, 'Brit. Zoophites.'

Mr Busk in the 'Challenger Report' arranges the genera of this family differently from that of Mr. Hincks in his 'British Marine Polyzoa.'

Genus Flustra, *Linn.*
,, Carbasea, *Gray.*
,, Diachoris, *Busk*, 'Challenger Report.'

Mr. Hincks does not separate the species of *Carbasea*, but includes the whole in the genus *Flustra*, and *Diachoris* he places in a different family.

The following is Mr. Hincks's arrangement in his 'British Marine Polyzoa':—

Family **Flustridæ**

= Escharidæ (pt.), *Johnston*, 'Brit. Zoophites,' *D'Orb.*, 'Pal. Fr.'
= Flustridæ (pt.), *Busk*; Flustridæ, *Smitt.*

'Zoarium corneous and flexible, expanded, foliaceous, erect. Zoœcia contiguous, multiserial. Avicularia usually of a very simple type.'—*Hincks*, p. 113.

Genus Flustra, *Linnæus*

(for F. papyracea)
= Chartella, *Gray*; Carbasea, *Gray*; Semiflustra (sp.), *D'Orbigny.*

'Zoarium erect, frondose. Zoœcia disposed in a single layer, or in two layers, united by the dorsal surfaces, more or less quadrangular or linguiform, with a raised margin, the aperture occupying the whole or a considerable portion of the front of the cell, and closed in by a membranous covering. Oœcia immersed.'—*Hincks*, p. 114.

a. Zoarium in two layers.

1. Flustra foliacea, *Linnæus*, *Hincks*, p. 115, pl. xiv. and xvi.
2. ,, papyracea, *Ell. & Sol.*, *Hincks*, p. 118, pl. xvi. fig. 2.
3. ,, securifrons, *Pallas*, *Hincks*, p. 120, pl. xvi. fig. 3.
,, *Var.* papyracea, *Dalyell.*
4. ,, Barleeii, *Busk*, 'Quart. Jour. Mic. Soc.' 1860, p. 123, pl. xxv. fig. 4; *Hincks*, p. 122, pl. v. figs. 6–8.

b. Zoœcia in a single layer.

5. Flustra Carbasea, *Ell. & Sol.*, *Hincks*, p. 123, pls. xiv. and xvi.
= Carbasea papyracea, *Gray*
= Carbasea, paperea, *Busk*, *Alder*
= Semiflustra carbusea, *D'Orb.*

These are the only British species recorded, described, and figured by Mr. Hincks.

There is something very peculiar about the zoœcia of *F. Barleeii.* The cells are large and rectangular, with an unarmed margin, avicularia oblique. Ovicells in the dry specimens immersed. This is caused by the top wall of the zoœcium, to which the ovicell is attached, being lower than the side walls which support the roofing. The localities of the species are Shetland, in about 50 fathoms; entrance to the Bömmelfjord, in 106 fathoms (*Kirchenpauer*).

In his 'Contributions' Mr. Hincks describes other species of *Flustra.*

6. Flustra dentigera, *Hincks,* Australia, 'Annals,' Feb. 1882, pl. v. fig. 7.
7. " reticulum, *Hincks,* "
   Flustra dissimilis, *Busk,* Bass's Straits.
8. " solida, *Stimpson.* See Note on Hincks's Pol. Barrent's Sea, 'Annals,' Oct. 1880, p. 282, pl. xv. figs. 2, 3.

The following species is a peculiarly northern form, but Mr. Hincks gives it in his Report in the 'Poly. Queen Charlotte Is.'

9. Flustra membranaceo-truncata, *Smitt.*
   Virago Sound, North Sea, and Arctic Seas common.

In the 'Challenger Report' Mr. Busk describes four species of *Flustra,* three of which are new; seven species of *Carbasea,* two of which are new; and five species of *Diachoris.*

§ A. Zoœcia contiguous.

§§ *a.* Utrinque porosæ, *Linn.*

Genus 29. Flustra, *Linn.*

'Zoœcia disposed in two inseparable layers (except when decurrent).' —*Busk,* 'Chal. Rep.' p. 53.

1. Flustra crassa, *Busk,* 'Chal. Rep.' pl. xvi. fig. 6.
   Remarkable, says Mr. Busk, for its thick, almost fleshy consistence.
   The species is only recorded from one station, 149*a.* Kerguelen Island, 28 fath.
2. " denticulata, *Busk,* 'Chal Rep.' pl. xxxii. fig. 2
   = F. denticulata, *var.* inermis, *Busk,* 'Brit. Mus. Cat.'
3. " biseriata, *Busk,* 'Chal. Rep.' pl. xvi. fig. 1.
4. " membraniporides, *Busk,* 'Chal. Rep.' p. xxxii. fig. 7.

Genus 30. Carbasea, *Gray.*

'Zoœcia in a single layer. Front either completely or partially membranous.'—*Chal. Rep.,* p. 55.

1. Carbasea ovoidea, *Busk,* 'Chal. Rep.' pl. xvi. fig. 3, and 'Brit. Mus. Cat.' p. 52, &c.
2. " dissimilis, *Bk.,* 'Chal. Rep.' p. 55
   = C. dissimilis, *Bk.,* 'Brit. Mus. Cat.' p. 51
   = Flustra carbasea, *var. β, Lamk.*
3. " elegans, *Bk.,* 'Chal. Rep.' pl. xvi. fig. 5, and 'Brit. Mus. Cat.' p. 53.
4. " pedunculata, *Bk.,* 'Chal. Rep.' pl. xvi. fig. 4.
5. " Moseleyi, *Bk.,* 'Chal. Rep.' pl, xxxiii. fig. 4. Specimen showing the polypides.

6. Carbasea piciformis, *Busk*, 'Chal. Rep.' p. 57, and 'Brit. Mus. Cat.' p. 50.
7. „ cribriformis, *Busk*, 'Chal. Rep.' pl. xxxiv. fig. 8, and 'Brit. Mus. Cat.' p. 51
= Retepora cornea, *Bk.*, 'Voy. of Rattlesnake,' vol. i. p. 380.

Genus 31. Diachoris, *Busk.*

'Zoarium flexuose, spreading, loosely adnate, or sub-erect and free. Zoœcia flustrine, completely distinct, each connected, with six or more, by tubular processes.'—*Chal. Rep.*, p. 59
= Diachoris, *Busk*, 'Voy. of Rattles.'; 'Brit. Mus. Cat.'; *Heller*; *Macgil.*; *Hutton*
= Mollia (*pars*) *Smitt.* Eschara (*pars*) *Moll.*

1. Diachoris Magellanica, *Bk.*, 'Chal. Rep.' p. 59
= D. Magellanica, *Bk.*, 'Brit. Mus. Cat.'
= D. Buskei, *Heller*, 'Adriatic.'
1[1]. „ „ *Var. a*, distans, *Bk.*, 'Chal. Rep.' pl. xvi. fig. 2.
2. „ crotali, *Bk.*, 'Chal. Rep.' p. 59, and 'Brit. Mus. Cat.'; 'Voy. of Rattles.'; *Macgil.*; 'Nat. Hist. Vic.' Decad. V. p. 32.
3. „ costata, *Bk.*, 'Chal. Rep.' pl. xxxiv. fig. 4.
4. „ inermis, *Bk.*, 'Chal. Rep.' p. 60, and 'Brit. Mus. Cat.' p. 54.
5. „ hirtissima, *Heller*, 'Chal. Rep.' p. 61
= D. hirtissima, *Heller*, 'Adriatic,' p. 94
= Chaunosia, *id.*, *Bk.*, 'Quart. Jour. Mic. Soc.' vol. vii. pl. xxxvi. figs. 12–16.

In addition to this very full record of the genus *Diachoris* from the 'Challenger Report' of Mr. Busk, I think it only fair on my part to give as full a list as possible from all other sources, not only of the genus *Diachoris*, but of *Flustra* and *Carbusea* also.

No true *Diachoris* has yet been recorded as occurring in British Seas, but Mr. Waters in his 'Bay of Nap. Bry.' (*op. cit.* p. 120, Feb. 1879) records three species from this locality.

1. Diachoris patellaria, *Moll.*, 'Ann. Mag. Nat. Hist.' Feb. 1879, pl. x.
= Eschara, *id.*, *Moll.*; Mollia, *id.*, *Smitt*
= Diachoris simplex, *Heller*, 'Bry. Adr.'
2. „ „ *Var.* multijuncta, *Waters*
= Eschara depressa, *Moll.*
3. „ Magellanica, *Busk*, 'Mar. Pol.' p. 54
= D. Buskei, *Heller.*
Mr. Hincks, 'Contrib. to Ann. Mag. Nat. Hist.' Feb. 1881, p. 157, describes a new form from New Zealand.
4. „ bilaminata, *Hincks*, pl. viii. figs. 7, 7a, and the zoarium is composed of two layers of cells placed back to back; the connecting tubes six in number, and very short.
Mr. Waters says the definition of *Diachoris* would

[1] In a note Mr. Busk says that the *D. distans* described by Mr. Hincks from South Africa is quite distinct from the above.

require altering to admit his *D. patellaria*, var. *multijuncta*, . . . and he says that *Diachoris* can only be looked upon as a provisional one; an opinion with which Mr. Hincks 'quite agrees.' But Mr. Hincks says in addition to this that 'the affinity between *Diachoris* and *Beania* and *Bugula* is of the closest kind.' 'Ann. Mag. Nat. Hist.' Feb. 1881, p. 157. The following are the described species:—

5. Diachoris crotali, *Busk*, Bass's Straits.
,, Magellanica, *Busk* = D. Buskei, *Heller*, Straits of Magellan; New Zealand.
,, inermis, *Busk*, same localities.
,, costata, *Busk*, Kerguelen Island.
,, spinigera, *Macgil.*, Australia.
,, hirtissima, *Heller*, Adriatic; Cape of Good Hope = Chaunosia, *id.*, *Busk*.
,, Buskiana, *Hutton*, New Zealand.

In another of his 'Contributions' Mr. Hincks describes other species of this genus ('Ann. Mag. Nat. Hist.' Aug. 1881, pp. 132–134).

,, distans, *Hincks*, *op. cit.* p. 132, pl. v. figs. 4–6, South Africa. Resembles the D. spinigera, *Macgil.*
,, intermedia, *Hincks*, *op. cit.* p. 133, Tasmania.
,, hirtissima, *Heller*.
form. robusta, *Hincks*, *op. cit.* p. 133, pl. v. figs. 9, 9a.

The *Chaunosia fragilis* described by Mr. Ridley (Proc. Zool. Soc. 1881, p. 45), from the Straits of Magellan, 'approaches still more nearly to *Beania*; its polypide, however, is said to be furnished with a gizzard, and it may possibly be entitled to generic rank.'—*Hincks*, *op. cit.* p. 133.

In another paper, 'Polyzoa of New Zealand and Australia,' contributions 'Ann. Mag. Nat. Hist.' March 1885, Mr. Hincks gives a very full account of Diachoris, and describes two new species.

Diachoris elongata, *Hincks*, pl. ix. fig. 1, Napier, New Zealand.
,, quadricornuta, *Hincks*, pl. ix. fig. 2, Australia.

Very many of these Australian forms of Polyzoa, though described by Mr. Hincks, we owe to the laborious scrutiny of Miss E. C. Jelly, whose specimens Mr. Hincks so justly and so continuously acknowledges; Some specimens we owe to Miss Gatty; but for the enthusiastic dredgings of Mr. Bracebridge Wilson, the Port Phillip Head (Victoria) Polyzoa would have been a loss to science.

Mr. Hincks[1] speaking of the genus *Diachoris*, as originally defined by Busk, says that it 'must be regarded as a purely artificial division. But most of the forms which have been ranked under the name present well-marked characters . . . and are properly associated as a natural group. They have the cell of *Bugula* and are furnished with the capitate and articulated avicularium so characteristic of that genus. . . . And probably the natural relationships would be best represented by ranking the true forms of *Diachoris* as a subsection of the genus *Bugula*.' The

[1] *Ann. Mag. Nat. Hist.*, March 1885, p. 246.

disjunct cells is a character which would seem to have but little real significance, for Mr. Hincks says, 'it seems as an occasional condition in species the cells of which are normally continuous, and we have an instance of this in the disjunct form of the well-known *Microporella Malusii.*'

Microporella Malusii, *Audouin*, form disjuncta, *Hincks*, 'Ann. Mag. Nat. Hist.' vol. xv. 5th series, March 1885, p. 249.

Family XI. **Membraniporiidæ**, *Busk*,

'Challenger Report,' p. 61
= Membraniporidæ (pars), 'Brit. Mus. Cat.,' *Smitt* and *Hincks*
= Microporidæ (sp.), *Smitt* and *Hincks*.
For other synonyms, *see* Report.

'Zoarium membranous, membranaceo-calcareous, encrusting and adnate, or erect and free, foliaceous or lobed, then bilaminar or polygono-cylindrical. Zoœcia depressed in front with a raised border, the area filled in by a chitinous membrane, beneath which may be an entire or partial calcified lamina.'—*Chal. Rep.* p. 61.

As this very important group is differently arranged by Mr. Busk in the above Report than by Mr. Hincks in his 'British Marine Polyzoa,' and in his papers, 'Contributions to a General History of the Marine Polyzoa,' I must be pardoned if in this and the following parts of my Report I give as full a digest as possible of the views of the different authors; especially so as Mr. Hincks—and others who adopted his classification—had made considerable advances previous to the publication of the 'Challenger Report.'

The following genera are contained in the 'Challenger' collection, which Mr. Busk arranges as below :—

1. Membranipora, *Blainville*. 2 sections, α and β.
2. Amphiblestrum, *Gray*.
3. Biflustra, *D'Orbigny*.
4. Foveolaria, *Busk*. New genera.
5. Pyripora, *D'Orbigny*. No species in the 'Challenger' collection.

Genus 32. Membranipora, *Blainville*

= Membranipora (pars), *Blainv.*, *Johnst.*, *Auc.*
= Annulipora, Conopeum, Cellepora, Amphiblestrum (sp.), *Gray*
= Cellipora (pars), *D'Orb.*, *Hag.* = Marginaria, *Rœmer.*

'Zoarium encrusting, adnate, calcareous or sub-calcareous; zoœcia quincuncially or serially disposed in transverse rows or irregularly; no internal calcareous lamina; operculum incomplete.'—*Op. cit.* p. 62.

In a note Mr. Busk says that the term *incomplete* is applied to an operculum whose lower border is membranous and more or less ill defined.

The genus *Membranipora*, like the old genus *Lepralia*, has become by the addition of many new species almost unmanageable. Even so as restricted as above. Mr. Busk says the 'genus *Membranipora* includes so many species that it becomes advisable to subdivide it into sections. I am acquainted, either actually or by published descriptions, with between thirty and forty living species, to which no doubt copious additions remain to be made.'

§ *α*. Simplices (no marginal spines).

1. Membranipora albida (?), *Hincks*, pl. xv. fig. 4.
? M. albida, *Hincks*. (*See* following No. 33.)
2. „ crassimarginata, *Hincks*. (No. 30.)
Var. *α*, erecta, *Busk*, 'Chal. Rep.' pl. xiv. fig. 3.
„ *β*, incrustaris, *Busk*, 'Chal. Rep.' pl. xv., fig. 5.
= ? Biflustra Lacroixii, *Smitt*, 'Florid Bryozoa,' pl. ii. p. iv. figs. 85–88.

§ *β*. Spinosæ.

3. Membranipora spinosa, *D'Orb*. 'Voy. en Amér. Mérid.' pl. viii. fig. 1
= M. ciliata, *Macgil*. 'Nat. Hist. Vict.' Decade III.
= M. spinosa, *Busk*, 'Chal. Rep.' p. 64.
4. „ galeata, *Busk*, 'Chal. Rep.' 64; and 'Brit. Mus. Cat.'
Var. *a*, furcata, *Busk*, 'Chal. Rep.' p. 64.
„ *β*, multifida, *Busk*, „ „
„ *γ*, erecta, *Busk*, „ p. 65.

Genus 33. Amphiblestrum, *Gray*.

Type of Genus, *Membranipora Flemingii*.

(See following list, No. 21 to 26.)

'A partial internal calcareous lamina. Aperture more or less trifoliate or obovate.'—*Chal. Rep*. p. 65.

1. Amphiblestrum imbricatum, *Busk*, 'Chal. Rep.' pl. xv. fig. 3.
2. „ cristatum, *Busk*, 'Chal. Rep.' pl. xv. fig. 1.
3. „ papillatum, *Busk*, 'Chal. Rep.' pl. xxxiii. fig. 1.
4. „ cervicorne, *Busk*, 'Chal. Rep.' p. 66
= Membranipora, *id*. 'Brit. Mus. Cat.' p. 60.
5. „ umbonatum, *Busk*, 'Chal. Rep.' p. 66
= Membranipora, *id*. 'Brit. Mus. Cat.' p. 57.
6. „ capense, *Busk*, 'Chal. Rep.' pl. xxiii. fig. 3.

This last species is very doubtfully placed with *Amphiblestrum*.

Genus 34. Biflustra, *D'Orbigny*

= Biflustra, *D'Orb*.; *Busk*, 'Crag Polyzoa,' p. 71. *Manzoni*, *Stolickza*, *Macgil*. (sp.), *Smitt* (pars)
= Flustrellaria (pars), *D'Orb*.

Zoarium dimorphous, encrusting or decurrent, and unilaminar, or foliaceous erect, and bilaminar, readily fissile in all directions. Zoœcia in alternate series, longitudinal or transverse. Zoœcia flustrine, quadrangular or hexagonal (?), with a denticulate lamina at bottom.

Biflustra Savartii, *Audouin*, 'Chal. Rep.' pl. xiv. fig. 2
= Flustra, *id*. *Aud*., 'Ægypte' pl. x. fig. 10
= Membranipora, *id*. *D'Orb*., 'Palæon.'; *Busk*, 'Crag Polyzoa,' p. 31.
= „ corrugata, *Blainv*.
= Biflustra Savartii, *Smitt*, 'Florid. Bry.'

Mr. Busk says of this species that there may be some doubt whether this is really *Flustra Savartii* of Savigny and of the Crag.

Genus 35. Foveolaria, *Busk* ('Chal. Rep.' p. 68).

Zoarium erect, branched and cylindrical, or foliaceous and bilaminar. Front of zoœcia with a thick granular border very deeply imbedded in a pit formed by the thickening of the general ectocyst. A sessile avicularium immediately below or in front of the lower border of the pit.

1. Foveolaria elliptica, *Busk*, 'Chal. Rep.' pl. xxiiii. fig. 5.
2. „ orbicularis, *Busk*, 'Chal. Rep.' pl. xxiii. fig. 4.
3. „ tubigera, *Busk*, 'Chal. Rep.' pl. xiv. fig. 4.
4. „ falcifera, *Busk*, 'Chal. Rep.' pl. xv. fig. 6.

Genus 36. Pyripora, *D'Orbigny.*

Type of genus, *Hippothoa* (Membranipora) *catenularia*, Jameson.

Now that I have given a full list of the whole of the species, in the several divisions of the Membraniporidæ, *Busk* ('Challenger Report'), I do not think that it will be considered at all out of place if I furnish, to the best of my ability, a full list of described forms, details of which will be found in the works of Mr. Busk ('Brit. Mus. Cat.'), Mr. Waters ('Bay of Nap. Bryozoa' and 'Papers on Australian Bryozoa'), Mr. Hincks ('Brit. Mar. Polyzoa'), and Contributions, &c. 'Ann. Mag. Nat. Hist.' Many of the species—thanks to the kindness of Miss E. C. Jelly—are in my cabinet; and even now, from what I know of undescribed species, many remain yet with manuscript names, which will ultimately find their proper place in our lists. For obvious reasons I include no species in the list which have not been fully described.

Family. **Membraniporidæ**, *Hincks.*

'Zoarium calcareous or membrano-calcareous, incrusting. Zoœcia forming an irregular continuous expansion, or in linear series, with raised margins, and more or less membranaceous in front.' — *Brit. Mar. Polyzoa*, p. 126.

Genus. Membranipora, *Blainv.*

'Zoarium incrusting. Zoœcia quincuncial or irregularly disposed, occasionally in linear series; margins raised; front depressed, wholly or in part membranaceous.'—*Brit. Mar. Polyzoa*, p. 128.

a. *With a membranous front wall.*

British Species.

1. Membranipora Lacroixii, *Aud.* (*op. cit.* p. 129, pl. xvii. figs. 5–8).
2. „ Monostachys, *Busk* (*op. cit.* pl. xvii. figs. 3, 4, pl. xviii. figs. 1–4).
3. „ *Var. a*, fossaria, *Hincks.*
4. „ catenularia, *Jameson* (p. 134, pl. xvii. figs. 1, 1*a*, 2).
5. „ pilosa, *Linnæus* (*op. cit.* p. 137, pl. xxiii. figs. 1–4).
6. „ *Var. a*, dentata, *Hincks.*
7. „ *Var. β*, laxa, *Smitt.*
7* „ *Var. γ*, (*Pallas's* sp.)
8. „ membranacea, *Linn.* (*op. cit.* p. 140, pl. xviii. figs. 5–6).
9. „ hexagona, *Busk* (*op. cit.* p. 143, pl. xviii. fig. 7).
10. „ lineata, *Linn.* (*op. cit.* p. 143, pl. xix. figs. 3–6).

11. Membranipora craticula, *Alder* (p. 147, pl. xix. fig. 7).
12. „ spinifera, *Johnston* (p. 149, pl. xix. fig. 1, &c.).
13. „ flustroides, *Hincks* (p. 151, pl. xix. fig. 2).
14. „ discreta, *Hincks* (p. 152, pl. xix. figs. 8, 9).
15. „ curvirostris, *Hincks* (p. 153, pl. xx. figs. 5, 6).
16. „ unicornis, *Fleming* (p. 154, pl. xx. fig. 4).
17. „ Dumerilii, *Aud.* (p. 156, pl. xx. fig. 3).
18. „ solidula, *Alder* and *Hincks* (p. 158, pl. xx. figs. 7, 8).
19. „ aurita, *Hincks* (p. 159, pl. xxi. figs. 5, 6).
20. „ imbellis, *Hincks* (p. 160, pl. xx. figs. 1, 2).

b. *With a calcareous lamina.*

21. Membranipora Flemingii, *Busk* (p. 162, pl. xxi. figs. 1–3).
22. „ cornigera, *Busk* (p. 164, pl. xxi. fig. 4; pl. xxii. fig. 3).
23. „ Rosselii, *Aud.* (p. 166, pl. xxii. fig. 4).
24. „ trifolium, *S. Wood* (p. 167, pl. xxii. figs. 5, 6).
25. „ minax, *Busk* (p. 169, pl. xxii. figs. 2 to 2c).
26. „ nodulosa, *Hincks* (p. 170, pl. xx. fig. 9).

As the whole of the above species are described and figured in the 'Brit. Mar. Polyzoa,' I have not thought it necessary to load my text with the synonymy, range in space and time, and the localities, given so fully by Mr. Hincks. This will be given in tabular form. Some of the species are very widely distributed round our coast, others are more restricted in their range; but as no one would attempt to describe the Polyzoa without consulting this book, I believe the mere name of the species will be a sufficient introduction to future students. From what I have seen of Mr. Shrubsole's specimens, collected from Llandudno, I may say that in this locality the collector may gather a rich harvest of forms. At Hastings, Devon, and Cornwall, both from the shore *débris* and also from deep-sea dredgings, many species may be collected; but as some few of the localities are really classical hunting grounds, I shall consider it to be an advantage, rather than a disadvantage, to give separate lists—without much special details—of these places.

The following appear in Mr. A. W. Waters's papers on the 'Bryozoa of the Bay of Naples,' but I have only numbered those species which are really additions to the British list ('Ann. Mag. Nat. Hist.,' Feb. 1879, pp. 121, 122).

Membranipora pilosa, *Pall.*
„ membranacea, *Linn.*
„ Rosselii, *Aud.*
„ Flemingii, *Busk*, pl. xiii. fig. 2 (see No. 228).
„ *Var.* gregaria, *Heller*, pl. xiii. fig. 5
= M. gregaria, *Heller*, 'Die Bryoz. des Adriatic'
= M. aperta, *Manzoni*, 'Castrocaro.'
27. „ angulosa, *Reuss.*, pl. xiii. fig. 3.

For very full details of fossil species of Membranipora, which range from Recent to Eocene both in Europe and Australia, see the 'Fifth Brit. Assoc. Report on Fossil Polyzoa,' 1884, Montreal (*mihi*), Nos. 42 to 73.

In a series of papers, 'Contributions towards a General History of Marine Polyzoa,' the Rev. Thomas Hincks has described and figured many new forms of *Membranipora* from several localities. Many of these species were collected by Miss E. C. Jelly and Miss Gatty, and submitted to Mr. Hincks for examination. I have only numbered the new forms—or new to present list.

MADEIRA SPECIES.

28. Membranipora tenuirostris, *Hincks*, pl. ix. fig. 3
= M. Flemingii, *Waters*, Bay of Nap. Pol. 'Ann. Mag. Nat. Hist.,' February 1879.
29. " nodulifera, *Hincks*, pl. ix. fig. 2.
30. " crassimarginata, *Hincks*, pl. ix. fig. 1.
31. " granulifera, *Hincks*, pl. ix. fig. 4.
(This species belongs to the *M. Flemingii* group.)
32. " sceletos, *Busk* = Lepralia, *id.*, 'Quart. Jour. Mic. Soc.' 1858. 'Zoophytology,' *Busk*, pl. xx. fig. 3.

From the Contributions towards a General History of the Marine Polyzoa, Rev. T. Hincks, 'Ann. Mag. Nat. Hist.' vol. vi. 1880, pp. 69–91. In the same contribution, Part II., Mr. Hincks describes in full the following species under various divisions (p. 81, &c.) :—

a. *Species with a membranous front wall.*

33. Membranipora albida, *Hincks*, pl. x. fig. 5. *Loc.*: Singapore; on Tubipora musica. Allied to M. curvirostris, *Hincks*.
34. " plana, *Hincks*, pl. xi. fig. 2. *Loc.*: Australia.
35. " armifera, *Hincks*, pl. xi. fig. 5. *Loc.*: Gulf of St. Lawrence; on Flustra membranacea. Allied to M. sophiæ, *Busk*.
36. " horrida, *Hincks*, pl. x. fig. 6. *Loc.*: California.
37. " Carteri, *Hincks*. Australia. Mr. Hincks speaks of this species as having a special interest, 'as being the only known Membranipora which possesses a fully developed bird's head appendage identical in structure with that of the genera *Bugula* and *Bicellaria*.' And in a note he adds that *M. minax*, Sm. (= M. princeps, *Hincks*) is furnished with an avicularia which has the form of the bird's head, but it is fixed. *M. Carteri* has the appendage articulated.
38. " pura, *Hincks*, pl. xi. fig. 3. Australia or New Zealand.
39. " villosa, *Hincks*, pl. x. fig. 8.

a′. *Cell prolonged below the aperture.*

40. Membranipora distorta, *Hincks*, pl. x. fig. 7. *Loc.*: Ceylon. There is evidence of affinity between this interesting form and the common M. pilosa.

b. *With a calcareous lamina.*

41. Membranipora nitens, *Hincks*, pl. xi. fig. 4. Australia; on Polyzoa. 'Certainly distinct,' says Mr. Hincks, 'from the South Atlantic M. tuberculata, *Bosc.*'

42. Membranipora delicatula, *Busk*, pl. xi. fig. 1. Biflustra, *id.*, Crag Polyzoa. ? Biflustra deliculata, *Smitt.* 'Florid. Bry.' (Not. M. deliculata, *Busk.*)
43. " trifolium, *S. Wood. Var.* minor, *Hincks*, pl. xi. fig. 6. *Loc.*: Bahia; on shell.
44. " antiqua, *Busk*, pl. xi. fig. 7. *Busk*, 'Quart. Jour. Mic. Soc.' vol. vi. p. 262, pl. xx. fig. 12.

c. *With a membranous front wall, the orifice surrounded by a border. Operculum with a distinct hinge.*

45. Membranipora mamillaris, *Lamx.*, pl. x. fig. 9. *Loc.*: Australia.
46. " transversa, *Hincks*, pl. xi. fig. 9. Seems to be nearly related to M. Woodsii, *Macgil.*

a. *With a membranous front wall.*[1]

47. Membranipora coronata, *Hincks*, p. 147, pl. x. fig. 1. *Loc.*: Singapore; on coral.
48. " terrifica, *Hincks*, pl. viii. fig. 5. *Loc.*: Straits of Magellan; on Eschara flabellaris, *Busk.*
49. " rubida, *Hincks*, pl. viii. fig. 6. *Loc.*: Australia; on stone.
50. " bicolor, *Hincks*, p. 148, pl. ix. fig. 1. *Loc.*: West Australia.
51. " bellula, *Hincks*, p. 149, pl. viii. figs. 4, 4*a*, 4*b*.
51*a*. " " *Var.* α, bicornis.
51*b*. " " " β, multicornis. *Loc.*: Normal and var. β, Australia, Ceylon; *var.* α, Madagascar, St. Vincent, Cape Verd Islands.

b. *With a calcareous lamina.*

52. Membranipora patula, *Hincks*, p. 150, pl. ix. fig. 4. *Loc.*: California.
53. " setigera, *Hincks*, pl. viii. fig. 3. *Loc.*: Australia, investing Serpula. M. setigera belongs to the same section of the genus as our own British species, M. Rosselii and M. trifolium.
54. " spinosa, *Quoy* and *Gaimard*.
= flustra, *id.*, *Quoy* and *Gaimard*, 'Voy. de l'Astrolobe.'
= M. ciliata, *Macgil*, Transac.
= M. spinosa, *Busk*, 'Polyzoa of Kerguelen Island.' D'Orb. describes a species of M. spinosa ('Voy. dans l'Amér.') which bears a close resemblance to M. spinifera, *Johnst.* *Loc.*: Kerguelen Island; Australia; Arabian Sea, between Bombay and Aden.
55. " permunita, *Hincks*, p. 151, pl. x. fig. 2. *Loc.*: Off Curtis Island, Bass's Straits.
56. " denticulata, *Macgil.* pl. viii. fig. 2
= Caleschara, *id.*, 'Prod. Zool. Vict.'

[1] Continuation of Papers by Mr. Hincks, *Ann. Mag. Nat. Hist.*, Feb. 1881.

57. Membranipora cervicornis, *Busk*, pl. viii. fig. 1, pl. x. fig. 3. Mr. Hincks (pp. 153, 154) gives several interesting particulars of this form.

In Captain Warren's collection of Polyzoa, in the possession of the Free Museum, Liverpool, Mr. Hincks gives additional particulars of new Membranipora ('Ann. Mag. Nat. Hist.,' July 1881).

58. Membranipora pyrula, *Hincks*, pl. i. fig. 2, p. 3 = M. lineata, *Macgil.*, 'Prod. Zool. Victoria.' *Loc.*: Bass's Straits.
59. „ inarmata, *Hincks*, pl. iv. fig. 4.
53. „ vitrea, *Hincks*, pl. i. fig. 1. *Loc.*: Curtis Island.
54. „ punctigera, *Hincks*, pl. i. fig. . *Loc.*: Curtis Island; on *Retepora.*
55. „ radicifera, *Hincks*, pl. ii. figs. 6, 6*a*.
56. „ inornata, *Hincks*, pl. iv. fig. 5. *Loc.*: Bass's Straits.
57. „ roborata, *Hincks*, pl. ii. fig. 3. [This species seems to occupy a somewhat intermediate place between *Flustra* and *Membranipora.*] *Loc.*: Off Curtis Island.

In another paper ('Ann. Mag. Nat. Hist.,' August 1881) Mr. Hincks describes the following species:—

58. Membranipora amplectens, *Hincks*, pl. iii. fig. 7. *Loc.*: Australia. Species allied to *M. pilosa*, but differs from it in many points.
59. „ vetata, *Hincks*, pl. v. fig. 3.
60. „ circumclathrata, *Hincks* (*op. cit.*), p. 131, pl. v. fig. 1.
61. „ variegata, *Hincks* (*op. cit.*), pl. v. fig. 2. *Loc.*: Santa Cruz, California; Nos. 59–61.
„ pilosa, *Linn.* Form, multispinata, *Hincks*, 'Annals,' Feb. 1882, pl. v. fig. 6.

In the 'Annals,' November 1880, vol. vi. 5th series, five species are described:—

Membranipora tenella, *Hincks* (*op. cit.*), p. 376, pl. xvi. fig. 7. *Loc.*: Florida; on weed.
„ Flemingii, *Busk.*
Var. (*op. cit.*) p. 376, pl. xvi. fig. 8. A spineless form of Busk's species.
„ pedunculata, *Manzoni*, pl. xvii. figs. 2, 2*a*. *Loc.*: Ceylon; on weed.
„ polita, *Hincks* (*op. cit.*), pl. xvii. fig. 1. *Loc.*: Glenelg., Australia.
„ corbula, *Hincks* (*op. cit.*), p. 378, pl. xvii. fig. 6. *Loc.*: Australia.

Polyzoa of India, coast of Burmah, Contributions, *Hincks*, 'Annals,' May 1884, p. 257.

Membranipora favus, *Hincks* (*op. cit.*), pl. xiii. fig. 3.
„ marginella, *Hincks* (*op. cit.*), pl. xiii. fig. 1.

In his Report on the Polyzoa of Queen Charlotte Island, 'Geological and Natural Hist. Survey of Canada' (=Papers in 'Annals,' December 1882, June 1883, January 1884, March 1884), Mr. Hincks gives very elaborate details of the following species :—

Membranipora variegata, *Hincks*, Queen Charlotte Island; California. 'Specimens occur in which there are two of the pedicellate avicularia at opposite sides of the cell instead of the normal one.'

" acifera, *Macgil.* Form, multispinata, *Hincks*, 'Annals,' Dec. 1882, pl. xix. fig. 4. *Loc.*: Virago Sound, Victoria, *Macgil.*

" echinus, *Hincks* (*op. cit.*), pl. xix. fig. 5 (p. 8 of Report). *Loc.*: Houston Stewart Chan.; Cumshewa, 20 fathoms.

" exilis, *Hincks* (*op. cit.*), pl. xx. fig. 1. *Loc.*: Houston Stewart Chan.

" Sophiæ, *Busk.* Form, matura, *Hincks* (*op. cit.*), pl. xx. fig. 2. 'Described as *M. conferta* ('Annals' for September 1882). I am now convinced that it is a form of *M. sophiæ*. Smitt notices intermediate varieties.'—*Hincks*. *Loc.*: Houston Stewart Chan., Spitzbergen.

" nigrans, *Hincks* (*op. cit.*), pl. xix. figs. 2, 2*a*. *Loc.*: Houston Stewart Chan.; Virago Sound.

" levata, *Hincks* (*op. cit.*), pl. xix. figs. 6, 6*a*. *Loc.*: Houston Stewart Chan.; Cumshewa.

" protecta, *Hincks* (*op. cit.*), pl. xix. fig. 3. *Loc.*: Virago Sound; Cumshewa. 'Other species,' says Mr. Hincks, 'armed with more or less branching spines' are—

" cornigera, *Busk*, Shetland.

" bellula, *Hincks*, Australia.

" cervicornis, *Busk*, Victoria.

" cervicornis, *Haswell*, Queensland.

Haswell's name cannot be retained, having been previously employed by Busk. I venture to suggest the following as a substitute for it.—*Hincks.*

" Haswellii, *Hincks.*
= M. cervicornis, *Haswell.*

" corniculifera, *Hincks*, 'Annals,' December 1882, pl. xx. figs. 4, 4*a*. *Loc.*: Cumshewa.

" minuscula, *Hincks* (*op. cit.*), pl. xx. figs. 3, 3*a*.

" membranacea, *Linn.* Form, serrata, *Hincks*. *Loc.*: Virago Sound.

" pallida, *Hincks*, 'Annals,' Appendix, March 1884. 'Annals' and 'Mag. Nat. History,' vol. xv., *Hincks*, Contributions, &c. vol. xv., March 1885.

" valdemunita, *Hincks* (*op. cit.*), pl. vii. fig. 2. *Loc.*: Napier, New Zealand.

" hians, *Hincks* (*op. cit.*), pl. vii. fig. 5. *Loc.*: New Zealand.

" acuta, *Hincks* (*op. cit.*), pl. vii. fig. 6. *Loc.*: New Zealand.

Membranipora perfragilis, *Macgil.* = Biflustra, *id.*, 'Nat. Hist. of Victoria,' Decade VI. p. 27. Figure of Avicularia, and description given by *Hincks*, 'Annals,' October 1884, pl. vii. fig. 4. *Loc.*: Victoria, Australia.

In the description of New Polyzoa collected by J. Y. Johnson, of Madeira, in the years 1859 and 1860, as Mr. George Busk gave the first list of *Membranipora* in the 'Quart. Jour. Mic. Soc.' 1858, 1860, 1861, it would be indiscreet on my part not to give it, together with the original references.

Membranipora tuberculata, *Bosc.*, pl. xviii. fig. 4, formerly confounded with *M. membranacea* (see *ante*, 41).
" trichophora, *Busk*, pl. xviii. fig. 2.
" antiqua, *Busk*, pl. xx. figs. 1, 2 (No. 44).
" Rosselii, *Aud.* (see No. 23).
" Lacroixii, *Aud.* (see No. 1).
" lineata, *Linn.* (see No. 10).
" calpensis.

For details of Recent Scandinavian Membranipora and Synonyms, see 'Fifth Report on Fossil Polyzoa,' Brit. Assoc. 1884, where I have given a full list of Smitt's identifications. Part II. Historical Labours, p. 58 of Report. No. 19 to No. 28.

Genus 37 (?). Megapora, *Hincks.*

'Ann. Mag. Nat. Hist.' 1877; 'Brit. Mar. Polyzoa,' p. 171.

'Zoarium encrusting. Zoœcia, with a depressed area in front, surrounded by a raised margin, and partially closed in by a calcareous lamina; aperture trifoliate, the lower portion filled in by a horny plate on which the opercular valve works.'—*Brit. Mar. Pol.* p. 171.

Megapora ringens, *Busk*, 'Brit. Mar. Pol.' p. 172, pl. xxii. fig. 1 = Lepralia ringens, *Busk*, 'Quart. Jour. Mic. Soc.' 1856, p. 308, pt. 308, pl. ix. figs. 3–5; *Norman*, Shetland Polyzoa, 'Brit. Assoc. Rep.' 1868, p. 307.

This is a deep-water form, and the localities and geographical distribution very limited. *Loc.*: Shetland, 80–170 fathoms; Bergen.

Membraniporidæ, *Hincks.*

Genus Siphonoporella, *Hincks.*

'Ann. Mag. Nat. Hist.' Contributions, July 1880.

'Zoœcia with raised margins, front depressed, in part membranaceous, a small calcareous tube with wide mouth placed at one side of the lamina, below the aperture, and opening into the cavity of the cell. Zoarium in only known species encrusting.'—*Hincks.*

Siphonella nodosa, *Hincks, op. cit.* pl. xi. fig. 10.

Genus Euthyris, *Hincks.*

'Ann. Mag. Nat. Hist.' vol. x. 5th ser. 1882.

? THAIROPORA, *Macgil.* 'Trans. Roy. Soc. Victoria,' Dec. 1881.

Zoarium corneous, erect and foliaceous. Zoœcia with raised margins, aperture closed by a membranaceous (or membrano-calcareous) wall;

orifice surrounded by a chitinous border; oral valves furnished with a distinct fringe.

Euthyris obtecta, *Hincks* (*op. cit.* pl. vii. fig. 3). *Loc.*: Australia.

Macgillivray recently constituted a genus under the name THAIROPORA, *Macgil.*, for a parallel group amongst the *Membraniporidæ*, and Mr. Hincks says, 'we must recognise here the characters of a generic group, in which Carbasea episcopalis, *Busk*, and C. bombycinna, *Ellis & Solander*, will rank, as well as the species E. obtecta, *Hincks*.' As a set off against this it will be seen that Mr. Busk—'Challenger Report'—places these species in new divisions.

Family XII. **Microporidæ**, *Busk*

= 'Challenger Report,' p. 70
= Microporidæ (pars), *Smitt*, *Hincks*
= Membranipora (pars), *Authors.*

'The much depressed front of the zoœcia beneath the chitinous epitheca, wholly occupied, except at the summit, by a strong calcareous lamina, usually perforated or fissured on the sides, and sometimes forming a transverse diaphragm, which divides the cavity of the zoœcium into two chambers.'—*Op. cit.* p. 70.

1. Genus Micropora, *Gray.*
2. ,, Vincularia, *Defrance.*
3. ,, Steganoporella, *Smitt.*
4. ,, Caleschara, *Macgillivray.*
5. ,, Diplopora, *Macgillivray.*
6. ,, Setosella, *Hincks.*

Genus 38. Micropora, *Gray*

= Membranipora (pars), 'Brit. Mus. Catalogue'
= Lepralia (sp.), *Norman*; Steganoporella (sp.), *Hincks*
= Repteschareilina (pars), *D'Orb.*

'Zoarium incrusting. Zoœcia with an internal calcareous lamina occupying the entire area, with a perforation at each upper angle below the orifice, which is apical, with a continuous calcareous peristome.'—*Chal. Rep.* p. 70.

1. Micropora uncifera, *Busk*, 'Chal. Rep.' pl. xv. fig. 7.
2. ,, coriacea, *Esper*, 'Chal. Rep.' p. 71.
These are the only two species of this genus in the 'Challenger' collection.

In his 'British Marine Polyzoa,' Mr. Hincks describes two species only.

Micropora coriacea, *Esper*, *op. cit.* p. 174, pl. xxiii. figs. 5–7.
3. ,, complanata, *Norman*, *op. cit.* pl. xxiii. figs. 8, 9
= Lepralia, *id.*, 'Ann. Nat. Hist.' 1864 (*Norman*)
= Membranipora, *Smitt*, *Manzoni.*

M. coriacea, *var. Hincks*, 'Polyzoa Bass's Straits.' 'Avicularia are more freely developed than in British specimens.'

4. Micropora elongata, *Hincks* = Steganoporella, *id.*, *Hincks*, Africa.
5. ,, Jervoisii, *Hincks*=Steganoporella, *id.*, *Hincks*, Australia, 'Annals,' Nov. 1880, pl. xvi. figs. 4, 5.

Genus 39. Vincularia, *Defrance.*

See 'Challenger Report,' p. 71.

'Zoarium erect, continuous, branched or simple; radicate or fixed. Sub-cylindrical or polygonal. Zoœcia disposed in alternate longitudinal series. Frontal area quadrangular, oblong, arched above, in the natural state filled in by a chitinous epitheca, in which is seated the oral orifice. Beneath the epitheca a calcareous lamina occupying the lower two thirds of the area, and terminating above in a free border, from which a median process arises, which joining above a process from each side of the zoœcia on a level with the lower border of the orifice forms with those processes a transverse ridge, with an arch on each side of the median process. Opercula incomplete below, composed of a thickish membrane supported on the inner face by a strong chitinous bow having a projecting process near each lower angle for the attachment of the occlusor muscles. Oœcia represented by a small chamber in the upper part of the cell, which opens above the oral orifice.'—*Chal. Rep.* p. 72.

It is very evident that following the above clear definition of what Mr. Busk considers as the true probable limit of *Vincularia*, Defrance, many ill-defined fossil species must fall out of the list. Although only proposed provisionally, *Vincularia*, thus defined, have very many natural characters for its recommendation; but still many points in the structure of some of the species have been discussed by Mr. A. W. Waters; by Mr. Hincks, in 'Ann. Mag. Nat. Hist.' 5th ser. vol. ix. 1882, p. 119; and now by Mr. Busk in the 'Challenger Report.' I have already discussed the fossil species in my last Brit. Assoc. Rep., Fam. VII. Cellariidæ, and all that I am prepared to do now is to catalogue the species described by authors in their various papers. But it seems to me that if we retain the genus *Vincularia*, it ought to be mentioned by future authors as to whether they accept the genus as defined by Mr. Busk in the 'Challenger Report,' or record their species on the basis of the ill-defined generic characters of previous authors.

In the 'Challenger Report' Mr. Busk has given good woodcut illustrations (pp. 72, 73) of the chitinous arch of two of the species described.

1. Vincularia gothica, *D'Orb.* 'Chal. Rep.' pl. xxiii. fig. 1.
   Vincularia id., 'Palæon. France,' p. 68
   = ,, Novæ-Hollandiæ, *Haswell*
   = ,, steganoporoides, *Macgil.*, New Sp. Bry.
2. ,, gothica, *var.* granulata, *Busk*, 'Chal. Rep.' p. 73.
3. ,, labiata, *Busk*, 'Chal. Rep.' p. 73.

In the 'Brit. Mus. Cat.' Mr. Busk described two species—

Vincularia ornata.
,, Neo-Zelanica (see *Steganoporella*).

Mr. Busk remarks of *V. steganoporoides*, Macgil. (No. 1), that it is regarded by Mr. Hincks ('Gen. Hist. Mar. Pol.,' 'Ann. Mag. Nat. Hist.' 5th ser. vol. ix. p. 119) as a form of his *Steganoporella Smittii* ('Brit. Mar. Pol.' p. 178), which, however, I should myself refer to the genus

Micropora. It is clearly quite distinct from Mr. Macgillivray's species ('Chal. Rep.' p. 72, note 2).

Genus 40. Steganoporella, *Smitt.*

Florid. Bryozoa

= Steganoporella, *Hincks*, 'Brit. Mar. Pol.'; *Waters*; *Macgil.*
= Vincularia (sp.), *D'Orb.*

'Zoarium polymorphous; erect and branched, or lobate or decumbent, and foliaceous and crustaceous. Zoœcia oblong and arched above. Frontal area occupied by a delicate chitinous membrane, which is closely adnate to the internal calcareous lamina for about the lower half of the area; above free, and supporting the operculum, and having on each side below the orifice a minute forked or irregularly branched vertical chitinous rod. Opercula large, semicircular, usually of two kinds, the membranous portion supported by a branching chitinous framework. A strong internal calcareous lamina, which, about the middle of the length of the cell, bends backward to the posterior wall, forming a transverse diaphragm, by which the cell is divided into two distinct chambers, communicating with a phrenic opening through which the polypide is protruded, supported on or passing over a large hollow process rising from the upper and anterior part of the transverse diaphragm.'—*Chal. Rep.* p. 74.

1. Steganoporella magnilabris, *Busk*, 'Chal. Rep.' p. xxiii. fig. 2, and woodcuts, p. 76
 = Membranipora, *id.*, 'Brit. Mus. Cat.'
 = Steganoporella elegans, *Smitt*, Flor. Bry.
 = ,, magnilabris, *Hincks*; *Waters*; *Macgil.*
 = (?) Biflustra crassa, *Haswell*
 = Steganoporella Neo-Zelanica (sp.), *Waters.*
2. ,, Neo-Zelanica, *Busk.* Referred to 'Chal. Rep.' pp. 74 and 76
 = Vincularia Neo-Zelanica, *Busk*, 'Brit. Mus. Cat.'
3. ,, Smittii, *Hincks*, 'Brit. Mar. Pol.' p. 178. See note in this Report on *Vincularia gothica (ante).*

Family Steganoporellidæ, *Hincks.*

'Ann. Mag. Nat. Hist.,' May 1884.

Mr. Hincks, in one of his contributions ('Annals,' May 1884, 5th ser. vol. xiii. p. 358), says Smitt places the genus *Steganoporella* 'among the Microporidæ, and I have given it the same position in my history of the British Marine Polyzoa. But I am now inclined to agree with Dr. J. Jullien[1] so far as to regard the dithalamic condition of the zoœcium which distinguishes it as entitling it to rank in a separate *family* group. It is only right, however, that the name of the group should be taken from Smitt's genus *Steganoporella*, which is founded on the division of the

[1] 'Note sur une nouvelle division des Bryozoaires Cheilostomiens.' *Bull. de la Soc. Zool. de France*, t. vi. 1881.

zoœcium into an upper and lower chamber by the interposition of a calcareous lamina beneath the membranous front wall.' But Mr. Hincks says that he is unable to follow Dr. Jullien in his proposed distribution of the Cheilostomata into two principal groups, characterised by the presence or absence of this double ectocyst. . . . There is room, however, for a fuller investigation of its history and meaning.

After duly considering the question raised by Dr. Jullien, Mr. Hincks believes that there are at least two distinct generic types—there may be more—and these are represented by the species given below:—

Genus. Steganoporella.

Steganoporella magnilabris, *Busk* (see *ante*).

Genus. Smittipora, *J. Jullien.*

Smittipora abyssicola, *Smitt.*

I at one time referred the above species to *Setosella* (*mihi*), but the British species (*S. vulnerata*), for which this genus was founded, does not possess the dithalamic cell.

Two species, formerly described as *Steganoporella*, are now referred to *Micropora.*

Genus 41. Caleschara Macgillivray.

(See *Busk*, 'Chal. Rep.' p. 76.)

'Zoarium polymorphous; erect, foliaceous, and contorted, or composed of ligulate branches and bilaminar, or decurrent and incrusting. Zoœcial area pyriform; the margin very thick and bevelled off to a considerable depth, so as to leave a very contracted elliptical aperture, at first membranous, but eventually occupied in the lower two-thirds by a calcareous lamina attached below to the bottom of the aperture, and above by a broad band on each side, and leaving on either side an elongated fissure. The upper third above the lamina represents the internal or secondary orifice. In the natural state the entire area is filled in by a rather thick epithecal membrane, in which alone is seated the semicircular or subcrescentic operculum. Fertile cells distinguished by their greater width.' —*Chal. Rep.* pp. 76 and 77.

Caleschara denticulata (?) *var.* tenuis, *Busk.*
'Chal. Rep.' p. xxi. fig. 9.
See *Hincks*, 'Ann. Mag. Nat. Hist.' Feb. 1881, p. 152, pl. viii. fig. 2.

Genus 42. Diplopora, *Macgillivray.*

'Zoarium incrusting; cells occupied by a calcareous membrane in front, and divided into two parts, the posterior half being very much elevated; a narrow transverse portion a little distance behind the mouth, and in front of the elevated part, deficient in calcareous matter and entirely membranous.'—*Macgillivray*, Proceed. Roy. Soc. Victoria. Diplopora cincta (Hutton's sp.). *Loc.*: Queenscliffe; Portland (*Mapleston*).

This is the Membranipora cincta of Hutton, and is the same species that has been described as *Membranipora transversa* by Mr. Hincks.

Genus 43. Setosella, *Hincks*, 'Brit. Mar. Pol.' p. 180
= Membranipora (pt.), *Busk*
= Cupularia (part), *Smitt*, 'Florid. Bryoz.' ii. 14
= Setosella, *Hincks*, 'Ann. Mag. Nat. Hist.' 1877
= Setosella. Referred to only 'Chal. Rep.' p. 70.

'Zoarium incrusting. Zoœcia with raised margins; front depressed and wholly calcareous; aperture semicircular. Vibracular cells alternating with the zoœcia throughout the colony. Vibraculum slender and setiform.'—*Op. cit.* p. 180.

Setosella vulnerata, *Busk* ('Brit. Mar. Pol.' p. 181, pl. xxi. fig. 7)
= Membranipora id., *Busk*, 'Quart. Jour. Mic. Soc.' viii. pl. xxv. fig. 3, *Norman.*
" Shetland dredgings, 'Brit. Assoc. Rep.' 1867, p. 305
= Setosella vulnerata, *Hincks* ('Ann. Mag. Nat. Hist.' 1877).

Family XIII. **Electrinidæ**, *Busk*

= Electrinidæ, *D'Orb.*, 1851, 'Palæon. France,' p. 329
= Membraniporidæ (pars), *Auctt.*

'Zoarium erect or incrusting, more or less flexible or sub-testaceous. Zoœcia turbinate or sub-turbinate. Wall punctured. A wide expanding aperture, the border toothed or furnished with chitinous or aculeate spines. One or more chitinous spines, of larger size than the rest, articulated on the front of the zoœcium below the aperture, or an articulated avicularian process in the same situation. Oœcia when present galeate.'—*Chal. Rep.* p. 78.

Genus 44. Electra, *Lamouroux.*

Character: That of the family.

This family seems to be founded upon two well-known types of Polyzoa: the not too well-known *Electra verticillata* (Lamx.), and the well known and widely distributed *Electra* (Membranipora) *pilosa* (Linn.).

In his 'Brit. Mar. Pol.' (p. 137) Mr. Hincks places the *M. pilosa* with the group having a membranous front wall, but he does not make any remarks upon the species as being probably taken as the type of any new family, although from the very full list of synonyms furnished by him a doubt as to its future location may have arisen in his mind. Three varieties are described in the 'Brit. Mar. Pol.' which will be mentioned in their proper place. In the 'Chal. Rep.' only one new species is described, but Mr. Busk suggests that perhaps four or five described forms may be included in the genus, as here defined.

1. Electra cylindrica, *Busk*, 'Chal. Rep.,' pl. xxxiii. fig. 2, not *E. cylindrica*, *D'Orb.*
2. " pilosa, *Linn.* (see 'Brit. Mar. Pol.' p. 137).
   Var. α, dentata, *Hincks* (*op. cit.* p. 137).
   " *β*, laxa, *Smitt* (*op. cit.* p. 137).
   " *γ*, *Pallas* (*op. cit.* p. 138).
3. " verticillata, *Lamx.*, 'Flexible Coralines.'
4. " triacantha, *Lamx.*
5. " bellula, *Hincks.*
6. " (?) distorta, *Hincks.*

The original description of Lamouroux (' Flex. Coral.') may be given here:—

' Electra.

' " Flex. Coral," ed. 1824, translated, p. 53.

' Polypidoms branching; cells campanulated, ciliated on their border, and verticillated. . . . The electra is very common in the European seas; when the polypi are alive their colour is a red violet of greater or less brilliancy; but when exposed to air and light it becomes an earthy white.' —' Electra verticillata,' *Lamouroux, op. cit.* pl. 2, figs. a, b, 2.

Group C. Escharina, *Busk.* ' Challenger Rep.' p. 79.

Family XIV. **Bifaxariadæ,** *Busk.*

' Zoarium rigid, continuous or articulated, biserial, variously branched. Zoœcia alternate, closely connate back to back and facing in opposite directions.'—*Chal. Rep.* p. 79.

Genus. Bifaxaria, *Busk.* Genus. Calymmophora, *Busk.*

Genus 45. Bifaxaria, *Busk.*

' Zoarium continuous or segmented, variously branched, rooted by radicle tubes. Zoœcia biserial, alternate, facing bifariously on the two sides, very closely contiguous. Orifice elliptical from side to side, or semi-orbicular or sub-orbicular. Peristome sometimes sub-tubular, sometimes deeply immersed. A small circular immersed avicularium on each side of the orifice, sometimes wanting, or replaced by a short hollow spinous process. Oœcia, when present, deeply imbedded in the superjacent zoœcium. A raised ridge or keel on the middle of the front, the upper pointed termination of which constitutes a more or less prominent mucro in front of the orifice.'—*Chal. Rep.* pp. 79, 80.

§ a. Articulatæ.

1. Bifaxaria submucronata, *Busk*, ' Chal. Rep.' pl. xiii. fig. 1.
2. „ lævis, *Busk.* ' Chal. Rep.' pl. xiii. fig. 2
   = Antipathis humilis, *Agassiz* and *Pourtalès.*

§ β. Inarticulatæ.

3. „ corrugata, *Busk*, ' Chal. Rep.' pl. xiii. fig. 3; and pl. xxiv. fig. 6.
4. „ papillata, *Busk*, ' Chal. Rep.' pl. xiii. fig. 4; and pl. xxiv. fig. 4.
5. „ minuta, *Busk*, ' Chal. Rep.' pl. xiii. fig 5.
6. „ reticulata, *Busk*, ' Chal. Rep.' pl. xiii. figs. 6 and 8.
7. „ abyssicola, *Busk*, ' Chal. Rep.' pl. xxiv. fig. 5.
8. „ denticulata, *Busk*, ' Chal. Rep.' pl. xxiv. fig. 3.

Genus 46. Calymmophora, *Busk.*

' Zoarium continuous, irregularly branched; biserial; the zoœcia alternate, placed back to back facing in opposite directions, pyriform, squarely truncated at the top, with a hollow conical process at each angle, often supporting a small avicularium. Orifice large, orbicular, with a wide notch in front, terminal (looking directly upwards). Oral valve semicircular, curved transversely, with numerous perforations. Wall

exceedingly delicate, with a very slender median and two lateral ridges, and a row of very distant pores on each side, and a few of smaller size on the sides and below the orifice. Oœcia galeriform, completely immersed in front of the superjacent zoœcium, and covered with the general epithecal membrane with which the entire growth is enveloped as in a loose veil.' —*Busk*, 'Chal. Rep.' pp. 82, 83.

Calymmophora lucida, *Busk*, *op. cit.* pl. xxxii. fig. 3.

The only species of the genus, and obtained from station 163*a*. Twofold Bay, 150 fathoms.

Family XV. **Salicornariadæ**, *Busk*, 'Chal. Rep.'
'Brit. Mus. Cat.' (pars), 'Crag Polyzoa,' (pars)
= Cellariidæ, *Hincks*, 'Brit. Mar. Polyzoa.'

'Zoarium erect, radicate or fixed; simple, branched or lobed; segmented or continuous; cylindrical, with the cells disposed round an imaginary axis, or compressed and bilaminar; surface areolated. Zoœcia completely immersed, each corresponding to an area; front depressed, usually concave. Orifice crescentic, semicircular, or elliptical. Oœcia inconspicuous, opening at or near the summit of the area above the orifice. In the decalcified condition the interareolar septa exhibit a delicate chitinous, probably tubular, filament, apparently continuous throughout the segment; and on each side of the oral orifice a slender curved chitinous rod or trabecula, which sometimes unite so as to form a complete or incomplete ring. Avicularia usually present, either vicarious or intercalated.'—*Chal. Rep.* p. 84.

As CELLARIIDÆ, *Hincks*, I gave a tolerably fair account of this family group in my fifth British Report on Fossil Polyzoa. In that Report I dealt, as a matter of course, with fossil species only, which appeared to me to be rather more abundant than recent forms. It may now, in justice to the respective authors, be as well to allude to the classification of Mr. Hincks before passing on to the 'Challenger Report.'

In 1879 ('Ann. Mag. Nat. Hist.') Mr. Waters gave only a single species in his 'Bay of Naples Bryozoa.' The genus, says Mr. Hincks, 'possesses a very cosmopolitan representative in our own *C. fistulosa*,' and although *Cellariæ* are widely distributed, the foreign specimens differ but slightly from British forms, if a large number of cells are studied and compared. In the fifth Report I gave conclusions arrived at by Mr. Waters after a careful study of a large series of specimens collected from several localities. In dredgings in the Bay of Naples a vast quantity of fragmentary specimens of *C. fistulosa*, Linn., may be obtained, and the careful study of these in association with the British forms will afford a large amount of practical details of species when dealing with British and foreign species. The brief description of the family group, as given by Mr. Hincks, is markedly conspicuous when compared with the fuller description of Mr. Busk.

'Zoarium usually rhomboidal or hexangular, disposed in series round an imaginary axis, so as to form cylindrical shoots. Zoarium erect, calcareous, dichotomously branched.'—*Hincks*, p. 103.

As, however, only three species are described as British, it may be well to give these first, and then refer the student to the 'British Marine Polyzoa,' for very full details.

Cellariidæ, *Hincks*, 'Brit. Mar. Polyzoa'; *A. W. Waters*, Bryozoa, Bay of Naples; Papers on Australian Bryozoa (fifth Report 'Brit. Assoc.' 1884 on Fossil Polyzoa), &c.

Genus Cellaria, *Lamouroux* (part)

= Salicornia, *Schweigger*; Salicornaria, *Cuvier*; Salicornaria, *Busk*; Farcimia, *Fleming*.

Celaria fistulosa, *Linn.*. *Hincks*, 'Brit. Mar. Pol.' p. 106, pl. xiii. figs. 1–4. Hincks gives 14 recent and 10 fossil synonyms.
„ sinuosa, *Hassall, Hincks*, p. 109, pl. xiii. figs. 5–8.
„ Johnsoni, *Busk*, *Hincks*, p. 112, pl. xiii. figs. 9–12.
The last species: Shetland; Madeira; Algiers.

In the 'Challenger Report' the family contains the following genera:—

1. Salicornaria, *Cuvier*.
2. Melicerita, *Milne-Edwards*.

Genus 47. Salicornaria, *Cuvier*.

'Zoarium radicate, simple or branched, articulated or continuous; cylindrical, with the cells disposed round an imaginary axis; with or without avicularia. When articulated the internodes are connected by short straight tubes, or with the intervention of a convoluted knot of slender tubules.'—*Chal. Rep.* p. 86.

In the above Report Mr. Busk has devoted nearly five pages to the discussion of moot points of structure in the species of the genus irrespective of very full details of the new forms in the 'Challenger' material. The group is divided into three sections, which will be alluded to presently, and then he remarks that, 'speaking generally, the species of *Salicornaria* . . . may be grouped into those in which the areolation is fundamentally rhomboidal, and those in which it is strictly hexagonal' (*op. cit.* p. 87). After giving the 'Challenger' species I will give the list as furnished by Mr. Busk, in which the two sorts of areolation may be studied. It may be well to note that the closer study of the chitinous parts—given by Mr. Busk in the woodcuts—will afford ample and interesting details when dealing with the new or even the well-known species of this remarkable group. I do not, however, think that the new light thrown upon the 'Challenger' species will be lost or neglected in future researches of students of our British and foreign marine polyzoa.

§ Simplices, *Busk*.

Species in which the zoarium is single or composed of a single segment, &c.

1. Salicornaria clavata, *Busk*, 'Chal. Rep.' pl. xii. fig. 8, and woodcut, p. 88
= Cellaria fistulosa, *Macgillivray*, 'Nat. Hist. Vict.' Decade V. (not *Linn.*)
= C. fistulosa, *var.* australis, *Hincks*, 'Ann. Mag. Nat. Hist.' 5th ser. vol. xiii. p. 368, 1884.

§ β. Articulatæ (α, *tubulatæ*).

Species in which the internodes are connected by elastic or flexible joints, &c.

2. Salicornaria simplex, *Busk*, 'Chal. Rep.' pl. xxxiii. fig. 8, and woodcut, p. 88.

(*β, nodatæ*).

3. Salicornaria variabilis, *Busk*, 'Chal. Rep.' pl. xii. figs. 3, 9, and woodcut, p. 89.
4. „ divaricata, *Busk*, 'Chal. Rep.' p. 90, woodcut only.
5. „ bicornis, *Busk*, 'Chal. Rep.' pl. xxxiii. fig 9, and woodcut, p. 90
   = S. tenuirostris, *var. a*, bicornis, 'Brit. Mus. Cat.' pl. lxiii. fig. 4
   = (?) Cellaria tenuirostris, *Macgillivray*.
6. „ dubia, *Busk*, 'Chal. Rep.' pl. xii. fig. 2, and woodcut, p. 91.
7. „ Malvinensis, *Busk*, 'Chal. Rep.' pl. xii. figs. 1, 5, 7, and woodcuts, p. 91
   = S. Malvinensis, *Busk*, 'Brit. Mus. Cat.'
   = Cellaria *id.*, *Waters*, Bry. S.-W. Vict. 'Quart. Jour. Geol. Soc.' August 1881.
8. „ tenuirostris, *Busk*, 'Chal. Rep.' p. 92, woodcut
   = Salicornaria *id.*, 'Brit. Mus. Cat.'
   = Cellaria *id.*, *Smitt*, 'Florid. Bry.'
9. „ gracilis, *Busk*, 'Chal. Rep.' p. 93, woodcuts, p. 93
   = S. gracilis, *Busk*, 'Brit. Mus. Cat.'
   = S. punctata, *Busk*, 'Voy. of Rattles.'
   = Cellaria gracilis, *Macgillivray*.
   ? „ attenuata, *D'Orb*.
   ? „ tenella, *Lamk*.
   ? „ salicornarides, *Savig.*, 'Egypt.' pl. vi. fig. 7.

§ γ. Inarticulatæ.

10. Salicornaria magnifica, *Busk*, 'Chal. Rep.' pl. xii. figs. 4–6, woodcut, p. 94.

This is the whole of the *Salicornaria* amongst the 'Challenger' material, but on p. 87 of 'Report' Mr. Busk gives the list previously referred to.

§ α. *Areolation rhomboidal, articulation tubular.*

1. Salicornaria farciminodes, *Cuvier*.
2. „ sinuosa, *Haswell*.
3. „ simplex, *Busk* (No. 2 of 'Chal.' list).
4. (?) „ crassa (n. sp.), *Busk*.
5. „ hirsuta, *Kirchenpauer*.

§ β. *Areolation hexagonal, articulation nodular.*

6. Salicornaria variabilis, *Busk* (No. 3 of 'Chal.' list).
7. „ aciculata (n. sp.), *Busk*.
8. „ bicornis, *Busk* (No. 5 of 'Chal.' list).
9. „ dubia, *Busk* (No. 6 of 'Chal.' list).
10. „ Malvinensis, *Busk* (No. 7 of 'Chal.' list).
11. „ tenuirostris, *Busk* (No. 8 of 'Chal.' list).
12. „ Johnsoni, *Busk*.
13. „ „ *var.* gracilis, *Busk*.
14. (?) „ hexagonalis (n. sp.), *Busk*.

§ γ. *Inarticulatæ.*

15. Salicornaria magnifica, *Busk* (No. 10 of 'Chal.' list).

Genus 47. (?) Farcimia, *Pourtalès.*

Smitt, 'Florid. Bryozoa.'
Hincks, 'Ann. Mag. Nat. Hist.' vol. x. 5th ser. 1883.

Zoœcia calcareous, erect, branching; stem and branches composed of segments united by corneous joints. Zoœcia arranged in series round an imaginary axis, with elevated margins and a depressed area, which is more or less covered in with membrane.

'The genus instituted by Pourtalès,' says Mr. Hincks (*op. cit.* p. 199), 'and adopted by Smitt ('Florid. Bryozoa,' Part II. p. 2), includes forms with a Cellarian habit and a Membraniporidan cell.'

1. Farcimia cereus, *Pourtalès.*
2. „ appendiculata, *Hincks* (*op. cit.* 'Annals'), p. 199, pl. vii. fig. 4.
   Locality: Port Phillip Head (*J. B. Wilson*).

The striking feature of the new species are the avicularia. They are remarkable for their size, and in structure they seem to resemble the lateral appendage of *Scrupocellaria.*

Genus 48. Melicerita, *Milne-Edwards.*

Cellaria (sp.), *Waters* (see *Busk* for other synonyms).

'Zoarium compressed, bilaminar, rigid, lobate, ligulate, or foliaceous; articulated or continuous. Zoœcia usually disposed in transverse rows. Surface areolated. Area rhomboid or hexagonal. Orifice sub-central, semicircular, or oblong; border entire, with two articular teeth below and sometimes also above. Operculum corresponding in form to the orifice, supported by a chitinous ring, incomplete above.'—*Chal. Rep.* p. 95.

Mr. Busk says up to the present time the only known species referable to *Melicerita* were two, or perhaps three, fossil forms, viz.:—

1. Melicerita Charlesworthii, *Milne-Edw.*
2. „ angustiloba, *Busk.*
3. (?) „ achates, *D'Orb.* (Lateresehara).

In the 'Challenger Report' two other species are described as new:—

4. Melicerita atlantica, *Busk*, 'Chal. Rep.' pl. xiv. fig. 1, woodcuts, p. 96.
5. „ dubia, *Busk*, 'Chal. Rep.' pl. xxxii. fig. 10.

Family XVI. **Tubucellaridæ**, *Busk*

= Cellaridæ (pars), *D'Orb.*; Salicornariidæ (pars), *Macgil.*
= Porinidæ (pars), *Hincks.*

'Zoarium erect; radicate, composed of cylindrical internodes. Zoœcia disposed round an imaginary axis, convex, distinct, pyriform; peristome

produced, tubular. Surface reticulato-punctate, or simply punctate with or without a simple median pore on the front (often wanting). Avicularia and oœcia.'—*Chal. Rep.*

1. Genus Tubucellaria, *D'Orb.*
2. „ Siphonicytara, *Busk.*

In the family *Porinidæ*, as described by Mr. Hincks, 'Brit. Marine Polyzoa,' four genera were included, viz.:—

1. Genus Porina, *D'Orb.*
2. „ Anarthropora (part), *Smitt.*
3. „ Lagenipora, *Hincks.*
4 „ Celleporella, *Gray.*

In the classification of Mr. Busk only two of these four types are accounted for, and in justice to Mr. Hincks I have allowed species of these genera to precede the Tubucellariadæ, not as a part of Mr. Busk's grouping, but because they are not otherwise accounted for. Miss E. C. Jelly informs me that Lagenipora is far more widely distributed in British seas than was supposed when the original description was drawn up; and in some of his foreign Cheilostomata Mr. Hincks describes a new species of the same genus.

Family XII. Porinidæ, *D'Orb.*

(*Hincks*, 'Brit. Mar. Polyzoa,' p. 226.)

'Zoarium incrusting, or erect and ramified. Zoœcia with a raised tubular or sub-tubular orifice, and frequently a special pore in the front wall.'—*Op. cit.* p. 226.

Genus 51. (?) Lagenipora, *Hincks.*

'Colonies consisting of a number of cells immersed in a common calcareous crust. Zoœcia decumbent, contiguous, lageniform; oral extremity free, tubular, with a terminal orbicular orifice.'—*Op. cit.* p. 235.

1. Lagenipora socialis, *Hincks*, 'Brit. Mar. Pol.' vol. i. p. 235; vol. ii. pl. xxxiv. figs. 7, 8.
„ spinulosa, *Hincks*, 'Polyzoa of Queen Charlotte Island,' 'Annals,' January and March 1884.

Genus 52. (?) Celleporella, *Gray.*

'Zoœcia sub-erect, the anterior extremity tubular and free, with a terminal circular orifice. No special pores. Zoarium (in the British species) incrusting.'—*Brit. Mar. Pol.* p. 413.

1. Celleporella lepraloides, *Norman*, 'Quart. Jour. Mic. Soc.' (n. sp.) viii. p. 222, pl. vii. figs. 4, 5, 'Brit. Mar. Pol.' p. 414, woodcuts.
2. „ pygmea, *Norman*, Shet. Pol. 'Brit. Assoc. Rep.' 1868. 'Brit. Mar. Pol.' p. 415.

The other genera of Hincks's *Porinidæ* will be accounted for further on.

Genus 49. Tubucellaria, *D'Orb.* and *Macgil.*

Tubicellaria, *Heller, Risso, Costa*; Onchopora (sp.), *Busk.*

'Zoarium composed of cylindrical, usually quadriserial, internodes, articulated by flexible tubular peduncles, and arising either dichotomously from the extremity, or irregularly from the sides of the segment from which they spring. Zoœcia pyriform, prolonged, and attenuated downwards, ventricose above, and produced into a tubular peristome, bordered by a very thin septal ridge. A simple circular median pore (often absent) in front, immediately below the tubular peristome. Surface reticulate, scrobiculate, or simply and sparingly punctate.'—*Chal. Rep.*, p. 99.

The genus thus defined includes four known and well-marked forms, which, besides the sculpturing of the surface, possess the simple circular median pore. To these another species, provisionally named, is added by Mr. Busk, and this is sparsely punctured, and there is no trace of a median pore. The species are—

1. Tubucellaria opuntioides, *Pallas.*
2. „ cereoides, *Ell. & Sol.*
3. „ hirsuta, *Lamx.*
4. „ fusiformis, *D'Orb.*
5. „ cæca, *Busk* (provisional).

Of these only 1 and 3 occur in the 'Challenger' collection.

1. Tubucellaria opuntioides, *Pallas*, 'Chal. Rep.' pl. xxiv. fig. 7; pl. xxxvi. fig. 19 (pars).
2. Tubucellaria hirsuta, *Lamx.* 'Chal. Rep.' p. 100, pl. xxxvi. fig. 18.

Genus 50. Siphonicytara, *Busk.*

'Zoarium continuous, radicate, branched; branches alternate, subcylindrical quadriserial, subsecund. Zoœcia completely immersed below, flattened in front. Peristome tubular, extended. A circular median pore below the middle of the front. A large circular orifice (avicularian ?) near the top of most of the lateral zoœcia behind.'—*Chal. Rep.*, p. 101.

Siphonicytara serrulata, *Busk*, 'Chal. Rep.' pl. xv. fig. 2.

(For Genera 51 ? Lagenipora, *Hincks*; and 52 ? Celleporella, *Gray*, see *ante*, p. 553. For Genera 53 ? Rhyncopora, *Hincks*; 54 ? Schizotheca, *Hincks*; and 54*, Mastigophora, *Hincks*, see p. 101.)

Family XVII. **Onchoporidæ**, *Busk.*

'Zoarium flexible, continuous, branched or lobate, ligulate or foliaceous, then unilaminar. Zoœcia urceolate, ventricose. Orifice semicircular, with a straight entire lower lip. On the front, close below the orifice, a lunate fringed pore, and on each side an oblong or circular perforated disc, with a raised border.'—*Chal. Rep.*, p. 102.

Mr. Busk justifies himself in separating this small group from the genus Microporella of Hincks, although a number of other forms possess a similar lunate pore combined with a similarly shaped orifice. It appears to me that Mr. Busk is perfectly right in the course he has taken; but great credit, notwithstanding the separation, is due both to Mr. Hincks and to Mr. Waters on account of the calmly consistent manner in which species of the genus Microporella have been worked up.[1]

[1] Since the whole of this report was in the hands of the printer Mr. A. W. Waters's

Genus Onchopora, *Busk.*
„ Onchoporella, *Busk.*

Genus 55. Onchopora, *Busk*
= Carbasea (pars), *Busk*
= Malakosaria, *Goldstein.*

'Zoarium dichotomously branched, cylindrical, quadriserial.'—*Chal. Rep.*, p. 103.

Family XVIII. **Reteporidæ**, *Smitt*

= Reteporidæ, *Smitt*, 1867; *Hincks*, 1879.

Escharidæ (pars), *D'Orb*, 1851; *Hincks*, 1880; *Smitt*, 1872; 'Brit. Mus. Cat.' 1852, *Busk*, 'Crag Polyzoa,' 1859; *Macgillivray*, &c.

'Zoarium calcareous, erect, fixed; foliaceous and fenestrate, unilaminar, or reticulately or freely ramose in one plane. Zoœcia secund.' —*Chal. Rep.*, p. 104.

1. Genus Retepora, *Imperato*, 4 sections.
2. „ Reteporella, *Busk* (sub-genus, *Busk*).
3. „ Turritigera, *Busk.*

Genus 57. Retepora, *Imperato*

= Retepora (pars), *Lamx.*, *Blainv.* 'Brit. Mus. Cat.'
Eschara (pars), *Smitt*; Millepora (pars), *Linn.*, *Pallas.*, *Ellis.*

'Zoarium reticulate, formed of flexuose, anastomosing branches, or fenestrate; erect, springing with a calcareous stem, rarely from an incrusting or spreading base. Zoœcia disposed on one aspect only, usually deeply immersed, except on the sides of the branches or trabeculæ.

paper ('Cheilostomatous Bryozoa' from Aldinga, &c. *Quart. Jour. Geol. Soc.* Aug. 1885) has come to hand. I find that he takes exception to, and freely criticises Mr. Busk's arrangement in his prefatory remarks. I think it will be better to refer the student to the paper itself, rather than point out all the moot-points raised by Mr. Waters.

Primary orifice sub-orbicular or semicircular; border entire. Afterwards the peristome becomes much raised and multiform, usually fissured in the middle or one side in front, the fissure often becoming a sub-oral pore by the meeting of the upper angles. Very often a small avicularium on one of the angles, which is also frequently developed into a labial or pre-oral rostrum. Usually numerous adventitious avicularia on one or both aspects of the zoarium.'—*Chal. Rep.*, pp. 105, 106.

I suppose that there are not among the whole of the recent Polyzoa two more difficult groups to master the details of than the *Reteporæ* and the *Celleporæ*. I know too well that this is painfully true of the fossil species that have been placed in either of these respective groups. My early dissent from the supposed identity of the Palæozoic forms with recent species was very early expressed in my crude articles in 'Science Gossip,' and later on in the earlier of my 'British Association Reports' (Carboniferous, 1880, and Silurian, 1881); and it must be remembered that at this time very little attention had been paid to the inner structure of either fossil or recent forms, so that even up to a very recent date Palæozoic species, which were fenestrated by the inosculation of branches, were indifferently placed among the *Reteporidæ* as then understood. Within the last six or seven years a very great advance has been made in the study of parts of the zoarium of fossil species of Polyzoa; and the remark is especially applicable to the study of parts of the zoarium in recent forms of several groups of Polyzoa. One of the comparatively recent additions to our knowledge of parts of the zoaria of species is that of the Rossenplatten (communicative pores of Hincks), through which the endosarcal cords passed from cell to cell. This, though eminently available for the classification of recent species, is not so available for the more minute study of fossil species. Another more recent addition to our knowledge of the chitinous appendages of species was made by Mr. A. W. Waters in a communication to the Geological Section of the Manchester Literary and Philosophical Society, and ultimately published in their 'Proceedings' (vol. xviii. No. 2, Sess. 1878–9). The paper referred to was one on 'The Use of the Opercula in the Determination of the cheilostomatous Bryozoa.' Mr. Waters figures and describes thirty-seven species of operculæ, all magnified eighty-five times, and his specimens were selected from a much larger group of forms than those enumerated. This paper seems to have been entirely unknown to Mr. Busk until after the drawing up of the Descriptive Catalogue of the Species of *Cellepora* collected in the 'Challenger' Expedition ('Linn. Soc. Journ. Zoology,' vol. xv. 1881?). In a 'supplementary note respecting the use to be made of the chitinous organs in the Cheilostomata, &c.' ('Linn. Soc. Jour.' vol. xv.), Mr. Busk speaks his regret, acknowledges the value of the paper by Mr. Waters, and then says (*loc. cit.* p. 357): 'But having since devoted much attention to this point, and examined the characters not only of the operculum, as suggested by Mr. Waters, but also, in addition, those of the other chitinous elements of the skeleton in between sixty and seventy species of *Celleporæ*, as well as in numerous species of *Reteporæ* and *Salicornariadæ*, both groups in which the determination of species is often attended with considerable difficulty and uncertainty, I have become convinced that the characters derived from the chitinous organs will be found of the greatest possible utility, and at the same time capable of being employed with the utmost facility and precision.' The new knowledge derived from the study of the chitinous parts of recent

Polyzoa is one of the charms of the 'Challenger Report'; and Mr. Busk, in his admirable drawings and woodcuts, gives ample material for the beginning of a new speciality in the study of fossil and recent Polyzoa. Previous to the publication of the 'Challenger Report,' however, Mr. P. H. Macgillivray published a paper in the 'Proceed. Roy. Soc. Victoria,' Aug. 1883, on the chitinous parts of Polyzoa, and he remarks similarly of the value of the operculæ as previously mentioned by Mr. A. W. Waters.

Independent, however, of these labours on the chitinous appendages, Mr. Hincks devoted his attention to special groups of Polyzoa previous to the publication of the 'Brit. Marine Polyzoa'; and one of the most elaborate of these published papers is his Notes on the Genus *Retepora* ('Ann. Mag. Nat. Hist.' 5th ser. vol. i. 1878). In this paper is enumerated all the recent species described up to that time. This list is as follows:—

1. Retepora phœnicea, *Busk* = (?) R. indica, *D'Orb.*
2. ,, monilifera, *Macgil.*
3. ,, porcellana, *Macgil.*
4. ,, granulata, *Macgil.*
5. ,, fissa, *Macgil.*
6. ,, versipalma, *D'Blainv.* (? sp.)
7. ,, marsupiata, *Smitt* = R. cellulosa, *var.*
8. ,, reticulata, *Pourtalès* = (?) R. Beaniana, *var.*
9. ,, Wallichiana, *Busk & Hincks* = R. elongata, *Smitt.*
10. ,, Edwardsii = (?) R. cellulosa.
11. ,, Beaniana, *King.*
12. ,, cellulosa, *authors.*
13. ,, Couchii, *Hincks.*
14. ,, prætenuis, *Hincks.*
15. ,, plana, *Hincks.*
16. ,, tessellata, *Hincks.*
17. ,, robusta, *Hincks* = (?) R. porcellana, *Macgil.*

To which may be added, says Mr. Busk—

18. Retepora bi-avicularia, *Smitt* = R. Beaniana, *var.*
19. ,, altisulcata, *Ridley.*
20. ,, microthyris, *Busk* (MS.)
21. ,, umbonata, *Macgil.*, *var.* of R. monilifera.
22. ,, sinuata, *Macgil.* ,, ,,
23. ,, lunata, *Macgil.* (?) ,, ,,
24. ,, acutirostra, *Macgil.* (?) ,,
25. ,, munita, *Hincks* (?) ,, ,,
27. ,, formosa, *Macgil.*
28. ,, serrata, *Macgil.*
29. ,, aurantiaca, *Macgil.*
30. ,, laxa, *Hincks* (? *var.* porcellana, *Macgil.*)
31. ,, avicularis, *Macgil.*

To which must now be added the 'Challenger' species, bringing up the described or catalogued number to about fifty or sixty species.

§ *a. Reticulatæ.*

32. Retepora apiculata, *Busk*, 'Chal. Rep.' pl. xxv. fig. 6, woodcut, chitinous appendages, p. 108.

33. Retepora producta, *Busk*, 'Chal. Rep.' pl. xxv. fig. 7, woodcut, p. 108.
34. „ denticulata, *Busk*, 'Chal. Rep.' pl. xxvi. fig. 1, woodcut, p. 109.

§ β. *Fenestratæ.*

Zoaria foliaceous, fenestrate.

35. Retepora Imperati, *Busk* (MS.), 'Chal. Rep.' pl. xxvi. fig. 9
= R. eschara marina, *Imperato*
= R. cellulosa, *a* (pars), *Auctt.*
= Millepora foraminosa, *Ell. & Sol.*
= R. elongata, *D'Orb. & Smitt, var.*

Mr. Busk gives a very elaborate account of these species, which occupies about two and a half pages of the Report, together with woodcut (fig. 19) of the chitinous parts of *R. imperati* and *R. elongata*, p. 111.

36. „ tessellata, *Hincks*, 'Chal. Rep.' pl. xxvii. fig. 8 (*Hincks*), 'Ann. Mag. Nat. Hist.' 1878.
37. „ *var. α*, cæspitosa, *Busk*, 'Chal. Rep.' pl. xxvii. fig. 6, woodcut, fig. 20, p. 113
=(?) R. tessellata, *Hincks.*
38. „ *var. β*, pubens, *Busk*, 'Chal. Rep.' pl. xxviii. fig. 3, woodcut, fig. 21.

§§. *Oœcium, with a vertical fissure in front.*

39. Retepora gigantea, *Busk*, 'Chal. Rep.' pl. xxvi. fig. 7, woodcut, fig. 22, p. 114.
40. „ lata, *Busk*, 'Chal. Rep.' pl. xxvii. fig. 1, woodcut, fig. 23, p. 115.
41. „ crassa, *Busk*, 'Chal. Rep.' pl. xxvi. fig. 10; pl. xxvii. fig. 3, woodcut, fig. 24, p. 115.
42. „ atlantica, *Busk* (?), 'Chal. Rep.' pl. xxviii. fig. 1, woodcut, fig. 25, p. 116.
= (?) R. cellulosa *var.* marsupiata, *Smitt.*

§§. *Oœcium with a trifoliate stigma in front.*[1]

43. Retepora victoriensis, *Busk*, 'Chal. Rep.' pl. xxvii. fig. 7, woodcut, fig. 26, p. 117
= (?) R. carinata, *Macgil.*
44. „ *Var.* japonica, 'Chal. Rep.' p. 118, woodcut, fig. 27.
45. „ simplex, *Busk*, 'Chal. Rep.' pl. xxviii. fig. 4, woodcut, fig. 28, p. 118.
46. „ hirsuta, *Busk*, 'Chal. Rep.' pl. xxvi. fig. 4, woodcut, fig. 29, p. 119
= (?) R. monilifera, *Macgil.*, *Hincks.*
47. „ mucronata, *Busk*, 'Chal. Rep.' pl. xxvi. fig. 6.
48. „ contortuplicata, *Busk*, 'Chal. Rep.' pl. xxvi. fig. 2, woodcut, fig. 30, p. 120.
49. „ cavernosa, *Busk*, 'Chal. Rep.' pl. xxvi. fig. 8, woodcut, p. 121, fig. 31.

[1] Respecting this peculiar stigma in front Mr. Busk (p. 117) adds in a note a few particulars about the original remarks of Macgillivray, made more than twenty years ago, but which seem to have attracted but little attention by authors.

50. Retepora tubulata, *Busk*, 'Chal. Rep. pl. xxviii. fig. 2, woodcut, p. 122, fig. 32.
51. " columnifera, *Busk*, 'Chal. Rep.' pl. xxvi. fig. 5, woodcut, p. 122, fig. 33.
52. " Philippinensis, *Busk*, 'Chal. Rep.' pl. xxvii. fig. 5.
53. " Phœnicea, *Busk*, 'Chal. Rep.' p. 124, woodcut, and 'Brit. Mus. Cat.'

§§ 4. *Oœcia inconspicuous or unknown.*

54. Retepora delicatula, *Busk*, 'Chal. Rep.' pl. xxvi. fig. 3, woodcut, fig. 35, p. 124.
55. " margaritacea, *Busk*, 'Chal. Rep.' pl. xxvii. fig. 2, woodcut, p. 125.
56. " Jacksoniensis, *Busk*, 'Chal. Rep.' pl. xxvii. fig. 4, woodcut, p. 125.
57. " Magellensis, *Busk*, 'Chal. Rep.' pl. xxxvi. fig. 20.

Under the fenestrate section of the *Reteporidæ* Mr. Busk ('Challenger Report,' p. 104, note) says that Macgillivray's species, PETRALIA UNDATA, may be included in a sub-genus. I have a specimen of Macgillivray's species from Port Phillip Heads, but I have not Macgillivray's description. It is a very peculiar fenestrated form, with cells on one side only, and if it be included among the RETEPORIDÆ, it must be on account of its 'foliaceous and unilaminar character.' The cells and also the ovicells have a very distinctive feature.

Sub-genus 58. Reteporella, *Busk.*

'Characters those of *Retepora*, but the branches free in one plane.' *Chal. Rep.* p. 126.

This appears to me to be rather an important separation, because there are many fossil species of *Retepora* which are neither fenestrate nor reticulate, but which have all the characters of ordinary species. These may now be placed in this sub-genus, to the great advantage of the student of fossil forms.

1. Reteporella flabellata, *Busk*, 'Chal. Rep.' pl. xxv. fig. 5, woodcut, p. 126, fig. 38.
2. " myriozoides, *Busk*, 'Chal. Rep.' pl. xxiv. fig. 2.

Genus 59. Turritigera, *Busk.*

'Zoarium ramose, arising from a calcareous expansion, incrusting foreign bodies, having the openings of the zoœcia usually on one side only. Zoœcia ventricose or flask-shaped, much produced and sub-tubular above, with several conical or columnar avicularian processes on the peristome.'—*Chal. Rep.* p. 129.

Turritigera stellata, *Busk*, 'Chal. Rep.' pl. xxiv. fig. 1.

Mr. Busk very truly remarks that this 'form appears to be more nearly allied to Retepora than to any other generic group, but the very curious conformation of the oral portion and aperture, and its other peculiarities, seem to justify its being considered as generically distinct.'

One can hardly help speaking of the very admirable way in which Mr. Busk has dealt with this remarkable group. His descriptions and

diagnoses occupy about twenty-six pages, two and a half of which number are devoted to the geographical and bathymetrical range of species. This part of the Report, however, will appear in its proper place further on.

In justice to Mr. Hincks and to Mr. A. W. Waters, after the very full remarks on the species by Mr. Busk, it would appear to me very unwise to pass over the labours of these respected authors.

Notes on the genus Retepora, with descriptions of new species. By the Rev. Thomas Hincks, 'Ann. Mag. Nat. Hist.' May 1878.

Mr. Hincks begins this paper by giving a list of previously described species from different seas by different authors. From Australia five species; from the South seas, one; from India, one; from Florida, three; from the Arctic and North seas, two; and from the British and Mediterranean seas, two: after which he proceeds with a very full description of new or little known species.

Genus Retepora, *Lamarck.*

α. *With an oral fissure.*

1. Retepora Couchii, *Hincks* (*op. cit.* p. 355, pl. xviii. figs. 1–6)
   = Retepora Beaniana, *Hincks*, 'Dev. and Cornwall Cat.'
   = „ cellulosa, *var.* Beaniana, *Manzoni.*
2. „ prætenuis, *Hincks* (*op. cit.* p. 356, pl. xix. figs. 6, 8).

β. *Without an oral fissure.*

3. „ plana, *Hincks* (*op. cit.* p. 358, pl. xviii. figs. 7, 8).
4. „ tessellata, *Hincks* (*op. cit.* p. 358, pl. xix. figs. 9–12).
5. „ robusta, *Hincks* (*op. cit.* p. 359, pl. xviii. figs. 9–10).

Mr. Hincks says that the following species have already been described,[1] but he ventures to give a fuller diagnosis:—

6. Retepora monilifera, Macgil. (*Hincks, op. cit.* p. 360, pl. xix. figs. 1–5).
7. „ Phœnicea, *Busk*, 'Cat. Mar. Pol.'
8. „ granulata, Macgil. (*Hincks, op. cit.* p. 363, pl. xix. figs. 13–15).
9. „ cellulosa, Smitt (*Hincks, op. cit.* p. 364).

Family XIX. **Cribrilinidæ,** *Hincks.*

'Brit. Mar. Pol.' vol. i. p. 182; 'Chal. Rep.' p. 130.

Mr. Hincks's description of this family group is as follows:—

'Zoarium adnate, forming an indefinite crust, or erect. Zoœcia having the front wall more or less fissured, or traversed by radiating furrows.' Mr. Busk, however, adds to his description other characters, and slightly modifies the remarks of Mr. Hincks:—

'Zoarium crustaceous, or adnate (lepralian), or erect and unilaminar (hemischaran). Zoœcia, front with transverse or radiating fissures or rows of punctures without fissures. Mouth simple, sub-orbicular, sometimes mucronate or semicircular; with or without a median sub-oral pore.'—*Chal. Rep.* p. 130.

[1] *Notes on the Cheilostomatous Polyzoa of Victoria and other parts of Australia* (P. H. Macgillivray), 'Trans. Phil. Inst. Victoria,' vol. iv. 1860, p. 168, &c.

Genus 60. Cribrilina, *Gray*.

Cribrilina, *Gray*, *Hincks*, *Smitt*, *Busk*, 'Chal. Rep.'
Lepralia (pars), *Busk*, 'Brit. Mus. Cat.' *Johnst.*
Repteschareila, *D'Orbigny*, 'Pal. Franc. Tert. Cret.'
Escharipora, *Smitt*, 1867.

'Front of cells fissured, or simply punctured in regular or transverse rows.'—*Busk*, 'Chal. Rep.'

In the 'British Marine Polyzoa' Mr. Hincks describes the following species. Except in some few instances I have not thought it wise to reproduce the whole of the synonyms given by authors, as a very full list was appended to a previous list in the Fifth Report on Fossil Polyzoa, 'Brit. Assoc. Rep.' and is furnished (from Busk and Hincks) in the introductory part of the present Report.

1. Cribrilina radiata *Moll.* (*op. cit.* pl. xxv. 1–9).
   Var. α, Antrim, deep water.
   Var. β, (*op. cit.* pl. xxv. fig. 4).
   Var. γ, tenuirostris, Madeira.
2. ,, punctata, *Hassall* (*op. cit.* pl. xxvi. figs. 1–4; pl. xxiv. fig. 3).
   Var. α, with a central umbo.
3. ,, annulata, *Fabric.* (*op. cit.* pl. xxv. figs. 11, 12).
4. ,, figularis, *Johnst.* (*op. cit.* pl. xxvi. figs. 5–7).
   Var. α, fissa.
5. ,, Gattyæ, *Busk* (*op. cit.* pl. xxv. fig. 10).
   Var. α, Hastings, *Miss E. C. Jelly.*

Many of these species have a wide geographical range both around our coast, some of them reaching far north. The varieties are very local.

Only one genus—*Cribrilina*—is at present admitted by Mr. Busk in his classified list, but in the classification of Mr. Hincks another genus, Membraniporella, *Smitt*, forms part of Cribrilinidæ, *Hincks*. In the definition, however, of Mr. Busk, the *hemischaran* forms of Mr. Hincks are included.

In the 'Challenger Report' the following species are described in several sections by Mr. Busk.

§ α. *Front fissured.* §§ 1. *Adnate* (*lepralian*).

1. Cribrilina radiata, *Moll.*, 'Chal. Rep.' p. 131. Found only in two stations, 75 and 135 A.
2. ,, latimarginata, *Busk*, 'Chal. Rep.' pl. xxii. fig. 10. One station only 320 on dead coral. In his remarks Mr. Busk says that Reuss describes and figures in his 'Palæon. Stud.,' under the name of *Celleporaria radiata*, a form in so many respects closely resembling his *C. latimarginata*. In other respects there is a difference.

§§ 2. *Free, erect or decumbent* (*hemischaran*).

3. Cribrilina philomela, *Busk*, 'Chal. Rep.' pl. xvii. fig. 6
   = (?) C. speciosa, *Hincks*, 'Ann. Mag. Nat. Hist.' 1881
   = (?) Repteschareila inæqualis, *D'Orb.*
   Var. α, adnata, *Busk*, 'Chal. Rep.' pl. xxii. fig. 7.
   (?) C. figularis, *var. Hincks.*

§ *β*. *Front with punctures in more or less distinct transverse rows.*

4. Cribrilina labrosa, *Busk.*
   Var. α, fragilis, *Busk*, 'Chal. Rep.' pl. xix. fig. 4.
5. „ monoceros, *Busk*, 'Chal. Rep.' pl. xix. fig. 8
   = (?) Lepralia larvalis, *Busk*, 'Brit. Mus. Cat.'

It might be a question, says Mr. Busk, whether the numerous forms that would come under § *β* should not be considered generically distinct from the fissured ones, p. 134.

Leaving this question to be settled by special workers on recent forms of Polyzoa, I will now give as full a list as possible of additions to the Cribrilinidæ by Mr. Hincks since the publication of the 'British Marine Polyzoa.' In his Contributions, 'Annals,' July 1880. After describing the Madeira species, C. radiata, *Moll.*, in J. Y. Johnson's material, Mr. Hincks said that, besides the British species, he only knew three others that could be referred to the genus Cribrilina.

Cribrilina cribrosa, *Heller*
= Lepralia cribrosa, *Heller.*
„ Jaubertii, *Audouin*
= Flustra Jaubertii, *Aud.*
„ Floridana, *Smitt.*

In his paper on the Polyzoa from Bass's Straits (Captain Warren's collection, now in the Liverpool Free Museum) four species are described, two of which are new. ('Annals' and 'Mag. Nat. Hist.' July 1881).

Cribrilina ferox, *Macgillivray.*
„ tubifera, *Hincks* (*op. cit.* pl. i. fig. 7).
„ speciosa, *Hincks* (*op. cit.* pl. i. fig. 8).
„ (?) monoceros, *Macgil.* (*op. cit.* pl. iii. fig. 6).

Mr. Hincks has placed under Macgillivray's name the Bass's Straits form, but only doubtfully. It is not Busk's *C. monoceros*, but it is allied to *C. punctata.*

In the papers on the Polyzoa of Queen Charlotte Islands, two other species are described and illustrated:—

Cribrilina furcata, *Hincks*, 'Ann. Mag. Nat. Hist.' Dec. 1882, pl. xx. fig. 5.
„ hippocrepis, *Hincks* (*op. cit.* pl. xx. fig. 6, 6*a*).
Loc.: Cumshewa; Houston Stewart Channel, abundant.
„ radiata, form innominata.
Form with vibraculoid setæ not uncommon (*op. cit.*) Jan. 1883.

Mr. Hincks says that some beautiful varieties of this variable species occur in the material from Queen Charlotte Islands, 'and the form which bears vibraculoid setæ is especially remarkable for richness of sculpture and delicacy of structure.'

See also the preliminary paper on the New Species in the Queen Charlotte Islands Collection, 'Ann. Mag. Nat. Hist.' Sept. 1882, pp. 248–256. No plates.

Genus 61. Membraniporella (*pars*), *Smitt.*

See Hincks, 'Brit. Mar. Polyzoa,' p. 199.
'Florid. Bryozoa,' *Smitt*, Part II, p. 10.

'Zoarium incrusting, or rising into free, foliaceous expansions, with a single layer of cells (hemischaran) (?) *Busk.* Zoœcia closed in front by a number of flattened calcareous ribs more or less consolidated.'—*Brit. Mar. Polyzoa*, p. 199.

1. Membraniporella nitida, *Johnst.*, *op. cit.* pl. xxvii. figs. 1–8.
2. " melolontha, *Busk*, *op. cit.* pl. xxvii. figs. 9, 10.

Family XX. **Microporellidæ.**

Microporellidæ (*pars*), *Hincks*, 'Brit. Mar. Pol,' p. 204.
This family as established by Mr. Hincks ('Brit. Mar. Pol.') embraced three genera:—

Genus Microporella, *Hincks.*
" Diporula, *Hincks.*
" Chorizopora, *Hincks.*

In the 'Challenger Report' (p. 134) Mr. Busk has modified the definition of Mr. Hincks for the purpose of 'limiting it to such Escharine forms as have a true lunate pore. Consequently, as here understood, it corresponds with Professor Smitt's genus *Porrelina* ("Florid. Bryoz." p. 27).' The genus *Chorizopora*, Hincks, is relegated to the next family, Escharidæ, and *Diporula*, Hincks, is not accounted for in the 'Challenger Report.'

'Mouth semicircular or coarctate, with an entire straight lower border; a lunate fimbriated median pore. Zoarium erect and bilaminar, or crustaceous and adnate.'—*Chal. Rep.* p. 134.

§ α. *Erect, bilaminar.*

Genus Flustramorpha, *Gray.*

§ β. *Crustaceous.*

Genus Microporella, *Hincks.*

§ α. *Erect, bilaminar.*

Genus 62. Flustramorpha, *Gray*

= Mastigophora (*pars*), *Hincks.* (See p. 101.)

'Zoarium erect, radicate, bilaminar, composed of irregular lobes, bordered and loosely interconnected by chitinous tubes; mouth coarctate; a lateral pouch-like vibracularium.'—*Chal. Rep.* p. 135.

1. Flustramorpha marginata, *Krauss* (sp.), 'Chal. Rep.' pl. xx. fig. 8, woodcut, p. 135
   = Flustra marginata, *Krauss*
   = Flustramorpha marginata, *Gray.*
2. " hastigera, *Busk*, 'Chal. Rep.' pl. xxi. fig. 7, woodcut, p. 136
   = (?) Porellina ciliata, *Smitt.*

In the Report, p. 136, Mr. Busk indicates other species as belonging to this group, but these are not in the 'Challenger' collection.

3. Flustramorpha flabellaris, *Busk*.
4. „ patagonica, *Busk* (MS. ?)

Genus 63. Microporella, *Hincks* (*Busk* ?).

'Zoarium erect and bilaminar, or incrusting and adnate. Mouth semicircular, with a straight entire lower border, with or without oral spines. An aviculario-vibracular organ on one side of the front, with the mandible forked at the base, or unarmed.'—*Chal. Rep.* p. 137.

1. Microporella personata, *Busk*, (sp.), 'Chal. Rep.' p. 137, woodcut
   = Lepralia personata, *Busk*
   = Microporella ciliata, *var.*, *Hincks*.
2. „ Malussi, *Aud.*, 'Chal. Rep.' p. 137.
3. „ ciliata, *Pallas*, (sp.), 'Chal. Rep.' p. 138.

These are the whole of the *Microporella* given by Mr. Busk in the 'Challenger Report.' As Mr. Hincks has, however, added to the list considerably since the publication of the 'British Marine Polyzoa,' I add the whole to the above without abridgment. As Mr. Busk's estimate of some of his own species, formerly described in the 'British Museum Catalogue,' differs from that of Mr. Hincks, it will be far better for the student of Marine Polyzoa to compare one author with the other before giving a decision either way. It is very certain that some at least of the species of Mr. Hincks will have to be turned over to other genera.

Genus Microporella, *Hincks*.

'British Marine Polyzoa,' vol. i. p. 204, which see for synonyms.

'Zoarium incrusting. Zoœcia with a semicircular aperture, the lower margin entire, and a semi-lunate or circular pore below it.'—*Op. cit.* p. 204.

'We do not know,' says Mr. Hincks, 'the physiological import of the definitely shaped opening in the front wall of the cell, which belongs to this genus. But the character, which is constant, may fairly be accounted of considerable importance, and, taken in combination with the form of the aperture, is a good diagnostic mark.'

1. Microporella ciliata, *Pallas*, *Hincks*, *op. cit.* p. 206, pl. xxviii. figs. 1–8.
   „ *Var. α*, personata, p. 207
   = Lepralia personata, *Busk*.
2. „ Malusii, *Aud.*, *op. cit.* p. 211, pl. xxviii. figs. 9–11; pl. xxix. fig. 12.
   Var. α, thyreophora, p. 212
   = Lepralia thyreophora, *Busk*.
3. „ impressa, *Aud.*, *Hincks*, *op. cit.* p. 214, pl. xxvi. figs. 9–11; pl. xxix. figs. 10, 11.
   Var. α, bimucronata, *Moll.*
   Var. cornuta, *Busk*.
   Var. β, glabra. *Aud.*
   „ *γ*, pyriformis, *Busk*.
4. „ violacea, *Johnst.*, *op. cit.* p. 216, pl. xxx. figs. 1–4.
   Var. β, plagiopora, *Busk*. Crag form.

These are the British species given by Mr. Hincks. The whole have a wide geographical range—and their range in time is also great—but principally Tertiary.

In his paper on the Madeira species, 'Ann. Mag. Nat. Hist.' July 1880, Mr. Hincks adds to the list—

5. Microporella decorata, *Reuss* (near ally of M. violacea), and suggests that the following species should be included in the list:—

Lepralia californica, *Busk.*
,, personata, *Busk.*
,, bicristata, *Busk.*
,, diadema, *Macgil.*
,, ceramia, *Macgil.*

6. Microporella ciliata, form vibraculifera, *Hincks*, Polyzoa Queen Charlotte Is. 'Annals,' Jan. 1883, pl. xvii. fig. 2.
7. ,, form, umbonata, *op. cit.* pl. xvii. fig. 1.
8. ,, ,, californica, *op. cit.* pl. xvii. fig. 3 =Lepralia *id.*, *Busk*, Quart. Jour. Mic. Soc. 1850. p. 310
9. ,, diadema, *Macgil.*, Polyzoa Bass's Straits.
10. ,, fuegensis, *Busk*, 'Annals,' May 1884 Tierra del Fuego.
11. ,, mucronata, *Macgil.*, Pol. Bass's Straits. Very abundant. This species belongs to the same section of the genus as our M. violacea = Eschara mucronata, *Macgil.*
12. ,, fissa, *Hincks*, 'Ann. Mag. Nat. Hist.' Nov. 1880, 5th ser. vol. vi. p. 381, pl. xvii. fig. 4. *Loc.*: Indian Ocean.

To the description of the above Mr. Hincks adds another brief list of *Microporella* :—

13. Microporella coronata, *Audouin* = Flustra *id.*, *Aud.*
14. ,, marsupiata, *Busk* = Lepralia *id.*, *Busk.*
15. ,, stellata, *Verrill* = Porellina *id.*, *Verrill.*

In his paper on the Polyzoa of New Zealand and Australia ('Annals,' March 1885), Mr. Hincks gives the following:—

Microporella Malusii, *Aud.*
16. ,, form disjuncta, *Hincks*, pl. vii. fig. 4. New Zealand.
9. ,, diadema, *Macgil.*
17. form angustipora, *Hincks*, pl. viii. fig. 3.

And to the above the following in all probability may be added:—

18. Microporella bicristata, *Busk* = Lepralia *id.*
19. ,, ceremia, *Macgillivray* = Lepralia *id.*
20. ,, serrulata, *Smitt* = Porina *id.*, *Smitt.*
21. ,, sub-sulcata, *Smitt* = Porina *id.*, *Smitt.*

Family **Monoporellidæ**, *Hincks.*

Genus Monoporella, *Hincks.*

'Zoœcia destitute of a membranous area or aperture, and of raised margins; orifice arched above, with the lower lip entire; no special pores.' *Hincks*, 'Annals.'

Originally Mr. Hincks founded the genus *Monoporella* for species of the *Microporellidian* orifice, but destitute of the median pore, which is so striking a character of the genus *Microporella*. Subsequently the author arranged the few known recent forms under the family name given above. Mr. Waters adopted the name—provisionally—for the fossil species which are given in the fifth Report on Fossil Polyzoa (*mihi*). As yet we have hardly material enough for a full study of the type. The genus is not given by Mr. Busk in his 'Challenger Report.'

1. Monoporella nodulifera, *Hincks*, Polyzoa from Bass's Straits, 'Liverpool Address,' April 1881.
2. „ lepida, *Hincks* (*op. cit.* April 1881).
3. „ albicans, *Hincks*, 'Ann. Mag. Nat. Hist.' Feb. 1882, pl. v. figs. 5–5*b*. *Loc.*: Singapore or Philippines.
4. „ brunnea, *Hincks*, 'Ann. Mag. Nat. Hist.' June 1883, pl. xviii. fig. 4. *Loc.*: Queen Charlotte Islands.

Family **Cyclicoporidæ**, *Hincks*.

'Ann. Mag. Nat. Hist.' October 1884.

Zoœcia having the front wall wholly calcified and destitute of raised margins or depressed area, with a more or less orbicular orifice.

Genus Cyclicopora, *Hincks*.

'Zoœcia with a perfectly simple orifice, more or less orbicular. Zoarium incrusting.'—*Ibid.* p. 279.

Cyclicopora longipora, *Macgil.* (sp.) = Lepralia *id.*
= C. prælonga, *Hincks*, 'Annals,' October 1884, p. 279, pl. ix. fig. 7. *Loc.*: Port Phillip Heads, *J. B. Wilson.*

In the *Escharidæ* Mr. Busk includes no fewer than fourteen genera, and as the family partly supersedes the *Myriozoidæ* of Smitt and Hincks, the following genera are left out in the classification of Mr. Busk in the 'Challenger Report.' They will be reported upon when I have concluded the family arrangement as given in the 'Challenger' monograph.

Genus Umbonula, *Hincks*.
„ Palmicellaria, *Alder*.
„ Rhynchopora, *Hincks*.
„ Schizotheca, *Hincks*.
„ Phylactella (part), *Hincks*.

Family XXI. **Escharidæ**.

'Challenger Report,' *Busk*, p. 138.

Escharidæ (*pars*), *Johnston*, *D'Orb.*, *Busk*, *Smitt*, *Hincks*, &c.
Myriozoidæ (*pars*), *Smitt*, *Hincks*.

'Zoarium calcareous, radicate or fixed; erect, uni- or bi-laminar, foliaceous or ramose, or crustaceous, loosely attached or adnate. Zoœcia urceolate, front entirely calcified.'—*Busk*, 'Chal. Rep.' p. 138.

1. Genus Eschara, *Pallas.*
2. ,, Lepralia, *Johnston.*
3. ,, Chorizopora, *Hincks.*
4. ,, Porella, *Gray.*
5. ,, Escharoides, *Smitt.*
6. ,, Smittia, *Hincks.*
7. ,, Mucronella, *Hincks.*
8. ,, Aspidostoma, *Hincks.*
9. ,, Schizoporella, *Hincks.*
10. ,, Gephyrophora, *Busk.*
11. ,, Myriozoum, *Donati.*
12. ,, Haswellia, *Busk.*
13. ,, Tessaradoma, *Norman.*
14. ,, Gemellipora, *Smitt.*

§ 1. *Lower lip of primary orifice entire.*

§§ *a. Erect, bilaminar.*

Genus 64. Eschara, *Pallas.*

Cellaria (*pars*), *Reuss*; Acropora (*pars*), *Reuss*; Lepralia (*pars*), *Hincks, Smitt.*

'Zoarium erect (sometimes decurrent); foliaceous or ramose, compressed, bilaminar.'—*Chal. Rep.* p. 141.

1. Eschara elegantula, *D'Orb.*, 'Chal. Rep.' pl. xx. fig. 6
= E. saccata, *Busk*, 'Ann. Mag. Nat. Hist.' 1856.
2. ,, gracilis, *Lamk.*, 'Chal. Rep.' pl. xxi. fig. 6
= Cellaria and Acropora coronata, *Reuss*
= Eschara Buskii, *Tenison Woods.*
No *Eschara* are described by Mr. Hincks in his 'British Marine Polyzoa'; and, so far as I am aware, only one species has been added to the list in his various publications since the issue of that work.
3. ,, glabra, *Hincks*, Polyzoa from Barrent's Sea, 'Annals,' Oct. 1880, p. 281, pl. xv. fig. 6.
4. ,, perpusilla, *Busk*, 'Linn. Soc. Jour. Zool.' vol. xv. 1880, pl. xiii. fig. 5. *Loc.*: Arctic Sea.
Associated with this species in the collection of Mr. Busk as described in the above paper is Eschara elegantula, *D'Orb.*

§§ *β. Crustaceous, unilaminar.*

Genus 65. Lepralia, *Johnston.*

Lepralia, *Hincks, Smitt* (*pars*), *Busk*, 'Brit. Mus. Cat.'; Hemischara (*pars*), *Busk.*

Zoarium unilaminar, erect or crustaceous, and loosely or wholly unattached, or adnate with the zoœcia, incomplete behind.

(a). *Unilaminar, erect or crustaceous, free or loosely attached* (*hemischaran*), 'Chal. Rep.' p. 142.

1. Lepralia celleporoides, *Busk*, 'Chal. Rep.' pl. xvii. fig. 4.
2. ,, japonica, *Busk*, 'Chal. Rep.' pl. xvii. fig. 5.

3. Lepralia tuberosa, *Busk*, 'Chal. Rep.' pl. xvii. fig. 7.
4. „ dorsiporosa, *Busk*, 'Chal. Rep.' pl. xviii. fig. 4.

(b). *Adnate (lepralian)*.

5. „ fuegensis, *Busk*, 'Chal. Rep.' pl. xxii. fig. 9.
6. „ margaritifera, *Quoy & Gaymard*
   = Flustra *id.*, *Quoy & Gaymard*
   = Lepralia *id.*, *Busk*, 'Brit. Mus. Cat.' and 'Chal. Rep.' p. 145.
7. „ incisa, *Busk*, 'Chal. Rep.' p. 145, woodcut, fig. 42.
8. „ lonchæa, *Busk*, 'Chal. Rep.' p. 146, woodcut, fig. 43.
9. „ marsupium, *Macgillivray*, 'Chal. Rep.' p. 147, woodcut
   = Porella *id.*, *Hincks*
   = (?) Porella minuta, *Norman*
   = Schizoporella marsupium, *S. O. Ridley*.

The above are the whole of the species of *Lepralia* given by Mr. Busk in the 'Report.' Mr. Hincks, however, in his 'British Marine Polyzoa,' and also in the 'Contributions to a General History of the Marine Polyzoa,' adds to the list of species considerably, and the following is a full compilation from the various sources up to date :—

§. *With a simple primary orifice only.*

10. Lepralia Pallasiana, *Moll.*, 'Brit. Mar. Pol.' p. 297, pl. xxxiii. figs. 1–3; pl. xxiv. fig. 4.
11. „ canthariformis, *Busk*, *op. cit.* pl. xxxiii. fig. 4; *Busk*, 'Quart. Jour. Mic. Soc.' 1860.
   Loc.: Shetland, deep water.
12. „ foliacea, *Ell. & Sol.*, *Hincks*, p. 300, pl. xlvii. figs. 1–4.
   Var. α, fascialis, *Hincks*.
   Var. β, bidentata, *Milne-Edw.*, pl. xlvii. fig. 4.
   'For the occurrence on our coast of the remarkable variety *fascialis*, which is common in the Mediterranean, we have only the authority of Pallas, who says that he had seen a specimen from the Isle of Wight.'
   Two varieties of *L. foliacea*, Joliet has observed at Roscoff—one red and the other white. The Minch, Hebrides, is the most northern locality recorded.
   Var. α, South Devon.
13. „ pertusa, *Esper.*, *Hincks*, p. 305, pl. xliii. figs. 4, 5.
14. „ adpressa, *Busk*, *op. cit.* p. 307, pl. xxxiii. figs. 5–7.
15. „ Hippopus, *Smitt*, *op. cit.* pl. xxxiii. figs. 8, 9). *Loc.*: Northumberland coast. The only British locality.
16. „ edax, *Busk*, *op. cit.* p. 311, pl. xxiv. figs. 7, 7*a*.
17. „ polita, *Norman*, *op. cit.* p. 315, pl. xxxii. fig. 5. *Loc.*: Shetland; The Minch.

(The whole of the British *Lepralia* given by Mr. Hincks.)

18. „ Kirchenpaueri, *Heller*.
   Var. α, teres, *Hincks*, 'Annals,' July 1880, pl. ix. figs. 7, 7*a*. *Loc.*: Madeira.
19. „ cleidostoma, *Smitt*, Australian *var.* *Var.* orbicularis, *Hincks*, 'Annals,' Aug. 1881, p. 122.
20. „ Poissonii, *Aud.* (? = Escharella setigera, *Smitt*). *Loc.*: Common. Bass's Straits; Florida. 'Ann. Mag. Nat. Hist.' August 1881, p. 122.

21. Lepralia nitescens, *Hincks*, 'Ann. Mag. Nat. Hist.' June 1883, pl. xviii. fig. 6.
22. „ bilabiata, *Hincks*, *op. cit.* Jan. 1884, pl. iii. fig. 1.
23. „ claviculata, *Hincks*, *ibid.*, pl. iii. fig. 3.
„ cleidostome (19) *Smitt*, *ibid.* March 1884. *Loc.*: The species and variety. Queen Charlotte Islands.
24. „ robusta, *Hincks*, 'Annals,' May 1884, pl. xiii. fig. 4. *Loc.*: India; coast of Burmah.
25. „ foraminigera, *Hincks*, 'Annals,' March 1883, p. 200, pl. vii. fig. 1.
26. „ rectilineata, *Hincks*, *ibid.* p. 201, pl. vii. fig. 5. *Loc.*: New Zealand (*Miss E. C. Jelly*).
27. „ bifrons, *Hincks*, 'Annals,' May 1884, p. 281, pl. viii. fig. 3. *Loc.*: Port Phillip Heads, Victoria.
28. „ cincta, *Hincks*, 'Annals,' May 1885, pl. viii. fig. 6.
29. „ subimmersa, *Macgil.*, *ibid.* pl. viii. fig. 1. *Loc.*: New Zealand (28); Port Phillip Heads, Victoria (29).
30. „ striatula, *Hincks*, 'Annals,' August 1882, pl. viii. fig. 2. *Loc.*: Zanzibar.

The following are also referable to the genus :—

31. Lepralia inornata, *Smitt*.
32. „ turrita, *Smitt*.
33. „ rostrigera, *Smitt* = Escharella *id.*, 'Florid. Bryozoa.'
34. „ Audouinii, *Smitt* = „ „ „
35. „ setigera, *Smitt* = „ „ „
36. „ depressa, *Busk*.
37. „ gigas, *Hincks*, 'Annals,' March 1885, pl. ix. fig. 8. *Loc.*: Trincomalee.
38. „ vestita, *Hincks*, *ibid.* pl. ix. fig. 9. *Loc.*: Tahiti, Fiji Islands.
39. „ radiatula, *Hincks*.
40. „ punctata, *Hincks*.

In a rather full list of Macgillivray, Australian species[1] kindly compiled for me by Miss E. C. Jelly, other *Lepralia* are catalogued. These I give, as well as other forms, on Macgillivray's authority. Some of his species have been adopted by Mr. Hincks and Mr. Busk: these do not appear in the list, but as they are fully referred to in the body of the present Report, the absent names will not cause any surprise.

Genus 66. Chorizopora, *Hincks*

= Mollia (sp.), *Smitt*; Hippothoa (*pars*), *Smitt*.
Schizoporella (*pars*), *Hincks*.

'Zoœcia often distinct, connected by hollow calcareous processes. Mouth semicircular or sub-orbicular, with a straight or sinuated lower border. Oœcial orifice crescentic. Wall of zoœcia usually transversely wrinkled.'—*Chal. Rep.* p. 148.

1. Chorizopora Brongniartii, *Aud.* (sp.), 'Chal. Rep.' p. 148, for synonyms.

[1] This list will be found among the Australian and Pacific lists on pp. 163–166.

2. Chorizopora hyalina.
Var. Bougainvillei, *Busk*
=Escharina Bougainville, *D'Orb.*
=Lepralia hyalina, *var.* Bougainvilla, *Busk*, 'Chal. Rep.' pl. xxii. fig. 4; 'Kerguelen Polyzoa,' *Busk.*
3. „ Honolulensis, *Busk*, 'Chal. Rep.' pl. xxii. fig. 12.

Only one species (No. 1, the type of the genus) is given by Mr. Hincks in his 'Brit. Mar. Polyzoa.'

Genus 67. Porella, *Gray*

=Porella, *Hincks*, *Smitt* (*pars*), *Gray*, 'Brit. Mus. Radiata.'
=Eschara (*pars*), *Sars.*, *Busk*, *Alder*, *Smitt*
=Hemischara and Lepralia, *Norman* & *Busk.*

'Zoarium erect, ramose, cylindrical, or sub-compressed, or crustaceous and adnate. A median oral avicularium within the primary mouth, with a semi-orbicular or sub-triangular mandible.'—*Chal. Rep.* p. 149.

1. Porella lævis, *Fleming* (*Hincks*, 'Brit. Mar. Polyzoa,' p. 334).
Var. subcompressa, *Hincks*, 'Chal. Rep.' pl. xx. fig. 3.

The only form described by Mr. Busk, who says 'that the difference between this and the usual cylindrical form of the northern *Porella lævis* is sufficient to mark it as a distinct variety.' *Loc.*: Cape de Verde.

Several British species of *Porella* are described by Mr. Hincks, and the list is added to in his descriptions of foreign *Cheilostomata*. 'Throughout this very natural group,' says Mr. Hincks ('Brit. Mar. Polyzoa,' p. 321), 'there is a striking uniformity, not only in the characters of the adult cell, but also in the course of its development; and the study of it has done more than most things to convince me that in this section of the Polyzoa we cannot safely regard the mere erect and branching habit as a generic criterion.' In further remarks Mr. Hincks points out many peculiarities of structure in the several species to which he directs attention.

α. Zoarium incrusting.

2. Porella concinna, *Busk*, 'Brit. Mar. Polyzoa,' p. 323, pl. xlvi.
Var. α, Belli, *Dawson* (*id.*, pl. xlvi. fig. 6).
„ *β*, gracilis, *Hincks* (*id.*, fig. 9).
Loc.: *var. α*, Shetland and Gulf of St. Lawrence.
3. „ minuta, *Norman*, *op. cit.* p. 326, pl. xxix. figs. 1, 2; pl. xxxvi. figs. 6, 8
= (?) Lepralia chilopora, *Manzoni.*

β. Zoarium incrusting, or erect and unilamellate.

4. Porella struma, *Norman*, *op. cit.* p. 329, pl. xxxix. figs. 3, 5
=Hemeschara *id.*, *Norman.*
Loc.: Shetland (rare); Bergen.

γ. Zoarium erect; branches compressed.

5. Porella compressa, *Sowerby*, *op. cit.* p. 330, pl. xlv. figs. 4, 7, and woodcut, p. 322.

δ. *Zoarium erect; branches cylindrical.*

6. Porella lævis, *Fleming*, *op. cit.* p. 334, pl. xlvii. figs. 10, 11.
Range: from Shetland to Arctic Sea.

The above are all British species.

7. Porella nitidissima, *Hincks*, 'Ann. Mag. Nat. Hist.' July 1880, pl. x. fig. 2. *Loc.*: Madeira (*Hincks*).
8. „ rostrata, *Hincks*, *op. cit.* Nov. 1880, p. 382, pl. xvii. fig. 5; and 'Annals,' Feb. 1882, p. 89, pl. v. fig. 2. *Loc.*: Australia (*Miss Jelly* and *Miss Gatty*).
9. „ marsupium, *Macgil.*, *op. cit.* Aug. 1881, p. 123, pl. i. fig. 6. *Loc.*: Bass's Straits.
10. „ Form, porifera, *Hincks* ('Annals,' Jan. 1884, pl. iv. fig. 4). *Loc.*: Victoria, *Macgil.*; Bass's Straits; Queen Charlotte Islands.
11. „ major, *Hincks* ('Annals,' Jan. 1884, pl. iv. fig. 5).
12(?). „ argentea, *Hincks* ('Annals,' March 1884, pl. ix. fig. 1). *Loc.*: Queen Charlotte Islands.
13. „ malleolus, *Hincks* ('Annals,' May 1884, p. 361). *Loc.*: Coast of Burmah.

Genus 68. Escharoides, *Smitt.*

'Secondary orifice sinuated below, with an avicularium on one or both sides of the notch.'—*Chal. Rep.* p. 149.

1. Escharoides occlusa, *Busk*, 'Chal. Rep.' pl. xxi. fig. 8.
2. „ verruculata, *Smitt* (sp.), 'Chal. Rep.' p. 150 = Cellepora *id.*, *Smitt*, 'Florid. Bryozoa.'

Only two species are described by Mr. Hincks in his 'British Marine Polyzoa,' 1880:—

4. Escharoides rosacea, *Busk*, *op. cit.* p. 336, pl. xlvii. figs. 5–9. *Loc.*: Orkney; Shetland; Norway; Spitzbergen.
5. „ quincuncialis, *Norman*, *op. cit.* p. 339, pl. xv. fig. 7. *Loc.*: Deep water, in The Minch.

Genus 69. Smittia, *Hincks*

= Escharella, *Smitt* (not Escharella, *Gray* or *D'Orb.*), Smittia, *Hincks*, 'Ann. Mag. Nat. Hist.' 1879.

'Zoarium erect, bi- or uni-laminar, or crustaceous, free or adnate. Primary orifice entire, with an internal median denticle. Secondary orifice canaliculate, usually inclosing a median avicularium.'—*Chal. Rep.*, p. 150.

(a). *Bilaminar (escharan).*

1. Smittia tenuis, *Busk*, 'Chal. Rep.' pl. xx. fig. 1.

(b). *Unilaminar, erect or crustaceous (hemischaran).*

2. Smittia Smittiana, *Busk*, 'Chal. Rep.' pl. xvii. fig. 2.
3. „ marsupialis, *Busk*, 'Chal. Rep.' pl. xviii. fig. 1.
4. „ transversa, *Busk*, 'Chal. Rep.' pl. xviii. fig. 7.
5. „ marionensis, *Busk*, 'Chal. Rep.' pl. xviii. fig. 6 = Lepralia *id.*, *Busk*, 'Brit. Mus. Cat.'
6. „ Jacobensis, *Busk*, 'Chal. Rep.' pl. xix. fig. 7.

(c). *Adnate (lepralian).*

7. Smittia oratavensis, *Busk*, 'Chal. Rep.' pl. xxii. fig. 1.
(?) S. marmorea, *Hincks*, 'Brit. Mar. Polyzoa,' p. 350.
8. ,, stigmatophora, *Busk*, 'Chal. Rep.' pl. xxii. fig. 6.
9. ,, graciosa, *Busk*, 'Chal. Rep.' pl. xxii. fig. 13.
(?) Porella concinna, *var.* β, gracilis, *Hincks*.

Several species are described in the 'British Marine Polyzoa' and in the 'Contributions' of Mr. Hincks.

10. Smittia Landsborovii, *Johnston*, 'Brit. Mar. Polyzoa,' p. 341, pl. xlviii. figs. 6–9. Widely distributed.
Var. α, crystallina, *Norman* (pl. xxxvi. fig. 2). *Loc.*: The Minch, Shetland; Antrim.
Var. β, porifera, *Smitt* (p. 344). *Loc.*: South Devon; Arctic Seas.
Var. γ, purpurea, *Hincks*, 'Annals,' Aug. 1881. *Loc.*: Bass's Straits; Victoria, Australia.
11. ,, reticulata, *Macgil.* 'Brit. Mar. Pol.' p. 346, pl. xlviii. figs. 1–5. *Loc.*: Various British localities; Bass's Straits: Victoria, Australia.
12. ,, affinis, *Hincks*, *op. cit.* p. 348, pl. xlix. figs. 10, 11. *Loc.*: Start Bay, South Devon.
13. ,, cheilostomata, *Manzoni*, *op. cit.* p. 349, pl. xlii. figs. 7, 8 =Lepralia *id.*, *Manzoni*. *Loc.*: Guernsey; South Devon; Hastings.
14. ,, marmorea, *Hincks*, *op. cit.* p. 350, pl. xxxvi. figs. 3–5. *Loc.*: Cornwall; Guernsey.
15. ,, Bella, *Busk*, *op. cit.* pl. xlii. figs. 9, 10. *Loc.*: Shetland = Lepralia *id.*
16. ,, trispinosa, *Johnston*, *op. cit.* p. 353, pl. xlix. figs. 1–8. *Loc.*: Several British, and widely distributed geographically.
Mr. Hincks describes several varieties in 'Annals,' May 1884, pp. 361, 362, pl. xiii. figs. 7, 7*a*.
Var. α, Jeffreysi, *Norman*. *Loc.*: Dogger Bank (*T. Hincks*).
17. ,, galeata, *Busk*. *Loc.*: Madeira.
18. ,, nitida, *Verrill*. ('Annals,' Feb. 1881, p. 159, pl. ix. figs. 5, 5*a*). *Loc.*: North America (*Verrill*); Africa (*Miss Jelly*).
19. ,, plicata, *Smitt* = Cellepora plicata, *Smitt*.
20. ,, spathulifera, *Hincks*, 'Annals,' Jan. 1884, pl. iv. fig. 3. *Loc.*: Houston Stewart Channel ('Polyzoa of Queen Charlotte Islands').
Var. munita, *Hincks*.
,, spathulata, *Smitt*.
form bimucronata, *Hincks*.

Genus 70. Mucronella, *Hincks*.

'Brit. Mar. Polyzoa,' p. 360.

'Zoarium erect and bi- or uni-laminar, or crustaceous and unattached, or adnate. Orifice mucronate in front.'—*Chal. Rep.*, p. 155.

a. Bilaminar (escharan).

1. Mucronella contorta, *Busk*, 'Chal. Rep.' pl. xx. fig. 9
   = Eschara *id.*, *Busk*, 'Brit. Mus. Cat.' p. 89, pl. cviii. figs. 1-3.
2. " pyriformis, *Busk*, 'Chal. Rep.' pl. xx. fig. 5.

β. Unilaminar, erect or crustaceous, unattached (hemischaran).

3. Mucronella quadrata, *Busk*, 'Chal. Rep.' pl. xviii. fig. 5; and pl. xvii. fig. 8.
4. " delicatula, *Busk*, 'Chal. Rep.' pl. xviii. fig. 2.
5. " rostrigera, *Busk*, 'Chal. Rep.' pl. xix. fig. 2.
6. " bisinuata, *Smitt*, 'Chal. Rep.' pl xix. fig. 5
   = Escharella *id.*, 'Florid. Bryozoa,' p. 59.
7. " castanea, *Busk*, 'Chal. Rep.' pl. xix. fig. 6.
8. " magnifica, *Busk*, 'Chal. Rep.' pl. xviii. fig. 3.

γ. Adnate (lepralian).

9. Mucronella canalifera, *Busk*, 'Chal. Rep.' pl. xxii. fig. 2.
   ? Phylactella (sp.)
   = Lepralia Mangueville, *Busk*, 'Quart. Jour. Micr. Soc.' vol. xiii. p. 284. This form differs from *Lepralia* (*Phylactella*) *labrosa*, and also from *L.* (*Phylactella*) *collaris*—in the one case in the absence of an internal denticle, and in the other in the presence of oral spines and the absence of punctu-ration on the oœcium.
10. " tricuspis, *Hincks*, 'Chal. Rep.' pl. xxii. fig. 3; and *Hincks*, 'Ann. Mag. Nat. Hist.' 1881.
11. " simplicissima, *Busk*, 'Chal. Rep.' pl. xxii. fig. 5. Probably an adnate variety of No. 2.
12. " ventricosa, *Busk* (Lepralia *id.*, 1861, *var.* multispinata, *Busk*)
   = (?) Mucronella Peachii, *var.* octodentata, *Hincks*, 'Brit. Mar. Polyzoa.'

I think it best to give, in addition to the above, the *Mucronellæ* as worked out by Mr. Hincks both in his 'British Marine Polyzoa' and also in his 'Contributions.'

The genus *Mucronella* 'is equivalent in part to the *Discopora* of Smitt, but not of Fleming, who originated the name for a species belonging to a totally different section of the Polyzoa (the *Cyclostomata*), with which it is still connected in the slightly modified form *Discoporella*.'—*Hincks*, 'Brit. Mar. Polyzoa,' p. 360.

a. Without avicularia.

13. Mucronella Peachii, *Johnst.* ('Brit. Mar. Polyzoa,' p. 360, pl. l. figs. 1–5; pl. li. figs. 1, 2).
   Var. a, labiosa, *Busk*, pl. li. fig. 1. *Loc.*: Belfast Bay; Guernsey.
   Var. β, octodentata, *Norman*, pl. li. fig. 2. *Loc.*: Shetland.

14. Mucronella ventricosa, *Hassall*, *op. cit.* pl. l. figs. 6–8
= Lepralia arrecta, *Reuss*, Miocene.
Var. connectans, *Ridley*, 'Polyzoa of Franz Josef's Land.'
15. „ variolosa, *Johnst.* 'Brit. Mar. Polyzoa,' p. 366, pl. li. figs. 3–7.
16. „ laqueata, *Norman*, *op. cit.* pl. li. fig. 8. *Loc.*: Shetland; The Minch; Antrim; Bergen; Arctic Seas.
17. „ abyssicola, *Norman*, *op. cit.* pl. xxxviii. figs. 1, 2. *Loc.*: Shetland; Gulf of St. Lawrence.
18. „ macrostoma, *Norman*, *op. cit.* pl. xxxviii. figs. 3, 4. *Loc.*: Shetland Seas; On the Falmouth-Lisbon Cable, between N. lat. 47° 58′ and 47° 35′, and in W. long. 7° 6′.

β. With a lateral avicularia.

19. Mucronella coccinea, *Abildgard*, *op. cit.* pl. xxxiv. figs. 1–6.
Var. a, mamillata, *Hincks*. *Loc.*: Coast of Antrim.
20. „ pavonella, *Alder*, *op. cit.* pl. xxxix. figs. 8–10.
These are the whole of the British species; some of them, such as Nos. 13, 14, 15, and 19, have a very wide range.
21. „ simplex, *Hincks*, Polyzoa for Barrent's Sea, 'Annals,' Oct. 1880, p. 280, pl. xv. fig. 7.
22. „ (?) tubulosa, *Hincks*, *op. cit.* Nov. 1880, p. 383, pl. xvii. fig. 7. *Loc.*: Australia.
23. „ porosa, *Hincks*, *op. cit.* Aug. 1881, p. 124, pl. i. fig. 5. *Loc.*: Off Curtis Island (Polyzoa Bass's Straits); Singapore or the Philippines (*Miss Jelly*).
24. „ teres, *Hincks*, *op. cit.* pl. ii. fig. 5. Allied to the Brit., No. 14, *ante*. *Loc.*: Off Curtis Island.
25. „ spinosissima, *Hincks*, *op. cit.* pl. iii. fig. 3. *Loc.*: Off Curtis Island.
Var. major, *Hincks*, 'Polyzoa of Queen Charlotte Islands,' *op. cit.* Jan. 1884, pl. iii. fig. 3.
26. „ tricuspis, *Hincks*, *op. cit.* Aug. 1881, p. 125, pl. iii. fig. 1. *Loc.*: Off Curtis Island.
27. „ vultur, *Hincks*, *op. cit.* Aug. 1882, pl. viii. fig. 2. *Loc.*: Australia.
28. „ diaphana, *Macgil.*
Var. armata, *Hincks*, *op. cit.* pl. viii. fig. 3. *Loc.*: New Zealand.
29. „ præstans, *Hincks*, *op. cit.* pl. viii. fig. 1. *Loc.*: Australia.
30. „ rotundata, *Hincks*, *op. cit.* pl. viii. fig. 5. *Loc.*: Singapore or Philippines (*Miss Jelly*).
31. „ prælucida, *Hincks*, *op. cit.* Jan. 1884, pl. iv. fig. 1.
32. „ prælonga, *Hincks*, *op. cit.* pl. iv. fig. 2. *Loc.*: Houston Stewart Channel.
33. „ bicuspis, *Hincks* (?)
34. „ mucronata, *Hincks* (?)

Mr. Hincks gives very full details of the special features of the

Mucronellæ described in his various papers, especially so in describing the species in Captain Warren's collection from Bass's Straits, and Dr. Dawson's from the neighbourhood of Queen Charlotte Islands.

Genus 71. Aspidostoma, *Hincks.*

'Zoarium dimorphous, uni- or bi-laminar; erect, solid, rising from a contracted calcareous base, or expanded and foliaceous. Zoœcia with the front depressed in the centre and the sides tumid. Mouth quite at the summit of the depressed area, concealed under the tumid border, on which above the mouth is a penthouse-like, usually bifid, projection. The mouth arched above, straight below, and protected in front by a broad shield-like plate or mucro which is continued downwards for some distance within the zoœcium.'—*Chal. Rep.* p. 161.

1. Aspidostoma giganteum, *Blainv.*, 'Chal. Rep.' pl. xxxiii. fig. 3
   =Eschara gigantea, *Blainv.*, 'Brit. Mus. Cat.' p. 91
   =Aspidostoma crassum, *Hincks*, 'Ann. Mag. Nat. Hist.' Feb. 1881.
2. „ crassum, *Hincks*, 'Annals,' Feb. 1881, p. 160, pl. x. figs. 6, 6*a*. *Loc.*: Patagonia and the Falkland Islands.

§ 2. *Primary mouth notched or sinuated below.*

Genus 72. Schizoporella, *Hincks*, 'Brit. Mar. Polyzoa.'

'Zoarium erect and bi- or uni-laminar, or crustaceous and unattached, or adnate. Lower lip with a median notch. Operculum pedunculate or contracted below.'—*Chal. Rep.* p. 162.

α. *Bilaminar* (*escharan*).

1. Schizoporella furcata, *Blainv.*, 'Chal. Rep.' pl. xxi. fig. 5.

β. *Unilaminar* (*hemischaran*).

2. Schizoporella nivea, *Busk*, 'Chal. Rep.' pl. xvii. fig. 1.
3. „ longispinata, *Busk*, 'Chal. Rep.' pl. xvii. fig. 2.
4. „ auriculata (?), *Hassall.*
   Var. alba, *Busk*, 'Chal. Rep.' pl. xix. fig. 1.
5. „ Jacksoniensis, *Busk*, 'Chal. Rep.' pl. xix. fig. 3.
6. „ tenuis, *Busk*, 'Chal. Rep.' pl. xx. fig. 10.

γ. *Adnate* (lepralian).

7. Schizoporella elegans, *D'Orb.* = (?) Escharina *id.*, 'Voy. en Amér. Mérid.'
   (?) Lepralia squamoidea, *Reuss & Manzoni*, 'Castrocaro.'
8. „ marsupifera, *Busk*, 'Chal. Rep.' pl. xxii. fig. 14.
9. „ Cecillii, *Aud.* (sp.), 'Chal. Rep.' p. 166; and *Hincks*, 'Brit. Mar. Polyzoa,' p. 262.
10. „ circinata, *Macgil.* = Lepralia, *id.*, *Macgil.*, 'Nat. Hist. Vict.' and 'Chal. Rep.' p. 166, woodcut.
11. „ triangula, *Hincks*, 'Annals,' 1881; 'Chal. Rep.' p. 167.

In addition to the above list of forms described by Mr. Busk from the 'Challenger' collection, no fewer than fifty-two species and varieties have

been described by Mr. Hincks, in his 'British Marine Polyzoa' and in his Contributions in the 'Annals and Mag. Nat. History,' under the family name Myriozoidæ.

a. *Avicularia with a pointed mandible, generally lateral.*

12. Schizoporella unicornis, *Johnst.*, 'Brit. Mar. Polyzoa,' p. 238, pl. xxxv. figs. 1–5.
Form ansata, *Johnst.* *Loc.*: form *ansata*: Greenland; Bergen. The form *unicornis* widely distributed.

13. „ spinifera, *Johnst.*, *op. cit.* pl. xxxv. figs. 6–8. *Loc.*: Not so widely distributed as No. 12.

14. „ Alderi, *Busk*, *op. cit.* pl. xxxvi. figs. 9, 10. *Loc.*: Shetland; Hammerfest; Bergen; Southern Norway.

15. „ vulgaris, *Moll.*, *op. cit.* pl. xxxvii. fig. 7; pl. xv. figs. 5, 6. *Loc.*: Polperro, S.W. of; Antrim; Hastings; Birterbuy Bay; Naples; Madeira.

16.[1] „ simplex, *Johnst.*, *op. cit.* pl. xxxv. figs. 9, 10. *Loc.*: Sana Island; Antrim; Belfast Bay; South Devon (rare); Guernsey; Hastings; Northern Hebrides; Unst, Shetland; Peterhead and Wick.

17. „ linearis, *Hassall*, *op. cit.* pl. xxxviii. figs. 5–10; pl. xxiv. fig. 1.
Var. α, hastata, *Hincks*, pl. xxxiii. fig. 10.
„ β, mamillata, *Hincks.*
„ γ, nitida, *Hincks.*
„ δ, crucifera, *Norman.*
Loc.: Several are given by Mr. Hincks, p. 251.

18. „ sanguinea, *Norman*, *op. cit.* pl. xxxix. figs. 6, 7 = Hemeschara, *id.*, *Norman.*
Loc.: Guernsey; Naples; Cornwall; Florida.

19. „ cristata, *Hincks*, *op. cit.* pl. xl. fig. 6, 6*a*. *Loc.*: Hastings (*Miss Jelly*).

b. *With a rounded or spatulate avicularia, lateral or median.*

20. Schizoporella biaperta, *Michelin*, *op. cit.* pl. xl. figs. 7–9.
Form eschariformis, *Waters*
≐ (?) Hippothoa divergens, *Smitt.*
Loc.: *var.* divergens, Guernsey; Hastings; Algiers; Florida. *Var.* biaperta, Spitzbergen; Kara Sea; Florida. *Var.* eschariformis, Bruccoli (fossil).

21. „ armata, *Hincks*, *op. cit.* pl. xli. figs. 7, 8. *Loc.*: Polperro, S.W.; Algiers.

(4.) „ auriculata, *Hassall* (see Busk's list, No. 4) (*Hincks*, *op. cit.* pl. xxix. fig. 3–9).
Var. α, ochracea, *Hincks* = Lepralia auriculata, *var.* Leontiniensis, *Waters.*
Var. β, cuspidata, *Hincks.*
Loc.: Very widely distributed and common.

22. „ umbonata, *Busk*, *op. cit.* pl. xxiv. fig. 2. *Loc.*: Shetland (Barlee).

[1] See No. 53, p. 98.

23. Schizoporella discoidea, *Busk, op. cit.* pl. xxx. figs. 8, 9
= Alysidota conferta, *Busk*, 'Rep. Brit. Assoc.'
Loc.: Shetland; Antrim; Hastings; Guernsey; Madeira; Algiers; Birterbuy Bay.

c. *Usually without avicularia.*

24. Schizoporella sinuosa, *Busk, op. cit.* pl. xlii. figs. 1–6.
Var. α, armata, pl. xlii. fig. 2.
Loc.: Shetland; W. coast Scotland; Spitzbergen, and other Arctic localities; Gulf of St. Lawrence.

(9.) „ Cecilii, *Aud., op. cit.* pl. xliii. fig. 6. *Loc.*: Jersey; Guernsey; Algiers; (?) Adriatic; Naples; Cornwall; Australia (*Miss Jelly*).

25. „ cruenta, *Norman, op. cit.* pl. xxx. fig. 5. *Loc.*: Shetland (rare); Peterhead (rare); Orkney; Channel Islands; Nova Zembla; Greenland.

26. „ hyalina, *Linn., op. cit.* pl. xviii. figs. 8–10.
Var. α, cornuta, pl. xlv. fig. 2 (Australia; California; New Zealand, &c.)
„ *β*, incrassata.
„ *γ*, tuberculata.
Loc.: Widely distributed. Coasts of Great Britain and Ireland; and, as regards geographical range, cosmopolitan.

d. *Avicularia on a distinct area above the cell.*

27. Schizoporella venusta, *Norman, op. cit.* pl. xxx. fig. 6
= Gemellipora glabra, forma, striatula, *Smitt.*
Loc.: Off Guernsey; Florida.

The above are the whole of the British species given by Mr. Hincks.

(11.) Schizoporella triangula, *Hincks*, Polyzoa Bass's Straits, Liverpool Address, *Hincks*, April 1881.

28. „ tumida, *Hincks*, Polyzoa Bass's Straits, Ibid.

29. „ acuminata, *Hincks*, Polyzoa Bass's Straits, Ibid.

30. „ insignis, *Hincks*, 'Annals,' Aug. 1881, p. 134, pl. v. fig. 10. 'As bearing on the morphological relations' (of the special pore of the Microporellidæ) 'of this portion of structure, an observation by Mr. Ridley ("Annals," June 1881, p. 448, &c.) is interesting. He has noticed a Myriozoidan stage in the development of a Porinidan cell, in which the pore had not yet become isolated, but was connected by a gap with the orifice.'—*Hincks*, 'Annals,' Aug. 1881, p. 135. *Loc.*: Africa.

31. „ incrassata, *Hincks* ('Annals,' Feb. 1882, p. 124, pl. v. figs. 1, 1*a*). *Loc.*: Africa, on coral (*Miss Jelly*).

32. „ levata, *Hincks* (*ibid.*, pl. v. fig. 4). *Loc.*: Australia, on weed (*Miss Jelly*).

33. „ aperta, *Hincks* (*ibid.*, pl. v. fig. 3). *Loc.*: Singapore (*Miss Jelly*).

34. Schizoporella crassilabris, *Hincks* ('Annals,' June 1883, pl. xviii. fig. 1).
35. ,, crassirostris, *Hincks* (*ibid.* pl. xviii. fig. 3).
36. ,, longirostrata, *Hincks* (*ibid.* pl. xvii. fig. 4).
37. ,, insculpta, *Hincks* (*ibid.* pl. xvii. fig. 5, 5*a*).
38. ,, tumulosa, *Hincks* (*ibid.* pl. xviii. fig. 2).
39. ,, pristina, *Hincks* (*ibid.* pl. xvii. fig. 6).
40. ,, maculosa, *Hincks* (*ibid.* No figure).
41. ,, torquata, *D'Orb.* ('Annals,' March 1884, pl. ix. fig. 2).
= S. Dawsoni, *Hincks*, 'Annals,' June 1883.
Loc.: From 34 to 41, 'Polyzoa of Queen Charlotte Islands.'
42. ,, cinctipora, *Hincks* ('Annals,' March 1883, p. 200, pl. vii. fig. 3). *Loc.*: New Zealand (*Miss Jelly*).
43. ,, biserialis, *Hks.* ('Annals,' March 1885, pl. vii. fig. 3) = S. arachnoides, *Macgil.* *Loc.*: New Zealand.
44. ,, cribrillifera, *Hincks* (*ibid.*, pl. viii. fig. 5). *Loc*: Cook's Straits, New Zealand.
45. ,, scintillans, *Hincks* (*ibid.*, pl. ix. fig. 7). *Loc.*: New Zealand.
46. ,, lucida, *Hincks* (*ibid.*, pl. ix. fig. 5). *Loc.*: Australia, on weed.
(10.) ,, circinata, *Macgil.* (*ibid.*, pl. vii. fig. 1). *Loc.*: Napier, New Zealand; Victoria, *Macgil.*
47. ,, argentia, *Hincks* (*ibid.*, pl. ix. fig. 6, and 'Annals,' Feb. 1881, p. 158, pl. ix. fig. 66*a*). *Loc.*: Africa, on coral.
(17.) ,, linearis, *Hassall.*
Form, quincuncialis, *Hincks*, 'Annals,' Feb. 1881, p. 158, pl. ix. fig. 3. *Loc.*: Ceylon (*Miss Jelly*).
48. ,, fissurella, *Hincks.*
49. ,, latisinuata, *Hincks.*
50. ,, subsinuata, *Hincks.* } 'Annals,' 1884, vol. xiv. pp. 280,
51. ,, biturrita, *Hincks.* } 281. Port Phillip Heads.
52. ,, marsupium, *Ridley*, 1881 = S. Ridleyi, *Macg.*
53. ,, Johnstoni, *Quelch* = S. simplex, *Johnston* (non *D'Orb.*), 'Annals,' xiii. 1884, pp. 51 and 215–217.

Genus 73. Gephyrophora, *Busk.*

'Zoarium dimorphous, either erect and irregularly branched, and cylindrical, with the zoœcia disposed round an imaginary axis, or decurrent, loosely incrusting, and unilaminar. Zoœcia completely immersed, flat in front, parted by septal ridges. Surface beneath the epitheca finely reticulate. Primary orifice arcuate, with the lower border slightly sinuated, afterwards transversely oblong. A prominent avicularian process on each side of the orifice, the two eventually inarching and forming a bridge in front of it.'—*Chal. Rep.* p. 167.

Gephyrophora polymorpha, *Busk*, 'Chal. Rep.' pl. xxxi.

Genus 74. Myriozoum, *Donati.*

'Zoarium erect, branched, continuous; branches cylindrical, obtuse, or oviform. Surface punctured or reticulate. Avicularia, when pre-

sent, immersed, and usually placed near the orifice, either above, below, or on one or both sides. Orifice notched or sinuate, or caniculate below.'—*Chal. Rep.* p. 168.

§ 1. *Myriozoa typica.*

1. Myrizoum truncatum, *Donati.*
2. „ subgracile, *D'Orbigny.*
3. „ coarctatum, *Sars.*

Referred to and placed as above in the 'Challenger Report' (p. 169), but not otherwise described.

§ 2. *Myriozoa dubia.*

1. Myriozoum honolulense, *Busk*, 'Chal. Rep.' pl. xxv. fig. 2
2. „ immersum, *Busk*, 'Chal. Rep.' pl. xxv fig. 4.
3. „ simplex, *Busk*, 'Chal. Rep.' pl. xxv. fig. 1.
4. „ Marionense, *Busk*, 'Chal. Rep.' pl. xxiii. fig. 6.

Genus 75. Haswellia, *Busk*

= Myriozoum (sp.), *Haswell.*

Zoarium composed of short cylindrical branches, spreading in all directions dichotomously at very open angles. Zoœcia disposed verticellately, and more or less irregularly quincuncial, with a produced tubular or sub-tubular and bifid, or simply thickened peristome, supporting on each side a small avicularium with a pointed subtriangular mandible. Primary mouth clithridiate, with an operculum of corresponding form.

1. Haswellia australiensis, *Haswell*, 'Chal. Rep.' pl. xxiv. fig. 9
   = Myriozoum australiense, 'Proc. Lin. Soc. N. S. Wales,' 1880.
2. „ auriculata, *Busk*, 'Chal. Rep.' pl xxiv. fig. 10.

Genus 76. Tessarodoma, *Norman*

= Pastulopora (pars), *Sars*; Quadricellaria, *Sars*; *Alder*
= Anarthropora, *Smitt*; Tessarodoma, *Norman.*
Porina (part), *Hincks.*

Tessaradoma boreale, *Busk*, 'Chal. Rep.' p. xxiv. fig. 8
= Pastulopora gracilis, *Sars*
= Quadricellaria gracilis, *Sars*
= Onchopora borealis, *Busk*
= Anarthropora borealis, *Smitt*
= Tessarodoma gracile, *Norman*
= Tessarodoma boreale, *Smitt*
= Porina borealis, *Hincks.*

Genus 77. Gemellipora, *Smitt.*

Gemellipora (pars), *Smitt*, 'Florid. Bryozoa.'

'Zoarium erect and ramose, or crustaceous and adnate. Mouth elongate, pyriform, with an articular notch on either side below. Operculum of corresponding pyriform shape. A median immersed avicularium, either above or below the mouth.'—*Chal. Rep.* p. 176.

α. Erect and ramose (escharan).

1. Gemellipora glabra, *Smitt*, 'Chal. Rep.' pl. xxv. fig. 3
= G. glabra (forma typica), 'Florid. Bryoz.'

β. Adnate (lepralian).

2. Gemellipora cribritheca, *Busk*, 'Chal. Rep.' pl. xxxiii. fig. 5.

The following four genera, established by Mr. Hincks for British species of Marine Polyzoa, are not accepted—or only partly accounted for—in the classification of Mr. Busk :—

Genus 78. Umbonula, *Hincks*.

'Zoœcia with a primary orifice, sub-orbicular or sub-quadrangular, lower margin slightly curved inwards, peristome not elevated, no secondary orifice; a prominent umbo (? avicularian cell) immediately below the mouth, supporting an avicularium. Zoarium (in British species) incrusting.'—*Brit. Mar. Poly.* p. 316.

Umbonula verrucosa, *Esper.* (Umbonella, text, p. 316), pl. xxxix. fig. 1, 2. *Loc.*: Several British; Roscoff; Adriatic (rare); Greenland.

Genus (78?). Phylactella, *Hincks*
= Lepralia (*Auctt*, part) = Alysidota (sp.), *Busk*.

'Zoœcia with the primary orifice more or less semicircular, the lower margin usually dentate; peristome much elevated, not produced or channelled in front. No avicularia. Zoarium (in British species) incrusting.'—*Brit. Mar. Polyzoa*, p. 356.

1. Phylactella labrosa, *Busk* (*Hincks*, pl. xliii. fig. 12). *Loc.*: Antrim; Shetland; S. Devon; Hastings; Wick; Cornwall.
2. ,, collaris, *Norman*, *op. cit.* pl. xliii. fig. 3. *Loc.*: Hebrides, Shetland; Guernsey; Hastings; Antrim.
3. ,, exima, *Hincks*, *op. cit.* pl. xlix. fig. 11. *Loc.*: Antrim; off the Deadman; Shetland.
4. ,, lucida, *Hincks*, 'Annals,' July 1880, pl. x. fig. 4. *Loc.*: Madeira.

Genus 79 (?). Palmicellaria, *Alder*.

'Zoœcia with the primary orifice orbicular, or ranging from semicircular to semi-elliptical; the peristome elevated around it, so as to form a secondary orifice, and carried out in front into a projecting palmate or mucronate process, with an avicularium on its inner aspect. Zoarium (in the British species) erect and ramose, or (?) lamellate.'—*Brit. Mar. Polz.* p. 378.

1. Palmicellaria elegans, *Alder*, *op. cit.* pl. xxx. figs. 7–9. *Loc*: Zetland Seas; Loch Fyne.
2. ,, Skenie *Ell.* and *Sol.*, *op. cit.* pl. lii. figs. 1–4.
   Var. α, bicornis, *Busk* (Crag form).
   ,, *β*, foliacea. *Loc.*: Wick.
   ,, *γ* tridens, *Busk*. Norway.
3. ,, lorea, *Alder* ('Brit. Mar. Pol.' pl. lii. figs. 5, 6). *Loc.*: Shetland.
4. ,, (?) cribraria, *Johnston*. (Provisionally placed.) *Loc.*: Berwick Bay, *Johnston*.

Family **Myriozoidæ**, *Hincks.*

Genus 53 (?). Rhynchopora, *Hincks.*

'Zoœcia with the primary orifice transversely elliptical, lower margin slightly sinuated; secondary orifice sub-orbicular, with a mucro on the lower margin and an uncinate process immediately above it within the mouth. Zoarium (in the British species) incrusting.'—*Brit. Mar. Pol.* p. 385.

1. Rhynchopora bispinosa, *Johnston, op. cit.* p. xl. figs. 1–5. *Loc.*: Berwick Bay; South Devon (abundant): Cornwall; Guernsey; Shetland; Caithness (very rare); Mazatlan; Adelaide.
2. „ longirostris, *Hincks*, 'Annals,' May 1881. Captain Warren's collection.

Genus 54 (?). Schizotheca, *Hincks.*

'Brit. Mar. Polyzoa,' p. 283.

1. Schizotheca fissa, *Busk*, 'Brit. Mar. Pol.' p. 284, pl. xli. figs. 1–3.
2. „ divisa *Norman, op. cit.* p. 385, pl. xli. figs. 4–6.
3. „ fissurella, *Hincks*, 'Annals,' 1882, 'Polyzoa of Queen Charlotte Islands.'

———

Genus 54*. Mastigophora, *Hincks.*

(See Genus 62 of Report, and 'Brit. Mar. Pol.' *Hincks*, p. 278.)

1. Mastigophora Dutertrei, *Aud.* 'Brit. Mar. Pol.' p. 279, pl. xxxvii. figs. 1, 2.
2. „ Hyndmani, *Johnston, op. cit.* p. 281, p. xxxvii. figs. 3–6.
3. „ „ *var.* ensiformis (MS. ? *Miss Jelly*).
4. „ „ „ porosa, *Pourtalès.*

Family XXII. **Adeoneæ**, *Busk*, 'Chal. Rep.' p. 177.

'Zoarium erect or (rarely) incrusting, affixed either by a more or less flexible or unjointed, radicate, chitino-calcareous peduncle, or immediately attached to some flexible body, either with or without a contracted base. Bilaminar except when incrusting; foliaceous, expanded, and fenestrate, or branched, or lobate, or entire. Cells of two or usually three kinds, zoœcial, oœcial, avicularian. No oœcia of the usual type. On the front a median pore, usually simple and circular, sometimes irregularly fimbriate, or represented by a depressed perforated areola. Usually one or more sessile avicularia on the front. In the oœcial cells the pore in most cases is sub-oral, or placed immediately below the mouth, and usually a minute avicularium on each side. The wall of the zoœcial cells is punctate or entire; that of the oœcial always punctate.'—*Loc. cit.* p. 177.

This important family group is founded upon well marked structural peculiarities:—

1. The existence of three distinct forms of cells.
2. The entire absence of oœcia of the usual type.
3. The presence of a median pore or its equivalent.
4. In the presence of avicularian cells, which are wholly converted into 'vicarious avicularia.'

Mr. Busk enumerates several other important characters, but one deserves special notice :—

'It consists in the circumstance that in the entire group the avicularian mandibles, both large and small, always exhibit a projecting point or articular process at each end of the base, into or close to which the erector muscles are attached. To which may be added that, so far as I have noticed, the occlusor muscle of the mandible is always single instead of consisting of two bands as usual.'—*Busk*, *loc. cit.* p. 178.

The genus *Adeona* is the subject of a monograph by Dr. Kirchenpauer ('Ueber die Bryozoa, Gattung Adeona,' Hamburg, 1879), in which he enumerates eight forms which are regarded by him as species. These are as follows :—

1. Adeona foliacea or follifera, *Lamx.* and *Lamk.*
2. ,, intermedia, *Kirchenpauer.*
3. ,, macrothyris, *Kirchenpauer.*
4. ,, arborescens, *Kirchenpauer.*
5. ,, grisea, *Lamouroux.*
6. ,, cellulosa, *Macgillivray.*
7. ,, albida, *Kirchenpauer.*
8. ,, Wilsoni, *Macgillivray*, which has been added since the monograph was written.

Besides these published Mr. Busk says that he is acquainted from direct observation with five or six others 'that I have not been able to identify with any of the foregoing, and which will be included in a projected memoir on the genus, which I hope to be able shortly to prepare.'

9. Adeona appendiculata (n. sp.) Australia.
10. ,, Gattyæ (n. sp.) South Africa.
11. ,, lancifera (n. sp.) Australia.
12. ,, vulga (n. sp.) Australia.
13. ,, microthyris (n. sp.) Australia.
14. ,, lycopodioides (n. sp.) South Atlantic, *Busk*, 'Chal. Rep.' p. 179.

The first only appears in the 'Challenger' collection.

Genus 80. Adeona, *Lamouroux.*

Adeona, *Lamx.*, *Lamk.*, *Kirchenpauer.*
Dictyopora, *Macgillivray*, 'Nat. Hist. Vict.' Decade V.

'Zoarium erect, foliaceous, expanded, flabellate or lobate, fenestrate or entire, usually supported on a flexible or sub-flexible, chitino-calcareous, nearly jointed stem, composed of radicle tubes incrusted with calcareous matter and attached by spreading radical fibres. If without a stem generally attached to a flexible support.'—*Chal. Rep.* p. 181.

Adeona appendiculata, *Busk*, 'Chal. Rep.' pl. xxxiii. fig. 6, woodcuts, 47, 48, p. 182.

Genus 81. Adeonella, *Busk.*

'Zoarium erect, very variously branched or lobate, attached by a contracted base, or pedicle, often containing radical fibres, and affixed usually on a more or less flexible support.'—*Chal. Rep.* p. 183.

Only eight species of *Adeonella* occur in the 'Challenger' collection, but Mr. Busk has furnished a list of recent forms which he would be

inclined to include in the sub-genus as described above. In all probability there are many fossil forms that should be included in this group.

1. Adeonella tuberculata (n. sp.) = Eschara lichenoides, 'Brit. Mus. Cat.' (Not Milne-Edw.)
2. „ feugensis, *Busk.*
3. „ sulcata, *Milne-Edw.*
4. „ arcuata, *Busk*, MS.
5. „ lichenoides, *Milne-Edw.*
6. „ falciformis, *Busk*, MS.
7. „ megapora, *Busk*, MS.
8. „ dolichostoma (n. sp.), MS.
9. „ natalensis (n. sp.), MS.
10. „ crassa (n. sp.), MS.
11. „ Pallasii, *Heller.*
12. „ Helleri (n. sp. ?), MS.
13. „ dispar, *Macgillivray.*
14. „ mucronata, *Macgillivray.*
15. „ fissa, *Hincks.*
16. „ subsulcata, *Smitt.*
17. „ polymorpha, *Busk*, pl. xxi. figs. 1*a*, 2*a*, 3, 3*a*, not figs. 1 and 2, woodcut, p. 183.
18. „ platalea, *Busk*, 'Chal. Rep.' pl. xxi. figs. 4, 4*a*, excluding the branched figure, woodcut, p. 184
    = Eschara platalea, *Busk*, 'Brit. Mus. Cat.'
    = (?) Eschara hexagonalis, *Haswell*, 1881.
19. „ intricaria, *Busk*, 'Chal. Rep.' pl. xxi. fig. 2, woodcuts, 51 and 53, p. 185.
20. „ atlantica, *Busk*, 'Chal. Rep.' pl. xx. fig. 7, woodcut, 54, p. 186.
21. „ regularis, *Busk*, 'Chal. Rep.' pl. xx. fig. 2, and woodcut, 55, p. 186.
22. „ distoma (?) *Busk*, 'Chal. Rep.' p. 187, woodcuts, 56, 57
    = (?) Eschara coscinophora, *Reuss, Stolica & Manzoni*
    = (?) Porellina coscinophora, *D'Orb.*
    Lepralia distoma, *Busk*, 'Quart. Jour. Mic. Soc.'
    „ distoma, *Busk.*
23. „ *Var.* imperforata, *Busk*, 'Chal. Rep.' pl. xx. fig. 4.
24. „ pectinata, *Busk*, 'Chal. Rep.' p. 189, woodcut.

Genus 82. Reptadeonella, *Busk.*

'Challenger Report.' Referred to on pages 178 and 180, but not described. The genus will include—

1. Reptadeonella violacea
   = Lepralia *id.*
2. „ innominata (probably).

And several fossil forms.

Family XXIII. **Celleporidæ.**

Johnston, 'Brit. Mus. Cat.' *Hincks.*
Escharidæ (*pars*), *D'Orbigny.*
Myriozoidæ (*pars*), *Smitt.*

'Zoœcia urceolate, erect or sub-erect, irregularly heaped together, and often forming several superimposed layers.'—*Chal. Rep.* p. 190.

Genus 83. Cellepora.

Fabric., *Linn*, &c., 'Brit. Mus. Cat.' *Johnst.*, *Hincks.*
Celleporaria, *Lamx.*, *Reuss*, *D'Orb.*

'Zoarium multiform, lamellar and incrusting, partially adnate or free, or erect and attached by a thick base, massive and irregularly branched, solid or hollow, or in the shape of small parasitic housiform or discoid growths. Zoœcia in the older portions more or less erect or vertical, very irregularly disposed or heaped together. Orifice entire or sinuated in front, with or without internal denticles. A pre-oral rostral process (sometimes aborted), usually supporting an avicularium; very generally interspersed avicularia.'—*Challenger Rep.* p. 190.

Mr. Busk might well speak of this as a 'multiform and perplexing genus,' and I question very much that had it not been for the close study which he has given to the chitinous parts—of which he gives two plates—whether he would have been able to furnish such admirable details of species. Mr. Busk divides the genus into four sections:—

§ 1. Operculum sub-orbicular or semicircular, with a nearly straight lower border; avicularian mandibles with a short median columella.[1]

§§ *a. Lobate, branched, or massive.*

1. Cellepora hastigera, *Busk*, 'Chal. Rep.' pl. xxix. fig. 1, pl. xxxv. fig. 8.
2. „ tuberculata, *Busk*, 'Chal. Rep.' pl. xxviii. and pl. xxxv. fig. 7.
3. „ albirostris, *Smitt*, 'Chal. Rep.' pl. xxx. fig. 7, pl. xxxv. fig. 3
   = Discopora *id.* (forma typica), 'Florid. Bryoz.'
   (?) = Cellepora bispinata, *Busk*, 'Brit. Mus. Cat.' p. 87.
4. „ aspera, *Busk*, 'Chal Rep.' pl. xxviii. fig. 6.
5. „ columnaris, *Busk*, 'Chal. Rep.' pl. xxix. fig. 11, pl. xxxv. fig. 16.
6. „ honolulensis, *Busk*, 'Chal. Rep.' pl. xxix. fig. 5, and pl. xxxv. fig. 15.
7. „ imbellis, *Busk* (?) 'Chal. Rep.' pl. xxix. fig. 7, and pl. xxxv. fig. 20.
8. „ Jacksoniensis, *Busk*, 'Chal. Rep.' pl. xxx. fig. 10, pl. xxxv. fig. 9.
9. „ polymorpha, *Busk*, 'Chal. Rep.' pl. xxx. fig. 11.

§§ *β. Incrusting.*

10. „ apiculata,[2] *Busk*, 'Chal. Rep.' pl. xxix. fig. 2, pl. xxxv. fig. 12.
11. „ samboangensis, *Busk*, 'Chal. Rep.' pl. xxx. fig. 7 and pl. xxxv. fig. 10.
12. „ discoidea, *Busk*, 'Chal. Rep.' pl. xxx. fig. 8, pl. xxxv. fig. 1.

[1] 'This character,' says Mr. Busk, 'seems to be confined to species belonging to the southern hemisphere, as it is not present in the Mediterranean *Cellepora sardonica* and *Cellepora digitata*.'

[2] Figure from a bad specimen; chitinous parts all right.

13. Cellepora tridenticulata, *Busk*, 'Chal. Rep.' pl. xxix. fig. 3 and pl. xxxv. fig. 17.
14. „ vagans, *Busk*, 'Chal. Rep.' pl. xxix. fig. 10 and pl. xxxv. fig. 11.
15. „ mammillata, *Busk*, 'Brit. Mus. Cat.' p. 87.
    Var. atlantica, *Busk*, 'Chal. Rep.' pl. xxxv. figs. 4, 5, and 13.

§ 2. Operculum pedunculate or produced downwards, usually with an articular notch on each side. No median columella in the mandibles.

§§ *a. Lobate, branched, or ramose.*

16. Cellepora rudis, *Busk*, 'Chal. Rep.' pl. xxviii. fig. 7 and pl. xxxvi. fig. 7.
17. „ solida, *Busk*, 'Chal. Rep.' pl. xxix. fig. 12.
18. „ pustulata, *Busk*, 'Chal. Rep.' pl. xxviii. fig. 8.
19. „ cylindriformis, *Busk*, 'Chal. Rep.' pl. xxx. fig. 9, and pl. xxxvi. fig. 9.
20. „ Simonensis, *Busk*, 'Chal. Rep.' pl. xxix. fig. 9; pl. xxxvi. fig. 8, p. 200.
21. „ Eatonensis, *Busk*, 'Chal. Rep.' pl. xxix. figs. 4, 6, 8; and pl. xxxvi. figs. 3–5.
22. „ ovalis, *Busk*, 'Chal. Rep.' pl. xxviii. fig. 5; and pl. xxxv. fig. 6.

§§ *β. Pisiform.*

23. „ bicornis, *Busk*, 'Chal. Rep.' pl. xxx. figs. 1 and 12; and pl. xxxvi. figs. 13, 15.
24. „ bilabiata, *Busk*, 'Chal. Rep.' pl. xxx. fig. 2.
25. „ signata, *Busk*, 'Chal. Rep.' pl. xxx. fig. 3; and pl. xxxvi. fig. 14.
26. „ conica, *Busk* (?), 'Chal. Rep.' pl. xxviii. fig. 10; and pl. xxxvi. fig. 1
    = (?) Cellepora avicularis, *Smitt*, 'Florid. Bryozoa.'
27. „ ansata, *Busk*, 'Chal. Rep.' pl. xxx. fig. 4; and pl. xxxvi. fig. 17.
28. „ canaliculata, *Busk*, 'Chal. Rep.' pl. xxx. fig. 5; and pl. xxxvi. fig. 16.
29. „ bidenticulata, *Busk*, 'Chal. Rep.' pl. xxx. fig. 6; and pl. xxxvi. fig. 6.
29.* „ *Var.* subæqualis, *Busk*, 'Chal. Rep.' pl. xxxvi. fig. 11, chitinous parts.
30. „ granum, *Hincks*, 'Ann. Mag. Nat. Hist.' 1861, 'Chal. Rep.' p. 205, pl. xxxvi. fig. 10.
31. „ tubulosa, *Hincks* (sp.), 'Chal. Rep.' p. 205
    = C. Costarii, *var.* tubulosa, *Hincks*, 'Brit. Mar. Pol.,' 'Chal Rep.,' woodcut, p. 205.

In his 'British Marine Polyzoa' and Contributions in the 'Annals,' Mr. Hincks describes other species whose names are not found in the above list.

Cellepora pumicosa, *Linn.*, 'Brit. Mar. Pol.' p. 398, pl. liv. figs. 1–3. Widely distributed.
„ ramulosa, *Linn.* (*op. cit.* pl. lii. figs. 7–9).

Cellepora dichotoma, *Hincks* (*id.* pl. lv. figs. 1–6).
Var. a, attenuata, *Alder* (*id.* figs. 7–10).
„ avicularis, *Hincks* (*op. cit.* pl. liv. figs. 4–6).
„ tubigera *Busk* ('Crag Pol.'); *Hincks*, pl. liv. figs. 7–9.
„ armata, *Hincks* (*op. cit.* pl. liv. figs. 10–13).
„ Costazii, *Aud.* (*op. cit.* pl. lv. figs. 11–14).
Var. a, tubulosa, *Hincks* (see above, No. 31).
„ albirostris, *Smitt* (see No. 3, above), Hincks's 'Polyzoa of Bass's Straits.'
„ lævis, *Haswell* (Hincks's 'Polyzoa of Bass's Straits').

Family XXIV. **Selenariadæ**, *Busk.*

'Brit. Mus. Cat.' pl. i. p. 97.

'Zoarium orbicular or irregular in outline, convex on one side, plane or concave on the other; in the mature state probably free, often with a foreign particle, central or eccentric, on the concave face. Zoœcia immersed, flustrine.'—*Chal. Rep.* p. 206.

1. Genus Cupularia, *Lamouroux.*
2. Genus Lunularia, *Lamouroux.*

Genus 84. Cupularia, *Lamx.*

Cupularia, *Lamx.*, *Busk*, 'Brit. Mus. Cat.' p. 97.
Lunulites (pars), *Defrance* and *Auctt.*

1. Cupularia guineensis, *Busk*, 'Brit. Mus. Cat.' p. 98; 'Chal. Rep.' pl. xiv. fig. 6.
2. „ monotrema, *Busk*, 'Chal. Rep.' pl. xiv. fig. 5.
3. „ Owenii, *Gray*, 'Chal. Rep.' p. 207
= Lunulites *id.*, *Gray*
= Cupularia *id.*, *Busk*, 'Brit. Mus. Cat.'
= „ denticulata, *Conrad*
= Lunulites alveolatus (?), *S. Wood.*
4. „ Loweii, *Busk*, 'Brit. Mus. Cat.'
5. Stellata, *Busk* „ „
6. „ pyriformis, *Busk* „ „
7. „ canarienses, *Busk* „ „
8. „ Johnsonii, *Busk* „ „

Genus 85. Lunularia, *Lamouroux*

= Lunulites, *Lamx.*, 1821, 'Brit. Mus. Cat.'

'Zoœcia disposed in series, radiating from the centre and bifurcating as they advance towards the border; the vibracularia lying in linear series, alternating with those of the zoœcia. The chitinous vibraculum usually bifid or trifid at the extremity.'—*Chal. Rep.* p. 208.

Lunularia capulus, *Busk*, 'Brit. Mus. Cat.' p. 100; 'Chal. Rep.' p. 208, pl. xiv. fig. 7.
incisa, *Hincks*, 'Annals,' Aug. 1881, p. 127, pl. iv. figs. 1–3
= (?) Conescharellina, *D'Orb.*
gibbosa, *Busk*, 'Brit. Mus. Catalogue.'
cancellata, *Busk* „ „
philippinensis, *Busk* „ „

β. Part II.

Sub-order II. Cyclostomata, *Busk*

= Tubuliporina, *Milne-Edw.*, *Johnst.*, *Hagenow*, &c.
= Auloporina, Myrioporina (part), *Ehrnberg*
= Cenoporina (part), *Bronn*
= Centrifuginea (part), *D'Orbigny*

Group 1. Radicellata, *D'Orbigny.*

Zoarium erect, articulated, attached by radical tubes.

Family I. **Crisiidæ**, *Busk.*

'Crag Polyzoa,' p. 92, 1859; *Hincks*, 'Brit. Mar. Polyzoa'; *Busk*, 'Cyclostomata, 'Brit. Mus. Cat.' pl. iii.

In Professor Smitt's papers on the order Cyclostomata ('Scandinavian Bryozoa'), the family Crisiidæ is divided into two genera, *Crisidia*, Milne-Edwards, and *Crisia*, Lamouroux; and Mr. Busk follows this arrangement in the third part of his 'British Museum Catalogue' (Cyclostomata, 1875). Mr. Hincks in his 'British Marine Polyzoa,' and in his subsequent writings, disallows the genus *Crisidia*, Milne-Edwards, and I think wisely so. In his Cyclostomatous part of the 'Bay of Naples Bryozoa,' previous to the publication of Mr. Hincks's work ('Annals,' April 1879), Mr. A. W. Waters also adopted this arrangement. Mr. Hincks, however, divides the group into two series, α and β.

Genus 1. Crisia, *Lamx.* (part)

= Crisia, *Fleming*, *Blainville*, *Milne-Edwards* (part), *Johnston*, *D'Orbigny*, *Busk*, *Hincks*, *Waters*.
Falcaria (part), *Oken*.

Zoœcia in a single series or in two alternate series (*Hincks*). Oœcia irregularly placed (*Busk*).

1. Crisia cornuta, *Linnæus* = Sertularia *id.*, *Linn. Sys.* 1316
= Falcaria *id.*, *Oken*, *Gray*
= Crisia setacea, *Couch* = (?) Crisidea *id.*, *Sars*
= Unicellaria cornuta, *Blainv.*
Hincks, p. 419, pl. lvi. figs. 1–4; Busk, p. 3, pl. i. figs. 1–10.

Localities: Widely distributed round our coast.
Geographical Distribution: Mediterranean; Bay of Naples (rare); Scandinavia; Finland; Greenland; coasts of France; Houston-Stewart Channel; Virago Sound (common), *Hincks*.

2. Crisia cornuta, *var.* β, geniculata *Busk.* Without spines
= C. geniculata, *Milne-Edw.*, *Johnst.*, Sars
= C. cornuta (*var.*), *Smitt* (*sine cornibus*)
= Filicrisia geniculata, *D'Orb.*
Localities: Both shores of the British Channel.
Geogr. Distrib.: Roscoff; Mediterranean; Bahusia; Norway.

3\. Crisia eburnea *Linn.*= Sertularia *id. Linn.*
= Crisia eburnea, authors generally.
(?) C. Haueri, *Reuss* (*fide* Manzoni)
= Crisia (group A), Vine, 5th ' Rep. Foss. Polyzoa,' 1884.
Localities: Generally distributed, British seas.
Geogr. Distrib.: North and Arctic Seas; St. Lawrence; Labrador; St. George's Banks; California; Fiji Islands; New Zealand; Australia; Virago Sound (Queen Charlotte Islands); Madeira; Mediterranean.

4\. „ eburnea, *var. α*, aculeata, *Hassall.*
British localities: Kingstown Harbour; Brighton (*Hassall*); Antrim; Ayrshire; Shetland (see *Hincks*, pp. 420–1 pl. lvi. figs. 5, 6, woodcut, fig. 21, p. 416. *Busk*, ' Cyclostomata,' p. 4, pl. ii. figs. 1, 2, pl. v. figs. 1, 2, 5).

5\. „ eburnea, *var. β*, producta, *Smitt.*
The position of this form is doubtful. Norman refers it to *eburnea*; Smitt places it between the two. Mr. A. W. Waters (' Bay of Nap. Bry.') ranks it as a distinct species, and remarks: ' As there are connecting links between this and *cornuta* it might be called *C. cornuta* var. *producta*, or even *C. geniculata*, var. *producta*.' In his description, however, Mr. Waters says the ' ovicell axillary.' Mr. Hincks, ' Brit. Mar. Pol.' places it as above. Mr. Busk (' Cyclostomata,' p. 10) says, ' Probably only a variety of *C. cornuta* (*vide* pl. i. fig. 3); it does not appear to have any character in common with *C. eburnea*.'
Locality: Shetland, 100 to 170 fathoms.
Geogr. Distrib: Naples littoral (rare); Scandinavia; Nova Zembla, 5 to 10 fathoms.

6\. „ denticulata, *Lamk.*= Cellaria *id. Lamk.*
= C. luxata, *Flem.*, *Blainv.*, *Johnst.*, *Couch*
= Crisia and Cellaria arctica, *Sars*
= (?) Crisia attenuata, *Heller* (*fide Hincks*).
Hincks, p. 422, pl. lvi. figs. 7–9.
Busk, p. 4, pl. ii. figs. 3, 4, pl. iii. figs. 1–6, pl. iv. figs. 1–4.
Waters (' Bay of Nap. Bry.' ' Ann.,' Ap. 1879), p. 269 pl. xxii. fig 2.
Localities, Brit.: Very generally distributed.
Geogr. Distrib.: Roscoff; Adriatic (*Heller*); Madeira; South Africa (*Busk*); Norway; Spitzbergen; Kara Sea; Grand Manan (Busk says?); Houston Stewart Channel (*Hincks*); Franz Joseph Land (*S. O. Ridley*).

7 „ fistulosa, *Heller* (non *Busk*) Adriatic
= (?) C. eburnea (pars *Smitt*), *A. W. Waters.*
= C. Haueri, *Reuss* (*A. W. Waters*, ' Bry. Bay Nap.')
= (?) C. eburnea, *Manzoni* (see No. 3, ' Bry. Bay Nap.,' *Waters*, pl. xxiii. fig. 3. ' Prof. Heller's comparison with *C. geniculata* would be very inappropriate for the *C. fistulosa* of Busk, *A. W. Waters.*
Loc.: Naples; Adriatic? (*Heller*).

8. Crisia fistulosa, *Busk* (non *Heller*), 'Cyclostomata,' pl. via. figs. 1, 2.
Loc.: Lissa; Lagorta; Adriatic? *Busk*, pl. via. figs. 1, 2, p. 5 ('Cyclostomata').
9. " elongata M.-Edw. = C. attenuata, *Heller* (*Waters*) = Cellaria elongata, M.-Edw., *D'Orb.*
Loc.: Adriatic (*Hincks*); Naples, 40 fathoms (*Waters*); Red Sea? (M.-Edw.); Algoa Bay. *Busk*, pl. iv. figs. 5, 6, p. 5. *Waters*, pl. xxiii. fig. 1, p. 269.
10. " elongata, *var.* angustata, *Waters*, pl. xxiii. fig. 4. 'Bry. Bay Nap.,' Ap. 1879, p. 269.
There seems to be much difference of opinion respecting *Crisia elongata* and its varieties. My own specimens from South Africa differ from Mediterranean specimens even from the same depths as Mr. Waters's deep and shallow water forms. Mr. Waters gives the following synonyms, which, at present, I cannot accede to: *C. fistulosa*, Busk; (?) *C. Edwardsii*, Reuss; (?) *C. Edwardsii*, Manzoni.
11. " Edwardsiana, *D'Orb.*, *Busk*, p. 5, pl. ii. figs. 5–8.
= (?) Bicrisia Edwardsiana, *D'Orb.*, 1852
= Crisidia Edwardsiana, *D'Orb.*, 1839, 'Voy. dans. l'Amér.'
Geogr. Distrib.: Coasts of Patagonia, *D'Orb.*; Tierra del Fuego, *Darwin*; New Zealand, *Dr. Sinclair*; Australia, *Macgil.*

Mr. Busk says: 'D'Orbigny's figure represents the zoœcia as much longer and more slender than his own specimens; but he has retained his name because he has but little doubt about the identity of his own and D'Orbigny's species.'

12. Crisia eburneo-denticulata *Smitt* (MS.), *Busk*, pl. vi.
= Crisia eburnea (*var.*) *Smitt.*
Loc.: Spitzbergen, 70–96 fathoms.
13. " acropora, *Busk*, pl. v. figs. 3, 4, *Id.*, 'Voy. of Rattles.,' vol. i. p. 351.
Loc.: Bass's Straits, 47 fathoms.
14. " margaritacea, *Busk*, pl. vi. *b*, fig. 1
= C. denticulata, *Busk*, 'Voy. of Rattles.'
Loc.: Australia, 'Voy. of Fly,' *Jukes.*
15. " Sinclairensis, *Busk*, pl. iv. figs. 7–11. *Loc.*: Coast of Patagonia (*Dr. Sinclair*).
15*. " Holdsworthii, *Busk*, pl. vi. *a*, fig. 2. *Loc.*: Pearl-oyster Bank, Ceylon (*Holdsworth*).
16. " conferta, *Busk*, pl. vi. *a*, fig. 5. *Loc.*: Cape Verd Islands (H.M.S. *Herald*).
17. " tubulosa, *Busk*, pl. vi. *a*, figs. 3, 4. *Loc.*: Cape Verd Islands (H.M.S. *Herald*).

These are the whole of the species of *Crisia* illustrated by Mr. Hincks, Mr. Busk ('Cyclostomata'), and Mr. Waters ('Bay of Nap. Bry.'). Mr. Busk, however, gives a list of other recent forms noticed by authors (see 'Cyclos.' pp. 7 to 9).

18. Crisia sertulariodes, *D'Orb.* = Probiscina *id. Aud.* *Loc.*: Red Sea (?). May be C. fistulosa, *Heller.*
19. „ patagonica, *D'Orb.*, 'Voy. Amér. Mérid.' *Loc.*: Patagonia.
20. „ sinensis, *D'Orb.*, 'Pal. Fr.' = (?) C. elongata, *M.-Edw.* *Loc.*: Hongting.
21. „ martinicensis, *D'Orb.*, 'Pal. France.' *Loc.*: Martinique.
22. „ californica, *D'Orb.*, 'Pal. France.' *Loc.*: Lower California.
23. „ punctata, *D'Orb.* (?) = *C. Sinclairensis* (15). *Loc.*: Ile de Venado, Mer Vermeille, California.
24. „ attenuata, *Heller.* *Loc.*: Adriatic (*Lesina*).
25. „ recurva, *Heller.* *Loc.*: Adriatic (*Lesina*).
26. „ setosa, *Macgil.* ('Australian Pol.' p. 16). *Loc.*: Australia.
27. „ biciliata, *Macgil.* Having seen a specimen of this species I think it ought to be kept distinct from C. Edwardsiana, *D'Orb.*
28. „ producta, *Smitt.* *Loc.* (*Smitt*): Scandinavia (as C. eburnea, *Norman*); Shetland.
29. „ tenuis, *Macgillivray.* *Loc.*: Australia.

Group II. Incrustata, *D'Orb.*

Zoarium calcareous, continuous, not divided by corneous joints, or furnished with radicle tubes; erect and attached by a contracted base, or recumbent and immediately adnate, either wholly or in part.

This division is accepted by Mr. Busk in his catalogue of the Cyclostomata ('Brit. Mus.' pt. iii.), and in nearly the same words, only the arrangement is different from that of Mr. Hincks.

Family II. **Tubuliporidæ.**

'Zoarium entirely adherent, or more or less free and erect, multiform, often linear, or flabellate or lobate, sometimes cylindrical. Zoœcia tubular, disposed in contiguous series or in single lines. Oœcium an inflation of the surface of the zoarium at certain points or a modified cell.'—*Hincks*, 'Brit. Mar. Polyzoa,' p. 424.

1. Stomatopora, *Bronn.*
2. Tubulipora, *Lamarck.*
3. Idmonea, *Lamouroux.*
4. Entalophora, *Lamx.*
5. Diastopora, *Lamx.* (part).

Genus 2. Stomatopora, *Bronn.*

'Brit. Mus. Cat.' *Busk*, as *Alecto*, pp. 23, 24.
'Brit. Marine Polyzoa,' *Hincks*, as *Stomatopora*, p. 424.
'Fifth Rep. Foss. Polyzoa,' 1884, as *Stomatopora*, which see for description and fossil species.

1. Stomatopora granulata, *M.-Edw.*
 = Alecto *id.*, *Johnston* (pt.)
 = Stomatopora incrassata, *D'Orb.*
 = (?) Alecto parasita, *Heller.*
 Localities.: Several British from Shetland to Cornwall.
 Geogr. Distrib.: Roscoff (*Joliet*); Bergen, *Hincks*, pl. lvii. figs. 1, 2; *Busk*, pl. xxxii. fig. 1.

2. Stomatopora major, *Johnston*, *Hincks*, pl. lviii. and pl. lxi. fig. 1
= Alecto *id.*, *Busk*, pl. xvii. figs. 3–5; pl. xvi. fig. 3 (?)
= (?) Tubulipora trahens, *Couch*
= (?) ,, repens, *S. V. Wood* = Alecto, *Busk*, 'Crag Pol.' Other synonyms given by Busk with (?).
Localities: Several Brit.: Cornwall; Northumberland; Antrim; Isle of Man; Shetland; Guernsey.
Geogr. Distrib.: Bergen; Roscoff (*Hincks*); Scandinavian and Arctic seas (*Busk*).

3. ,, dilatans, *Johnst.* (*Hincks*, pl. lvii. figs. 3, 3*a*)
= Alecto *id.*, *Busk*, pl. xxxii. fig. 2
= (?) Diastopora repens (part), *Smitt*
= Alecto *id.*, *Manzoni*, 'Castrocaro'
= S. dilatans, *Vine*, 'fifth Brit. Assoc. Rep.' 1884, for other particulars.
Localities: Several northern British.
Geogr. Distrib.: Roscoff; Scandinavian coast, great depths.

4. ,, Johnstoni, *Heller* (*Hincks*, pl. lix. fig. 1; pl. lx. figs. 1, 1*a*)
= Criserpia *id.*, *Heller*
= (?) Alecto granulata, *Johnst.*
Localities: Guernsey; coast of Antrim.
Geogr. Distrib.: Mediterranean; Adriatic (*Heller*).

5. ,, expansa, *Hincks*, pl. lxii. fig. 1
= (?) Proboscina ramosa, *D'Orb.*
= Idmonea cenomana, *D'Orb.*
Locality: On dead shells, Isle of Man (*Hincks*).

6. ,, incurvata, *Hincks*, pl. lxiv. figs. 6–8.
Localities: Coast of Antrim (abundant); Hebrides; off Caithness; Guernsey.

7. ,, diastoporides, *Norman* (*Hincks*, pl. lxiii. figs. 3, 4)
=Alecto *id.*, *Norman*, Shetland, 'B. A. Rep.' 1867.
Localities: Shetland, 70–110 fathoms; Wick; off the Maiden lighthouses, Co. Antrim, 62–72 fathoms.
Geogr. Distrib.: Gulf of St. Lawrence; off Hare Island, Baffin's Bay, 175 fathoms ('Valorous' dredging).

8. ,, compacta, *Norman* (*Hincks*, pl. lxiii. figs. 1, 2).
Localities: Hebrides; The Minch; Shetland.
(Sub-genus Proboscina, *Smitt*)

9. ,, incrassata, *Smitt* (*Hincks*, pl. lix. figs. 2, 3)
=Tubulipora, *id.*, *Smitt*
=Alecto retiformis, *Hincks*, 'Supplement Devon and Cornwall Polyzoa.'
= (?) Filisparsa incrasata, *D'Orb.*
Localities: Several Brit.: Salcombe Bay; Cornwall; Guernsey; Shetland.
Geogr. Distrib.: Bahusia, in great depths; Spitzbergen; Nova Zembla; Kara Sea.

10. Stomatopora deflexa, *Couch* (*Hincks*, pl. lvii. fig. 4)
=Tubulipora *id.*, *Couch*
=Pustulipora *id.*, *Johnst.*, *Hincks*, (?) *Heller.*
Localities: Polperro; Mevagissey Bay; Wick; Peterhead; Shetland.
Geogr. Distrib.: Roscoff (*Joliet*).

11. „ fungia, *Couch* (*Hincks*, pl. lvii. figs. 5, 6)
=Tubulipora penicillata, *Johnst.*, *Landsb.*, *Alder*, *Hincks* (not *Fabric.*).
Localities: From Eddystone Lighthouse to Deadman Point; Polperro; Torbay; Wick and Peterhead; Banff.
Geogr. Distrib.: Finmark, 50 fathoms; Greenland; Hamilton's Inlet, Labrador.
Mr. Busk, in his 'Cyclostomata,' p. 26, pl. xxxii. fig. 3, describes and figures this species as Tubulipora fungia, *Couch.*

12. „ fasciculata, *Hincks*, p. 441, pl. lix. figs. 4, 5.
Locality: Coast of Antrim.

Genus 3. Tubulipora, *Lamk.*

Johnston, *Milne-Edw.*, *D'Orbigny*, *Busk.*
Ceriopora (pt.), *Hagenow*; Phalangella (sp.), *Gray.*
Obelia (sp.), *Lamx.*; Reptotubigera, *D'Orb.*
Tubulipora, *Vine*, 'Fifth Brit. Assoc. Rep.,' which see for several fossil species.

1. Tubulipora lobulata, *Hassall* (*Hincks*), pl. lxi. figs. 4, 5
=T. serpens (*pars*), *Busk*, 'Brit. Mus. Cat.' pl. iii.
Localities: British: Dublin Bay; Isle of Man; Torbay; Hastings. Scotland: Shetland.
Geogr. Distrib.: Scandinavian Coasts.

2. „ flabellaris, *Fabric.*, *Hincks*, pl. lxiv. figs. 1–3
=T. phalangea, *Couch* (*Busk*, 'Cat.' pt. iii. pl. xxiii.)
Localities: Cornwall; South Devon; Whitehead, Co. Antrim; Shetland.
Geogr. Distrib.: Bahusia; Bergen; Spitzbergen; Greenland; (?) South Labrador; Adriatic.

3. „ fimbria, *Lamk.* (*Hincks*, pl. lx. figs. 3, 3*c*)
=T. flabellaris, *Johnst.* (*Busk*, 'Cat.' pt. iii. pls. xxiv., xxv.)
Localities: Wick and Peterhead; Northumberland; Shetland.
Geogr. Distrib.: Greenland; Labrador; Gulf of St. Lawrence; Spitzbergen; Nova Zembla.

In his 'Brit. Mus. Catalogue,' pt. iii. Mr. Busk gives the following as Tubulipora:—

4. Tubulipora ventricosa, *Busk*, pl. xxxii. fig. 4
=T. incrassata, *var. a*, forma erecta, *Smitt; Busk*, 'Quart. Jour. Mic. Soc.' vol. iii. p. 256.
Geogr. Distrib.: W. Greenland (H.M.S. *Sophia*); Arctic and Norwegian seas; Spitzbergen.

5. Tubulipora pyriformis, *Busk*, 'Cat.' pt. iii. p. 27 (no plate).
Geogr. Distrib.: Tasmania.

From other authors (Busk's authority) :—

6. Tubulipora organizans, *D'Orb.*, 'Voy. dans l'Amér. Mérid.' p. 19, pl. ix. figs. 1–3.
Geogr. Distrib.: Falkland Islands.
7. „ dichotoma, *D'Orb.*, *id.*, p. 19, pl. ix. figs. 7, 31.
Geogr. Distrib.: Falkland Islands (? Proboscina).
8. „ malacensis, *D'Orb.*, 'Pal. France,' p. 847.
Geogr. Distrib.: Straits of Malacca.
9. „ capitata, *Hincks*, 'Annals,' Aug. 1881.
10. „ perfragilis, *Hincks*, 'Annals,' March 1884.
11. „ Dawsoni, *Hincks*, pl. ix. fig. 5.
12. „ fasciculifera, *Hincks*, pl. ix. fig. 6.

The above three species (10–12) are described by Mr. Hincks in his paper On the Polyzoa of Queen Charlotte Islands, 'Ann. Mag. Nat. Hist.' March 1884. No. 10 not figured.

Genus 4. Idmonea, *Lamouroux*.

See *Hincks* and *Busk* for synonyms; *Vine*, 'Fifth Brit. Assoc. Report,' for particulars of fossil species and special details.

1. Idmonea atlantica, *E. Forbes*; *Hincks*, pl. lxv. figs. 1–4; *Busk*, 'Brit. Mus. Cat.' pt. iii. pl. ix.
= I. radians, *Van Beneden*.
Var. a, tenuis, *Busk*.
Localities: British: Zetland seas; Outer Haaf; Hebrides.
Geogr. Distrib.: Naples; Hammerfæst (*Sars*); Grotsund; Norway; Frederickshaab; Baffin's Bay (entrance); Nova Zembla; Kara Sea.
Variety: North Atlantic; Florida; Madeira.
2. Idmonea serpens, *Linn.*; *Hincks*, pl. lxi. fig. 23; pl. lx. fig. 2
= Tubulipora serpens, *Busk*, *op. cit.* p. 25, pl. xxii.
Var. a, radiata, *Hincks*.
Localities: Generally distributed. *Var. a*, Cornwall.
Geogr. Distrib.: S. W. France; Mediterranean (*Lamx.*, *Heller*); Naples; Scandinavian Coast, Bahusa to Finmark.

The following are additional species compiled from Mr. Busk and other authorities, 'Cyclostomata,' 'Brit. Mus. Cat.' pt. iii.

3. Idmonea radians, *Lamk.*, *Busk*, *op. cit.* pl. vii. figs. 1–4.
Geogr. Distrib.: Australian seas abundant; New Zealand.
4. „ Milneana, *D'Orb.*, *Busk.*, *op. cit.*
= (?) I. transversa, *Milne-Edw.*
Geogr. Distrib.: Iles Malouines, *D'Orb.*; coast Tierra del Fuego; Patagonia; Chonos Archipelago (*Darwin*).

5. Idmonea contorta, *Busk, op. cit.* p. 12, pl. viii.
   Geogr. Distrib.: Algoa Bay, South Africa.
6. „ notomala, *Busk, op. cit.* pl. xii. a.
   Geogr. Distrib.: Rasel Amousth., Mediterranean (H.M.S. 'Porcupine').
7. „ marionensis, *Busk, op. cit.* pl. xiii. figs. 3, 4; pl. vii. figs. 7, 8 (young state).
   (?) Crisina hocstetteriana, *Stoliz*, and 'Florid. Bryozoa,' *Smitt.*
   Geogr. Distrib.: Marion Island; ? Gulf of Florida; Orakei Bay, Auckland, New Zealand.
8. „ irregularis, *Meneghini, op. cit.* pl. xii.
   Geogr. Distrib.: Adriatic; Dalmatian coast; Mediterranean (H.M.S. 'Porcupine').
9. „ parasitica, *Busk, op. cit.* pl. x. figs. 2, 3.
   Geogr. Distrib.: South Australia.
10. „ gracillima, *Busk, op. cit.* pl. vii. figs. 5, 6.
   Hab.: Atlantic Ocean, 286–322 fathoms (H.M.S. 'Porcupine').

Other recent species noticed by authors (*Busk*):—

11. Idmonea frondosa, *Meneghini.* Adriatic Sea.
12. „ gracilis „ „
13. „ serpula, *Heller* „
   Probably identical with No 11.
14. „ Meneghinii, *Heller.* Adriatic Sea.
15. „ triforis, *Heller.* „
16. „ tubulipora, *Meneghini.* „
17. „ dilatata, *D'Orb.* Ile de Ré.
18. „ angustata, *D'Orb.* Newfoundland.
19. „ rustica, *D'Orb.*
   Geogr. Distrib.: Manilla; Hongkong; Macao; Chasan Archipelago (*D'Orb.*).
20. „ tuberosa, *D'Orb.* Isl. de Basilan
   = (?) I. marionensis, *Busk.*
21. „ canariensis, *D'Orb.* Teneriffe
   = (?) I. gracillima, *Busk.*
22. „ californica, *D'Orb.*
   Geogr. Distrib.: Ile de Venado; Mer Vermeille; California.
23. „ fenestrata, *Busk,* 'Crag Polyzoa.' ? Spitzbergen, 50 fathoms.
24. „ australis, *Macgil.* Australia.

Genus 5. Entalophora, *Lamouroux*

= Pustulopora (part), *Blainv., Milne-Edw., Busk*

= Entalophora, *Vine.* Fifth 'Brit. Assoc. Rep.' for details and fossil forms.

1. Entalophora clavata, *Busk, Hincks,* pl. lxv. figs. 5–8
   = Pustulopora *id., Busk,* 'Crag Polyzoa'
   = Pustulopora deflexa (part), *Hincks.*
   Loc.: Wolf Rock, near Penzance; Torbay; coast of Antrim.

The only British species according to Hincks.

The following species under the name of Pustulopora, *Blainv.*, are given by *Busk* ('Catalogue,' pt. iii.) :—

2. Entalophora delicatula, *Busk*, *op. cit.* p. 20 (no plate).
Geogr. Distrib.: Australia; Cape Capricorn; ? Madeira.
3. „ australis, *Busk*, *op. cit.* pl. xvii. a., left-hand figure.
Geogr. Distrib.: Bass's Straits, 45 fathoms. Australian seas.
4. „ parasitica, *Busk*, *op. cit.* pl. xvii. figs. 1, 2.
Geogr. Distrib.: Bass's Straits; New Zealand.
5. „ proboscidea, *E. Forbes*, *op. cit.* pl. xvii. a., right-hand figure).
Geogr. Distrib.: Shetland seas; Mediterranean; Adriatic; Teneriffe and Canaries; Madeira.
6. „ clavæformis, *Busk*, *op. cit.* pl. xiv.
Geogr. Distrib.: Algoa Bay, South Africa.
7. „ intricaria, *Busk*, *op. cit.* pl. x. figs. 1 (part) and 4.
Geogr. Distrib.: South Australia.

From other authors (*Busk*) :—

8. Entalophora gallica, *D'Orb.*
Geogr. Distrib.: Coast of France; Ile de Ré; Calvados (shore); Newfoundland.
9. „ indica, *D'Orb.* Strait of Malacca.
10. (?) „ orcadensis, *Busk* = Hornera violacea, *Sars.*
Will be referred to again as Hornera.

Genus 6. Diastopora, *Lamx.*

For references to fossil forms and special details, see Remarks, &c., 'Brit. Assoc. Rep. on Fossil Polyzoa,' No. 5, 1884.

Genus Diastopora (part), *Lamx.*

= Patinella (sp.), *Busk*, *Hincks*
= Discosparsa, *D'Orb.*
= Mesenteripora, *Busk*, for foliaceous bilaminate forms.

1. Diastopora patina, *Lamk.* (*Hincks*, pl. lxvi. figs. 1–6). *Busk*, 'Brit. Mus. Cat.' pt. iii. pl. xxix. figs. 1, 2; pl. xxx. fig. 1
= Patinella verrucaria, *Gray*
= Discoparsa marginata, *D'Orb.*
= „ patina, *Heller*
= Diastopora patina, *Smitt.*
Loc.: British, very common, and fairly distributed.
Geogr. Distrib.: Roscoff; S.W. France; Adriatic; North and Arctic Seas; Bahusia; South Norway; Finmark (*Sars*); South Labrador.
2. „ obelia, *Johnst.* (*Hincks*, pl. lxv. figs. 10, 10*a*); *Busk*, *op. cit.* pl. xxvi. *Smitt*; *Heller.*
D. hyalina, *var.* *α*, obelia, *Johnst.*, *Smitt.*
? Berenicea hyalina, *Fleming.*
Localities: British, widely distributed.
Geogr. Distrib.: Guernsey; Jersey; North Sea and Arctic Ocean; Norway; Spitzbergen; Adriatic; Naples.

3. Diastopora sarniensis, *Norman* (*Hincks*, pl. lxvi. figs. 7–9)
= D. hyalina (part), *Smitt.*
Localities: Guernsey and Jersey; Cornwall; Hastings.
Geogr. Distrib.: ? Red Sea or Mediterranean.

4. „ suborbicularis, *Hincks*, pl. lxvi. figs. 11, 11*a*
= D. simplex, *Busk*, *op. cit.* pl. xxix. figs. 3, 4, and 'Crag Polyzoa.'
Localities: South Devon; Isle of Man, &c.
Geogr. Distrib.: Naples; Bahusa; Finmark; Kara Sea; Greenland.

The above four are the whole of the British species given by Mr. Hincks. Mr. Busk gives another species—

5. „ congesta, *D'Orb.*, *Busk*, *op. cit.* pl. xxxi. fig. 5.
Geogr. Distrib.: Mediterranean; African shore (H.M.S. 'Porcupine').

β. Foliaceous and bilaminate.

6. „ (Mesenteripora) meandrina, *Wood.*
The only locality, Greenland.

Family III. **Horneridæ**, *Smitt.*

Hincks, 'Brit. Mar. Polyzoa,' p. 467
= Crisinidæ (pt.), *D'Orb.* ? = Idmoneidæ (pt.), *Busk.*

Genus 7. Hornera, *Lamouroux*
= Siphodictum, *Lonsdale.*

1. Hornera lichenoides, *Linn.*, *Hincks*, pl. lxvii. figs. 1–5
= *Id.*, *Busk*, *op. cit.* pl. xviii. figs. 5, 6
= H. borealis, *Busk*, 'Crag Polyzoa.'
Localities: Shetland; Outer Haaf; Hebrides.
Geogr. Distrib.: Waderöarne, Bahusia; Norway; Nova Zembla; Kara Sea; Greenland; St. George's Banks.

2. „ violàcea, *Sars* (*Hincks*, pl. lxvii. figs. 6–8; pl. lxii. figs. 2, 3); *Busk*, *op. cit.* pl. xviii. figs. 1–4
= Pustulopora orcadensis, *Busk.*

Busk gives the following varieties:—
Var. α, proboscinna, pl. xviii. figs. 1–3.
„ *β*, tubulosa, pl. xviii. figs. 2–4.
Locality (for normal form): Shetland.
Geogr. Distrib.: Arctic Sea; coast of Norway.

Mr. Busk, also in his 'British Museum Catalogue,' part iii., gives the following in addition to the above:—

3. „ frondiculata, *Lamx.*, *op. cit.* pl. xx. figs. 1, 2, 3, 6.
Geogr. Distrib.: Mediterranean; Adriatic, abundant.

4. „ cæspitosa, *Busk*, *op. cit.* pl. xv.
Geogr. Distrib.: Cape Capricorn; Tierra del Fuego.

5. „ pectinata. *Busk*, *op. cit.* p. 18.
Geogr. Distrib.: Madeira.

6. „ tubulosa, *Busk*, *op. cit.* p. 19. Only described, no references or plate.

7. Hornera foliacea, *Macgil.*, *op. cit.* pl. xiii. figs. 1, 2; pl. xix.
= Retihorneri, *id.*, *Busk*, *op. cit.*
Geogr. Distrib.: South Australia.
8. „ robusta, *Macgil.* Australia.

Since the early—and now classical—labours of Mr. Busk on this peculiar genus, much has been added to our knowledge respecting species of the genus, but rather by way of suggestion as to its classificatory position. In the 'Crag Polyzoa,' 1859, *Hornera* takes its place as the first genus in the *Idmoneidæ* of Busk. In his descriptions (p. 95) Mr. Busk speaks of both recent ramose and fenestrate species.

Ramose 1. Hornera frondiculata, *Lamx.*
„ 2. „ borealis (MS.), *Busk.*
„ 3. „ tridactylites (MS.), *Busk.*

The first a Mediterranean form; the second collected on the coast of Norway by Mr. McAndrew; and the third by Mr. Darwin on the shores of Patagonia and Tierra del Fuego, and by Mr. Macgillivray in the Australian seas.

Of the fenestrate kinds Mr. Busk at that time was acquainted with two forms—'apparently distinct species, both of which I believe to be, and one certainly is, Australian. No account of this species, of which very perfect specimens were brought by Mr. Gould from South Australia, has yet been published, although figures of it have been prepared. I propose to call it Hornera Gouldiana' (*Busk*, 'Crag Polyzoa, p. 95). The Hornera borealis of above is the H. lichenoides, *Linn.*, of the Cyclostomata ('Brit. Mus. Cat.' p. 17).

In the 'British Marine Polyzoa' Mr. Hincks established the family Horneridæ for the reception of the two British species already given, remarking that that 'Hornera is connected with the Tubuliporidæ through Idmonea, to which it bears in many points a very close resemblance. It embraces two very characteristic groups, one of which may be represented by H. lichenoides, in which the zoœcia are covered in front by a calcareous crust, which takes the form of wavy longitudinal ridges,' and H. violacea, in which the superficial crust is wanting (*op. cit.* pp. 469, 470).

In remarking on the fossil species of Macgillivray's *Hornera folicea* Mr. Waters ('Quart. Jour. Geol. Soc.' p. 688, vol. xl.) draws attention to the 'transverse tubules' of the species, but his remarks on his sections are too brief for special work. After examining some very fine specimens of the Australian *Hornera* both in the bulk and in section, I may be allowed to say that for other purposes than for the mere description or diagnosis of recent forms these Australian species may be conveniently studied, more especially so if only to dispel the idea of the supposed identity of species of *Fenestella* or *Polypora* with recent *Hornera*. The structure is most peculiar and interesting, whether we select for illustration the superficial features only or the tubular cells with their intervening tubules, as referred to by Mr. Waters.

Family IV. **Lichenoporidæ**, *Smitt.*

Hincks, 'Brit. Mar. Polyzoa,' p. 471
= Discoporellidæ, *Busk*, *op. cit.* p. 30.

Lichenoporidæ, *Vine*, 'Fifth Brit. Assoc. Rep. Foss. Polyzoa' for special details and fossil species.

Genus 8. Lichenopora, *Defranc.*

= Discoporella, *Gray, Busk.*

For other synonyms, see *Hincks* and *Busk.*

a. Colony simple.

1. Lichenopora hispida, *Flem.* (*Hincks*, pl. lxviii. figs. 1–8)
= Discoporella, *id.*, *Busk*, *op. cit.* pl. xxx. fig. 3.
Var. a, Meandrina, *Peach* (*Hincks*, woodcut, p. 475).
,, *β*, *Hincks.*
Localities: South Coast of Britain; Isle of Man; Hebrides; Shetland; St. Andrew's; Northumberland; Guernsey.
Var. a, Shetland, 170 fathoms.
Geogr. Distrib.: Bahusia; Norway; Finmark; Greenland; South Labrador; France.

2. ,, radiata, *Aud.* (*Hincks*, pl. lxviii. figs. 9, 10)
= Discoporella radiata, *Busk*, *op. cit.* pl. xxxiv. fig. 3.
Localities: South Devon; Brixham; Salcombe.
Geogr. Distrib.: Mediterranean; Adriatic; Naples.

3. ,, verrucaria, *Fabric.* (*Hincks*, pl. lxiv. figs. 4, 5)
= Discoporella, *Busk*, *op. cit.* p. xxviii. figs. 2, 3
= (?) Disparsa hispida, *Heller*
= (?) Tubulipora hispida, *Johnston*
Localities: Orkney (*Barlee*); Arran (*Busk*); co. Down (*Hyndman*).
Geogr. Distrib.: Bahusia; Norway; Finmark; Davis' Straits, 100 fath.; Reykiavik; Hamilton's Inlet, Labrador; Assistance Bay, Greenland; Bay of Fundy; St. George's Banks; Nova Zembla; Malotschkin-scharr; Kara Sea.

4. ,, regularis, *D'Orb.* (*Hincks*, pl. lxviii. fig. 11).
= Actinopora *id.*, *D'Orb.*
Locality: Shetland.

The above are the whole of the British species given by Mr. Hincks. The following list is compiled from Mr. Busk's 'Cyclostomata,' and from other authorities, all as *Discoporella* from Mr. Busk.

5. Lichenopora algoensis, *Busk*, *op. cit.* pl. xxviii. figs. 1–4.
Geogr. Distrib.: Algoa Bay, on *Catenicella*.

6. ,, ciliata, *Busk*, pl. xxx. fig. 6.
Geogr. Distrib.: Cape of Good Hope, on *Retepora*; New Zealand, on *Hornera*.

7. ,, Novæ-Zelandiæ, *Busk*, pl. xxx. fig. 2.
Geogr. Distrib.: Chonos Archipelago; Tierra del Fuego; Cape Horn; Chiloe; Tasmania.

8. ,, californica, *D'Orb.*, pl. xxx. fig. 5
=Unicavea, *id.*, *D'Orb.*
Geogr. Distrib.: San Diego, California; off Milva Maura, San Pedro, California.

9. Lichenopora mediterranea, *Blainv.*, *Busk*, pl. xxiv. fig. 4
=Actinopora *id.*, *D'Orb.*, and Unicavea, *id.*, *D'Orb.*
Geogr. Distrib.: Mediterranean.

10. „ Holdsworthii, *Busk*, pl. xxx. fig. 4.
Geogr. Distrib.: Ceylon.

Noticed by *Busk*, but no figures given.

11. „ convexa, *D'Orb.*=Unicavea, *id.*, *D'Orb.*
Geogr. Distrib.: Coast of Calvados.

12. „ Novæ-Hollandiæ, *D'Orb.*=Unicavea, *id.*
Geogr. Distrib.: Bay of Chiens; Marius (? Seal Bay), New Holland.

13. „ complanata, *Meneghina*
= Discosparsa, *id.*, *Heller*
= (?) D. radiata, *Audouin.*
Geogr. Distrib.: Adriatic.

14. „ annularis, *Heller* = (?) L. mediterranea.
Geogr. Distrib.: Adriatic.

15. „ mellevillensis, *D'Orb.*
Geogr. Distrib.: Port Melleville (? Melville).

As *Radiopora* Busk also gives the following:—

16. Lichenopora simplex, *Busk*, pl. xxxiv. fig. 2.
Geogr. Distrib.: Mazatlan.

17. „ cristata, *Busk*, pl. xxxiv. fig. 1.
Geogr. Distrib.: John Adam's Bank; South Atlantic.

Macgillivray describes as follows new species of Discoporella from Port Phillip Heads:—

18. Lichenopora reticulata, *Macgil.* Descriptions of new or little known Polyzoa, 'Roy. Soc. of Victoria,' Dec. 1883, part vi. pl. i. fig. 1.
19. „ pristis, *Macgil.*, *op. cit.* pl. i. fig. 3.
20. „ echinata, *Macgil.*, *op. cit.* pl. i. fig. 4.

The position of the following is doubtful:—

Tennysonia, *Busk*; stellata, *Busk* ('Cyclostomata,' pl. xxxi. fig. 6).

Genus 9. Domopora, *D'Orb.*

For synonyms, &c., see *Hincks*, 'Brit. Mar. Polyzoa'; *Busk*, Cyclostomata, 'Brit. Mus. Cat.' p. iii.

1. Domopora stellata, *Goldfuss*; *Hincks*, pl. lxiii. figs. 10, 11
= Domopora truncata, *Busk*, *op. cit.* pl. xxxi. figs. 1, 2, not Millepora truncata, *Jameson.*
Mr. Hincks gives nine synonyms, Mr. Busk seven synonyms of this species, besides a number of references by both authors.
Localities: Zetland, deep water; Outer Haaf, in 70 to 170 fathoms.
Geogr. Distrib.: Norway (Rasch); Norway from Bergen to Bejan, 40–60 fathoms (*Sars*).

2. Domopora truncata, *Jameson; Hincks*, pl. lxiii. figs. 5–9
= Millepora, *id.*, *Jameson*; not D. truncata, *Busk*.
Locality: Shetland.

As *Defrancia* Busk adds the following:—

3. Domopora lucernaria, *Sars* (*Busk*, pl. xxxiii. fig. 3).
Geogr. Distrib.: Coasts of Norway and Finmark; Spitzbergen; Umenak, Greenland, 250 fathoms; Julian Hafen, 130 fathoms.

Family V. **Frondiporidæ**, *Smitt*.

(See *Busk*, 'Cyclostomata,' p. 37.)

This family is not noticed by Mr. Hincks in his 'British Marine Polyzoa,' but Mr. Busk describes several species, in his 'Cyclostomata,' under two genera:—

1. Genus Fasciculipora, *D'Orb.*
2. „ Frondipora, *Imperato*.

Genus 10. Fasciculipora, *D'Orb.*

= Fangella, *Hagenow; Busk*, 'Crag Polyzoa,' p. 118.

1. Fasciculipora digitata, *Busk*, pl. xxxiii. fig. 1.
Geogr. Distrib.: Cape Capricorn, Australia.
2. „ ramosa, *D'Orb.; Busk*, pl. xxxiii. fig. 2.
(?) Frondipora ramosa, *Hagenow*.
(?) Fangella prolifera, *Hagenow*.
Geogr. Distrib.: South Patagonia, 48 fathoms (*Darwin, D'Orb.*)
3. „ bellis, *Macgil.*, Description of new or little known Polyzoa, 'Roy. Soc. Victoria,' Dec. 1883, No. vi. pl. i. fig. 2.
4. „ fruticosa, *Macgil.*, *op. cit.* pl. i. fig. 6. *Locality*: Port Phillip Heads, Victoria.

Genus 11. Frondipora, *Imperato*.

1. Frondipora reticulata, *Blainv.* (pl. xxi.).
(See Busk for eight synonyms.)
Geogr. Distrib.: Mediterranean, very abundant.
2. „ palmata, *Busk*, pl. xx. figs. 4, 5.
Geogr. Distrib.: Australia. (?)

Species noticed by other authors:—

3. Frondipora verrucosa, *Lamx.; Busk*, p. 39
= Krusensterna *id.*, *Lamx.*
= Frondipora reticulata, *var.* β, *Smitt*.
Geogr. Distrib.: Kamtschatka, Spitzbergen.
4. „ Marsigli, *Blainv.; Busk*, p. 39.
(A very doubtful species.)

Genus Heteropora, *Blainv.*

'Zoarium erect, cylindrical, undivided or branched; surface even, furnished with openings of two kinds—the larger representing the *orifices*

of the cells, and the smaller the *ostioles* or the interstitial canals or tubes.' —*Busk*, 'Crag Polyzoa,' p. 120.

1. Heteropora pelliculata, *Waters*, 'Journ. Roy. Mic. Soc.,' June 1879, p. 391, pl. xv. figs. 1–4, 7. *Locality*: Gulf of Tartary; Isle of Sanghalien; Japan.
2. „ cervicornis, *D'Orb.* = Plethopora *id.* (*op. cit.* p. 392, pl. xv. figs. 9–11). *Locality*: Adelaide.
   Macgillivray describes the same species under a new generic term, *Densipora*, as D. corrugata, *Macgil.*, 'Roy. Soc. Vic.' *Locality*: Queenscliffe; Portland; Warrnambool.
3. „ Neo-Zelanica, *Busk*, 'Linn. Soc. Journal,' 1879, vol. xiv. p. 725, pl. xv. fig. 14. *Locality*: New Zealand.

See also Nicholson, 'On the genus Monticulipora,' Edinb. 1881, pp. 63–78, in which will be found a rather full description of the structure of Recent Heteropora, for the purpose of making comparison with Fossil species of the Monticuliporidæ. Prof. Nicholson gives figures of Recent *Heteropora Neo-Zelanica*, Busk.

List of Synonyms, &c. compiled from Mr. Hincks' 'British Marine Polyzoa' (Index, 1880).—*Cheilostomata.*

Names in the right-hand column adopted by Mr. Hincks' 'British Marine Polyzoa' and also in this Report.

Acamarchis, *Lamk.*, 1816	= Bugula, *Oken*, p. 73.[1]
Geoffroyi, *Aud.*	= Scrupocellaria reptans, p. 73.
Ætea Americana, *D'Orb.*	= Æ. anguina? *Hincks*, p. 3.
sica, *Norman*	= Æ. recta, *Hincks*, p. 6.
Æteopsis elongata, *Boeck*	= Æ. truncata? *Landsb.*, p. 8.
Alysidota conferta, *Busk*	= Schizoporella discoidea, *Busk*, p. 265.
Amphiblestrum, *Gray*	= Membranipora, *Hincks*, p. 128.
Anarthropora, *Smitt*	= Lepralia, sp. *Busk*, p. 232.
minuscula, *Smitt*	= Anarthropora monodon, p. 233.
Anguinaria, *Lamx.*	= Ætea, *Lamx. & Hks.*, p. 2.
Annulipora, *Gray*	= Membranipora, p. 128.
Avicella, sp. *Van Ben.*	= Bugula, *Oken*, p. 73.
Avicularia, sp. *T. V. Thomps.*	„ „ p. 73.
Berenicea (pt.), *Flem.*	= Membraniporella, p. 199.
Bicellaria unispinosa, *Sars*	= B. Alderi, *Busk*, p. 70.
Bidiastopora (pt.), *D'Orb.*	= Porina (*pars*) *Hincks*, p. 227.
Biflustra, *D'Orb.*	= Membranipora, *Hincks*.
Lacroixii, *Aud.*	= Membranipora, *id.*, p. 130.
Bugula fastigiata, *Alder*	= B. purpurotincta, p. 89.
Bugula nerituna, *var. Gray*	= Cellularia Peachii, *Busk*, p. 34.
Bugularia (sp.), *Gray*	= Bugula, *Oken*, p. 73.
Callopora (sp.), *Gray*	= Membranipora, p. 128.
Canda (sp.), *Busk*	= Scrupocellaria, pp. 43–57. = Caberea, *Lamx.*

GEOGRAPHICAL AND BATHYMETRICAL DISTRIBUTION OF MARINE POLYZOA.

Part I.

The Distribution of Cheilostomatous and Cyclostomatous Polyzoa in the Arctic and Atlantic Seas.

In the following lists I have compiled from various sources the range and distribution of species around a given centre, if I may be allowed to call it such. For this purpose I have taken the whole of the species and varieties described by Mr. Hincks in his 'British Marine Polyzoa,' and have numbered them, 1 to 256, so that by this means an easy reference may be made to any particular form. The localities are indicated by

means of columns and letters, of which the following is a full explanation :—

Col. 1. Shetland, *a* ; Orkney Isles, *b* ; Unst and Hebrides, *c*.
2. East Coast : Scotland, *d* ; Northumberland, *e* ; Durham and Yorkshire, *f*.
3. South-east Coast : Hastings, *h* ; Brighton, *i*.
4. Devon, *j* ; Cornwall, *k* ; West Coast of Ireland, *m''*.
5. West Coast of England, *l* ; EastCoast of Ireland, *m* ; Antrim, *m** ; Isle of Man, *m'*.
6. Guernsey, *n* ; Jersey, *o*. (When every column is filled by an (*) a wide distribution is indicated.)
7. Fossil range : Brit. Glacial, 1 ; Crag, 2 ; Pliocene, 3* ; Miocene, *Reuss*, 3 ; Eocene, 4.

Explanation of the arrangement of the figures in the left-hand column.

This British list is completely arranged in accordance with the classification adopted by Mr. Hincks. It will be seen that the generic and specific arrangement is different from that adopted in the first part of the Report, and to keep up a complete uniformity the following explanation was necessary :—

I. The family names in the British list are those used by Mr. Hincks.
II. So also are the generic ; but against every generic name a number has been placed, and this will be found to correspond with the number and placement of the genus in the classification of Mr. Busk and also the classification adopted by me in the present Report.
III. For obvious reasons I have only numbered in consecutive order the British list. The CYCLOSTOMATA is likewise numbered consecutively, but the columns are differently arranged.

In the other lists the genera are numbered similarly to the British list on the left-hand side, but in the first right-hand column the space is reserved. If the species named is found in any British locality, the number in the British list is given ; if not, the space is left bare. By this simple method, and without disturbing the text and arrangement of different authors, a uniformity of nomenclature throughout the whole of the Report is secured. The blank spaces will sufficiently indicate the species peculiar to any special area.

The same plan is adopted in the list furnished from Mr. Busk's 'Challenger' Report of the bathymetrical distribution of species in the seven regions given by the author. In the last column of this list the geographical distribution is indicated by the use of the following letters, as given by Mr. Busk in the Report, pp. iii to xv of preface :—

A. North Atlantic region ; *B.* South Atlantic region ; *C.* South Indian or Kerguelen region ; *D.* Australian region ; *E.* Philippine or Japanese region ; *F.* North Pacific region ; *G.* South Pacific region.

Complete List of British Marine Polyzoa: Hincks, Norman, Barlee, and Alder. Described by the Rev. Thos. Hincks, 'British Marine Polyzoa,' 1880.

Professor Smitt in the following paper gives a list of localities numbered from 1 to 12.

1. Waideguba = Ajdde-Wuodna in peninsula Ribatschki.
2. Bumanni (l. Bumands.
3. Skarfberget.
4. Subowki.
5. Kola-fjovden (sinu Kola).
6. Semiostrowa.
7. Litza.
8. Kouglaja-juba.
9. Ladigino.
10. Bolschoj-Kletnij.
11. Swiatox-Nos.
12. Lumbowski.

PART III.

Geographical Range of Australian, Pacific, and Indian Polyzoa.

The lists headed A to G compiled from Mr. Busk's monograph ('Challenger' Report on Polyzoa).

Australian Polyzoa. P. H. Macgillivray, M.A., M.R.C.S.

The following list of Macgillivray's Australian species has been compiled for me from various sources—some of which are inaccessible to me—by Miss E. C. Jelly. I have arranged the genera, as far as possible, in accordance with the present catalogue.

I. **CHEILOSTOMATA**, *Busk.*

Fam. IV. **Catenariadæ**, *Busk.*

Gen. 7. Catenicella, *Blainville.*
 gracilenta, *Macgillivray.*
 intermedia ,,
 Wilsoni ,, Port Phillip Heads.
 utriculus ,,
 fusca ,,
 concinna ,, ,, ,,
 pulchella, *Maplestone,* Jour. Micro. Soc. Vict. May, 1880
 = C. concinna, *Macgil.* ? = C. Wilsoni, *Macgil.*
 amphora, *Busk,* M'Coy's, Decade IX. and Brit. Mus. Cat. pt. I.
Alisidota (= ? Catenaria, *Busk, Savigny*).
 ciliata, *Macgil.* ? = C. Wilsoni, *Macgil.*

Fam. V. **Cellulariadæ.**

Menipea, *Lamx.*
 cervicornis, *Macgil.*
Scrupocellaria, *Van Ben.*
 obtecta, *Haswell.* Port Phillip Heads.
Canda, *Lamx.*
 tenuis, *Macgil.*

Fam. VI. **Bicellariadæ.**

Bugula, *Oken.*
 robusta, *Macgil.*
Beania, *Johnston.*
 Beania
 decumbens, *Macgil.*
 Wilsoni, *Macgil.*

Fam. VIII. **Gemellariadæ.**

Family (? *Macgil.*)
Urceolipora, *Macgil.* ? = Ichthyria sp. *Busk.*
 nana, *Macgil.* Port Phillip Heads.
 dentata, *Macgil.*

Maplestonia, *Macgil.* (Family ?)
 cirrata, *Macgil.*
 simplex, *Macgil.*

Fam. XI. **Membraniporidæ.**

Membranipora, *Blainville.*
acifera, *Macgil.*
flagellum, *Macgil.*
papulifera, *Macgil.*
albispina, *Macgil.*
serrata, *Macgil.*
armata, *Macgil.*
bimamillata, *Macgil.*

Membranipora
porcellana, *Macgil.*
Woodsii, *Macgil.*
dispar, *Macgil.*
ciliata, *Macgil.*
Biflustra, *D'Orb.*
perfragilis, *Macgil.* Port Phillip Heads.

Fam. XV. **Salicornariadæ,** *Busk.*

Salicornaria Cuvier (*Cellaria*) *Macgil.*
rigida, *Macgil.* Port Phillip Heads.
australis, *Macgil.*

Fam. XVI. (*a.*) **Porinidæ,** *Hincks.*

Lagenipora, *Hincks.*
tuberculata, *Macgil.*

Fam. XVI (*b.*) **Myriozoidæ,** *Hincks.*

Rhynchopora, *Hincks.*
profunda, *Macgil.*
Porina, *D'Orb.*
magnirostris, *Macgil.* Port Phillip Heads.
gracilis, *Lamk.* „ „

Fam. XVIII. **Reteporidæ,** *Busk.*

Retepora, *Imperato.*
carinata, *Macgil.*
monilifera, *Macgil.*
var. sinuata, *Macgil.* = R. sinuata, *Busk.*
form umbonata, *Macgil.* = R. umbonata, *Busk.*
form munita, *Macgil.* = R. munita, *Busk.*
var. lunata, *Macgil.* = R. lunata, *Busk.*
„ acutirostris, *Macgil.* = R. acutirostris, *Busk*
Petralia, *Macgil.*
undata, *Macgil.* Port Phillip Heads.

Fam. XIX. **Cribrilinidæ.**

Cribrilina, *Gray.*
setirostris, *Macgil.*
monoceros, *Macgil.* Port Phillip Heads.
Membraniporella, *Smitt.*
distans, *Macgil.*

Fam. XX. **Microporellidæ.**

Microporella, *Hincks.*
renipuncta *Macgil.*
Malusii, *Aud.*
var. personata, *Macgil.*

Microporella
 scandens, *Macgil.*
 diadema, *Macgil.*
  var. lunipunctata, *Macgil.*
  „ longispina, *Macgil.*
  „ lata, *Macgil.*
  „ caniculata, *Macgil.*

Fam. XXI. **Escharidæ**

Dictyopora, *Macgil.*
 albida, *Kirchenpauer* (Adeona, *id.*)
  var. avicularis, *Macgil.*
 Wilsoni, *Macgil.* Port Phillip Heads.
Eschara, *Pallas.*
 obliqua, *Macgil.*
 dispar, *Macgil.*
 quadrata, *Macgil.*
 mucronata, *Macgil.*
 elegans, *Macgil.*
Lepralia (*Johnston ?*) *Macgil.*
 anceps „
 Maplestonii „
 vittata „
 elegans „
 lunata „
 trifolium „
 cheilidon „
 caniculata „
 larvalis „
 papillifera „
 Ellerii „
 excavata „
 vitrea „
Lepralia
 megasoma, *Macgillivray.*
 schizostoma „
 botryoides „
 ferox „
 pellucida „
 ceramia „
Porella, *Gray.*
 marsupium, *Macgil.* Port Phillip Heads.
Smittia, *Hincks.*
 oculata, *Macgil.*
 reticulata,
  Var. spathulata, *Macgil.*
Mucronella, *Hincks.*
 munita, *Macgil.*
 lævis, *Macgil.*
 seriatula, *Macgil.*
Schizoporella, *Hincks.*
 lata, *Macgil.*
 insignis, *Macgil.*
 punctigera, *Macgil.*
 magnirostris, *Macgil.*
 Ridleyi, *Macgil.*
 arachnoides, *Macgil.*
 cryptostoma, *Macgil.*

Fam. XXIII. **Celleporidæ.**

? Lekythopora, *Macgil.*
 hystrix, *Macgil.*
Cellepora, *Fabr.*
 munita, *Macgillivray.*
 longirostris „
 platalea „
 serratirostris „
Cellepora
 megasoma, *Macgillivray.*
 rota „
 costata „
 variolosa „
 intermedia „
 exigua „

CYCLOSTOMATA, *Busk.*

Crisidæ, *Milne-Edw.*
Crisia, *Lamk.*
Crisia
 tenuis, *Macgil.*

Tubuliporidæ.

Tubulipora, *Lamk.*
concinna, *Macgil.*
pulchra, *Macgil.*
connata, *Macgil.*
clavata, *Macgil.*
lucida, *Macgil.*
Entalophora, *Lamx.*
regularis, *Macgil.* (Pustulopora).
Idmonea, *Lamx.*
Milneana, *D'Orb.*
australis, *Macgil.*
Diastopora, *Lamx.*
lineata, *Macgil.*
fasciculata, *Macgil.*
bicolor, *Macgil.*
Densipora, *Macgil.*
corrugata, *Macgil.*
Horneridæ, *Smitt.*
Hornera, *Lamx.*
robusta, *Macgil.*
foliacea, *Macgil.*
Lichenoporidæ, *Smitt.*
pristis, *Macgil.*
(= Discoporella).
reticulata, *Macgil.*
(= Discoporella).
echinata, *Macgil.*
(= Discoporella).
? Favosipora, *Macgil.*
rugosa, *Macgil.*
Frondiporidæ, *Smitt.*
Fasciculipora, *D'Orb.*
gracilis, *Macgil.*
bellis, *Macgil.*
fruticosa, *Macgil.*

Polyzoa from Port Phillip Heads, Victoria. Dredged by J. Bracebridge Wilson.[1]

[1] See 'Ann. Mag. Nat. Hist.,' August 1882 and 1884; and 'Descrip. of New Polyzoa,' Macgil., Roy. Soc. Vict., 1880–1883.

This list is far from being complete, but it is compiled from published species (Macgil. and Hincks), and from a list sent with a series of specimens from Port Phillip Heads by Miss E. C. Jelly—some of the dredgings of Mr. Bracebridge Wilson.

ADDENDA.

Cyclostomatous Bryozoa (*Polyzoa*) *from Australia.* A. W. Waters, F.G.S., '*Quart. Jour. Geol. Soc.*,' *Vol. XL.* (*November* 1884).

After the publication of my fifth British Association Report on Fossil Polyzoa, 1884, the above paper was published in the 'Journal of the Geological Society.' I was able, however, to refer to the reading, &c. in a note when correcting the proof sheets of the Report; but as I consider the paper a very important one, I make no apology for giving the following rather full digest, together with remarks on some of the species. Mr. Waters describes thirty-four species of Cyclostomata from Australia, some of which are new, but as he reintroduces for our consideration some of the—now obsolete—names of D'Orbigny and others, it may be well to give the full list of synonyms, &c., furnished by the author.

As a preface to the descriptive matter of this paper, Mr. Waters reviews the whole of the work on Fossil Cyclostomata—very briefly, however—of previous authors; and as some of his remarks bear upon the classification of the Cyclostomata, the student of both Fossil and Recent forms should master the special details of some of the zoœcial characters of the group, especially those parts which refer to the size of the tubes, the ovicells, and also of the pores of the interspaces—cancelli. These details may ultimately help us to understand, more fully than we at present understand, the apparently homologous characters in Palæozoic, and in some few Mesozoic, species of Polyzoa.

1. Crisia unipora, *D'Orb.*, *op. cit.* p. 683, pl. xxx. fig. 1
   = Idmonea unipora, *D'Orb.*, 'Pal. Fr.'
   = Crisina unipora, *D'Orb.*, 'Prodr.' p. 265
   = Crisina elegans, *D'Orb.*, 'Pal. Fr.' pl. (only) 613.

I should be rather inclined to place this species in the genus *Filisparsa*, than in *Crisia*, but as Mr. Waters founds his opinion upon the classifi-

catory position of the species upon the 'closure' of the tube, it would be mere folly to shift it merely because the shape of the zoarium differs from the ordinary run of Crisia.

Locality: Curdie's Creek, Australia.

2. Idmonea atlantica, *Forbes*, *op. cit.* p. 683
   = Idmonea radians, *Van Ben.* (non *Lamk.*)
   = Idmonea inconstans, *Stol.*, 'Bry. Orak. Bay.'
   Localities: Orakei Bay (*Stol.*); Curdie's Creek; Mount Gambier; Bairnsdale.
3. „ Milneana, *D'Orb.*, *op. cit.* p. 648.
   Id., 'Voy. dans l'Amér. Mérid.' vol. v. *D'Orb.*
   = Idmonea giebeli, *Stol.* (Orak. Bay)
   = Idmonea giebeliana, *Stol.* (Orak. Bay)
   = Idmonea notomale, *Busk*, 'Cat. Mar. Pol.'
   Localities: Orakei Bay; Mount Gambier; Curdie's Creek; Bairnsdale.
4. „ radians, *Lamk.*, *op. cit.* p. 684
   = Retepora radians, *Lamk.*, 'Anim. sans vert.,' ii. p. 183
   = Idmonea radians, *Stol.*, 'Bry. d. Orak. Bay.'
   Locality: Mount Gambier.
5. „ Hockstetteriana, *Stol.*, *op. cit.* p. 684, pl. xxx. figs. 12, 13
   = Crisina, *id.*, *Stol.*, 'Foss. Bry. der Orak. Bay.'
   Localities: Orakei Bay; Curdie's Creek.
6. „ bifrons, *Waters*, *op. cit.* p. 685, pl. xxx. figs. 10, 11
   =(?)Tubigera disticha, *D'Orb.*, 'Pal. France'
   =(?)Idmonea disticha, *Hag.*
   Locality: Aldinga.
7. „ aldingensis, *Waters*, *op. cit.* Addendum, p. 696.
   Locality: Aldinga.

'The appearance is much the same as that of *Clavitubigera convexa* (*D'Orb.*, 'Pal. Fr.' pl. 746, figs. 12–15), with the exception that the dorsal surface is concave.'—*A. Waters.*

8. Entalophora verticillata, *Goldf.*, *op. cit.* p. 658
   = Ceriopora verticillata, *Goldf.*, 'Petrifac.'
   = Spiropora antiqua, *D'Orb.*, 'Pal. Fr.'
   = Spiropora neocomiensis, *D'Orb.*, 'Pal. Fr.' p. 708, pl. 784, figs. 1, 2
   = Spiropora verticillata, *Novak.*
   = Spiropora calamus, *Gabb & Horn.*
   =(?)Mitoclema cinctosa, *Ulrich*, 'Amer. Pal. Bry. Jour. Cincin. Soc.' v. p. 159, pl. vi. figs. 7, 7*a*.

Ulrich's *Mitoclema cinctosa* is undoubtedly an Entalophora, but I am very doubtful about its being in any sense identical with any of the other forms cited above by Mr. Waters. The Trenton species are related to the Upper Silurian species of 'Spiropora' described by me in the 'Quart. Jour. Geol. Soc.' p. 55, Feb. 1882; but when describing these forms, I was unable to identify any of the Palæozoic with Jurassic or Cretaceous forms. I have allowed Mr. Waters's suggestion to stand as above, but have simply placed (?) before it.

Other synonyms will be found in Novak and D'Orbigny.

Locality: Mount Gambier.

9. Entalophora raripora, *D'Orb.*, *op. cit.* p. 686
= Pustulopora virgula, *Hag.*
= Entalophora icauensis, *D'Orb*
= „ attenuata, *Stol.*
= „ anomale, *Manzoni*
= „ Haastiana, *Stol.*
= Pustulopora proboscidea, *Busk.*

In justifying the above synonymy Mr. A. W. Waters says: 'I have prepared sections of recent specimens, and also some from the Chalk, Miocene, and Pliocene, without being able to find any difference. The aperture is about 0·16 mm. in diameter.'

Localities: Orak. Bay; Curdie's Creek; Muddy Creek; Mt. Gambier; Aldinga.

10. Entalophora neocomiensis, *D'Orb.*, *op. cit.* p. 686, 'Pal. Fr.' p. 782, pl. 616, figs. 15–18.
? Bidiastopora, *id.*, *D'Orb.* 'Pal. Fr.' p. 800, pl. 784, figs. 9–11
= Cricopora pulchella, *Reuss*
= Spiropora pulchella, *Reuss*
= Pustulopora pulchella, *Manzoni*
= Bidiastopora Toetoeana, *Stol.*

Localities: Orakei Bay; Curdie's Creek; Mt. Gambier; Muddy Creek.

11. Filisparsa orakeinsis, *Stol.*, *op. cit.* p. 687.
Stoliczka, 'Foss. Bry. der Orakei Bay,' pl. xviii. figs. 1, 2.

Localities: Orakei Bay; Curdie's Creek; Mt. Gambier.

Mr. Waters, I think, is quite justified in restoring this genus for certain fossil species. Dr. Jullien (Dragages d. Trav. Bryozoaises, 'Bull. Soc. Zool. de France,' tome vii. 1882, p. 500) 'proposes to make a new genus, *Tervia*, for *Filisparsa*, D'Orb.; but I do not see what reason there can be for this change of name' (*A. W. W.*).

12. Hornera frondiculata, *Lamx.*, *op. cit.* p. 687

Fossil Cheilostomatous Bryozoa from Aldinga and the river Murray cliffs, South Australia. A. W. WATERS, F.G.S., '*Proceedings of the Geol. Soc.*' No. 467, 1885, p. 57, and 'Quart. Journ. Geol. Soc.' Aug. 1885.

I had already placed in the hands of the printer a digest of the above, compiled from Mr. Waters's paper on the Australian 'Cyclostomata,' &c. and from the 'Abstracts,' &c. of the Geological Society. Mr. Waters's full paper, however, came into my hands while the proofs of the present report were being corrected, and I prefer to give the fuller digest rather than the brief abstract prepared.

The paper is one of the most important issued by the author, and its value as a critical production cannot be lightly estimated. In the body of my report I have stated my views with regard to the details of Mr. Busk's monograph on the 'Challenger' dredgings, and Mr. Waters criticises rather freely the work in question. So far as structural features, in certain species, are concerned, either author is capable of taking care of the opinions expressed, and it is to be hoped that the moot-points raised both by Mr. Busk and by Mr. Waters will be duly considered by specialists before venturing to give undue preference to any classification founded upon mere habit. With regard to the plan adopted in the present report I may be permitted to offer a few remarks, with the new evidence of Mr. Waters before me.

After the issue of Mr. Busk's monograph two courses were open to me—either to adopt his classification, and ignore that of Mr. Hincks, or to adopt that of Mr. Hincks and ignore that of Mr. Busk. In either case I should have had to rearrange the whole of the species differently placed to the plan which I might choose to adopt, thus taking upon myself a responsibility that I had no care to face. The course I have adopted is a medium one, and I do not think that by it I shall raise any undue opposition to the plan of the report. My desire has been, in the compilation of these six reports, to lay before the students of Fossil and Recent Polyzoa as full a digest as possible of work done, altogether irrespective of the mode or plan of the different workers. This free-hand dealing with all manner of investigations has been misunderstood by some few critics, but I do not regret that my labours have been so differently regarded. From Mr. Busk, Mr. Hincks, and from Mr. Waters, I do not fear their adverse but friendly suggestions, for all three know too well the difficulties to be encountered in a work like the present one.

The collection described furnishes 73 species, of which 46 are known living, and 8 are new. This brings up the number of described fossil Australian Polyzoa to 220, of which just about half have been found living. The new species and varieties in this list are marked with an (*) after Mr. Waters's name.

Fossil Tertiary Polyzoa of the higher Zones, and Note on the Scarcity of Eocene Polyzoa. By ALFRED BELL, Esq.

In my fifth Report on Fossil Polyzoa (1884) I presented a list of species from the Crag and also from the Palæolithic beds of Great Britain. This I did from all the sources that were available to me at the time. Since the publication of my Report in the volumes of the British Association Mr. Alfred Bell, the well-known authority on these upper beds, has compiled for me a complete and corrected list of the distribution of the Polyzoa from every source available to him.

Notes on the Higher Tertiary Zones.

1. Coralline Crag.

2. Lower Red Crag, or Fusus contrarius Zone.—I.e. the oldest part of the Red Crag (Walton-Naze) in which the Fauna is almost entirely free from the mammalia (cetacean and terrestrial), London Clay, and older rocks and fossils and other miscellaneous remains.

3. Middle Red Crag, or F. antiquus Zone.—The district between the rivers Deben and Orwell; with the above remains a large proportion of extinct shells and few living mammalia.

4. Upper Red Crag, including Norwich Crag, free from the above remains. Shells nearly all recent forms; Mammalia, Quaternary, or still living species.

5. Pre-glacial.—I.e. Wexford, Chillesford, Weybourn Sands, Bure Valley, and all beds between the last and the succeeding Arctic or First Glacial period.

6. Arctic.—Bridlington, Tangy Glen, Erie, Errol, Fife, and other beds in and underlying the Boulder Clay.

7. Palæolithic.—Garvel Park, Dalmuir, and most of the Scottish beds in the north; the Lancashire drifts, Selsey, Portrush, and the Cambridgeshire districts; Fauna indicating warmer conditions than now prevail.

(Second or later glaciation, possibly, than some of the Scotch beds above.)

8. Neolithic. — Belfast and Estuarine Clays generally, not very fossiliferous.

'Miocene Polyzoa.'

Miocene Polyzoa, so abundant in Continental beds, are, I believe, unknown in the British.

'Eocene Polyzoa.'

Note on the Scarcity of Eocene Polyzoa.

Considering the richness of other sections of organic life in the Eocene, the great poverty of the Molluscoida (Brachæopoda and Polyzoa) is very remarkable, and this poverty does not arise from an oversight on the part of collectors, or for want of looking for. Some thousands of specimens having passed through the hands of one or other of us, it is possible to speak with some amount of certainty upon this head. Of the few species listed, Memb. Lacroixii, Flustra crassa, and Lunulites urceolatus are the commonest, but are by no means abundant; and the first two have a wide range in Eocene time. Neither do they occur in any quantity in the Continental Eocene fauna, as an examination of some thousands of shells from the Paris basin will expose an equal sparseness.

The cause of this absence is difficult to explain, as far as the free growing Cyclostomata are concerned, unless that the soil, or food, or other conditions of life, was not favourable for their development. For the adnate Cheilostomata, the want of such shells or adherent surfaces proper for their habitat may be sufficient cause.

Reasoning from the rich Crag fauna, it would appear that Polyzoa require certain genera of mollusca, and only certain species of these are selected, dead shells and shell banks among the bivalves especially being in demand, the *Pecten opercularis* and *Geradi*, *Pectunculus*, *Cytherea rudis*, *Pholas*, *Solen*, *Tellinas crassa* and *obliqua*, *Fusus antiquus*, *Nassa* and *Columbella*. Other genera are less so, and of these *Fissurella*, *Capulus*, *Buccinanops* (?), *Purpura*, *Tetragona*, *Ostrea*, and *Cardium* are the chief. Terebratulæ are good hunting grounds in the Coralline, but not in the Red Crag. With the exception of *Solen*, *Pectunculus*, and others, these genera are rare, or at least numerically so individually in the Eocenes, and of these it may be said that very few examples are known in a worn or 'dead' condition. Drifted shell banks are not common. Most of the species are in their native haunts, or where they have been removed, the genera, such as *Cyprina*, are not those selected for attachment.

The conditions of life again are not favourable; the Eocene of England consisting of either sharp sand or muddy clay; estuarine or freshwater beds.

Sharp sand is also unfavourable for preservation, as in the case of the Oldhaven sand at Bromley, where the *Pectunculi* are in millions, with the surfaces nearly all decorticated, and in the London clay. Casts of the shells are alone preserved (save a few portions of the test) in a pyritised condition.

There is only one other reason I can suggest for their absence, *i.e.* that the Molluscoida had reached their apogee in the cretaceous period, and only few genera and individuals represented this class of organism, till other times and conditions more favourable to their existence came in, in other words, that they were non-existent.

Mr. Bell has certainly given very fair explanations of some of the causes which prevented the full development of a Polyzoan fauna, and I am glad to be able to give currency to his views. In my fifth British Association Report I remarked that we might owe the scarcity to want of research. This, however, seems not to be the case. The following is the only list that I can supply:—

Eocene Polyzoa.

Note on Professor G. SEGUENZA'S *List of Tertiary Polyzoa from Reggio (Calabria).* Rev. THOMAS HINCKS, *Annals, 'Mag. Nat. Hist.'* April 1884. (*Le formazioni terziarie, &c.* 1879 *and* 1880.)

1. Lepralia elegantissima, *Seguenza*, p. 83, pl. viii. fig. 11
= Cribrilina radiata, *Moll.* form innominata, *Couch.*
2. „ radiato-faveolata, *Seg.*, p. 129, pl. xii. fig. 20
= Microporella violacea, *Johnst.*
3. Cumulipora porosa, *Seg.*, p. 130, pl. xii. fig. 21
= Smittia trispinosa, *Johnst.*
4. Lepralia radiato-porosa, *Seg.*, p. 129, pl. xii. fig. 19
= or *var.* Schizoporella unicornis, *Johnst.*, including L. ansata, *Johnst.*
5. „ exima, *Seg.*, p. 203, pl. xiv. fig. 23, *Johnst.*
= Membraniporella nitida, *Johnst.*
6. „ calabra, *Seg.*, p. 201, pl. xv. fig. 6
= Microporella ciliata, *Pall.*
7. „ mitrata, *Seg.*, p. 203, pl. xv. fig. 8
= Cribrilina radiata, *Moll.*
8. „ coronata, *Seg.*, p. 295, pl. xvii. fig. 6.
A variety of Microporella Malusii, *Aud.* Chiefly remarkable for the curiously furrowed surface of the oœcium.
9. „ thiara, *Seg.*, p. 370, pl. xvii. fig. 57
= Cribrilina punctata.
10. Salicornaria mammillata, *Seg.*, p. 294, pl. xvii. fig. 5.
Probably a species of Myriozoum.

Mr. Hincks remarks (p. 267, *op. cit.*) that 'Professor Seguenza's work is of such sterling character, and will deservedly have so much weight with the student, that it seems peculiarly desirable to prevent these spurious species, if possible, from sheltering themselves under his authority.'

1878. Notes on the genus Retepora, with descriptions of new Species. 'Annals and Mag. Nat. History,' 5th ser. vol. i. 2 plates, pp. 353–365.

In this paper the author describes nine species of *Retepora*, five of which are new—*R. Couchii*, *R. prœtenuis*, *R. plana*, *R. tessellata*, and *R. robusta*—and he gives very full details of the other four. Mr. Hincks also gives a brief account of the previously described species of authors. As usual, the new and some of the known species are illustrated as well as described.

1879. On the Classification of the British Polyzoa. 'Ann. Mag. Nat. Hist.' 5th ser. vol. ii. pp. 153–164.

This is a paper on 'certain portions of the Classification adopted in the History of the British Marine Polyzoa.'

1880. 'A History of the British Marine Polyzoa,' 2 vols. Vol. i., text; vol. ii., plates.

In this work Mr. Hincks describes and figures every known species of British Ctenostomata, Cheilostomata, and Cyclostomata. The work should be consulted by every student who desires to make known to science the species found in many of the still partially known British localities.

1880. Note on a supposed Pterobranchiate Polyzoon from Canada. 'Ann. Mag. Nat. Hist.' 5th ser. vol. vi. p. 239.

1880. Contributions towards a General History of Marine Polyzoa. 'Ann. Mag. Nat. Hist.' 5th ser. vol. v. pp. 69–91, plates ix., x., xi.

In this paper Mr. Hincks describes, Part I. Madeira species which belonged to the cabinet of J. Y. Johnson, Esq., of Madeira. Some of the collection had been previously described by Mr. G. Busk. Mr. Hincks, however, makes many additions to Mr. Busk's list. Part II. Foreign Membraniporidæ.

1880. On New Hydroida and Polyzoa from Barrent's Sea. 'Ann. Mag. Nat. Hist.' 5th ser. vol. v. pp. 277–286, plate xv.

A full list of the Polyzoa obtained by Mr. W. J. A. Grant in the Arctic Sea was given in the same volume of the 'Annals.' Mr. Hincks's paper contains a detailed description of the new forms which occur in the collection. Among the Ctenostomata one new genus—*Barrentsia*, Hincks—is described, and a new species—*B. bulbosa*, Hincks.

1880. Foreign Membraniporidæ. 'Ann. Mag. Nat. Hist.' Nov., 5th ser. vol. vi. pp. 376–381, plates xvi. and xvii.

Besides the Membranipora, Mr. Hincks describes *Steganoporella* and species referable to the genus. Pt. II. Foreign Cheilostomata, Miscellaneous.

1881. Contributions towards a General History of Marine Polyzoa. I. Foreign Membraniporina; II. Foreign Cheilostomata. 'Ann. Mag. Nat. Hist.' 5th ser. vol. vii. plates viii., ix., x. pp. 147–161.

In this paper Mr. Hincks established the family *Epicaulidiidæ* and the genus *Epicaulidium* for a species which was afterwards withdrawn; and a new genus of the *Escharidæ*—*Aspidostoma*, Hincks.

1881. On a Collection of Polyzoa from Bass's Straits, presented by Capt. W. H. Cawne-Warren to the Liverpool Free Museum.

A paper read before the Lit. and Phil. Soc., Liverpool, April 18, 1881, pp. 1–22.

1881. Polyzoa of Bass's Straits (Contributions), 'Ann. Mag. Nat. Hist.' July, vol. viii. plates i., ii., iii.

The collection of Capt. Warren contained ninety-two species, twenty-two of which are European.

1881. Contributions, &c. 'Ann. Mag. Nat. Hist.' 5th ser. vol. viii. plates iv. and v. pp. 122–136.

In this paper Mr. Hincks continues his descriptions of species from Bass's Straits, and then afterwards his descriptions of Foreign Membraniporina (third series) and Foreign Cheilostomata. Several species of *Diachoris* are described, and the genus and species of Epicaulidium are withdrawn.

1882. On certain remarkable modifications of the Avicularium in a species of Polyzoon, and on the relation of the Vibraculum to the Avicularium. 'Ann. Mag. Nat. Hist.' 5th ser. vol. ix. pp. 20-25. Several woodcuts, no plate.

„ Contributions, &c. Foreign Cheilostomata (miscellaneous). 'Ann Mag. Nat. Hist.' 5th ser. vol. ix. plate v. pp. 79–90.

Several new species are described from different localities, most of which are from the cabinet of Miss E. C. Jelly.

1882. Contributions, &c. 'Ann. Mag. Nat. Hist.' August. 5th ser. vol. x. p. 160, plates vii. and viii.

In this paper Mr. Hincks describes (family Eucratiidæ) a new genus, Rhabdozoum, for the reception of a species, *R. Wilsoni*, from Port Phillip Heads. In the family Membraniporidæ a new genus, *Euthyris*, and a new species, *E. obtecta*, from Australia. Besides these other species of Foreign Polyzoa are described.

1882. Preliminary notice of new species of Polyzoa from Queen Charlotte Islands. In the paper 21 new species are described but not illustrated. 'Ann. Mag. Nat. Hist.' Sept., pp. 248–256.

„ Polyzoa of the Queen Charlotte Islands. Part I. December. 'Ann Mag. Nat. Hist.' plates xix. and xx. 5th ser. vol. x.

1883. Contributions, &c. Foreign Cheilostomata from Australia and New Zealand. Describes two new genera, *Stiparia*, Goldstein, and *Stolonella*, Hincks. 'Ann. Mag. Nat. Hist.' p. 193, plates vi. and vii. March.

„ Polyzoa of Queen Charlotte Islands. Part II. June. 'Ann. Mag. Nat. Hist' 5th ser. vol. xi. plates xvii. and xviii.

1884. Continuation of above. Part III. January. 'Ann. Mag. Nat. Hist.' 5th ser. vol. xiii. plates iii. and iv.

„ Completion of Report on Polyzoa of Queen Charlotte Islands. 'Ann. Mag. Nat. Hist.' 5th ser. vol. xiii. plate ix. Cyclostomata, Ctenostomata, and Addenda.

„ Report on the Polyzoa of the Queen Charlotte Islands. Ottawa: MacLean, &c. Published in connection with other works on the Geological and Natural History Survey of Canada, pp. 1–44, and the whole of the plates.

The above work is a reprint of the four papers and seven plates originally published in the 'Annals,' December 1882, June 1883, January and March 1884. In the Report ninety-six species are recorded, thirty-six of which had not been previously described.

1884. Note on Professor G. Seguenza's List of Tertiary Polyzoa from Reggio (Calabria). 'Ann. Mag. Nat. Hist.' April, 5th ser. vol. xiii. pp. 265–267.

„ Contributions, &c. XII. Polyzoa from India (coast of Burmah). XIII. Polyzoa from Victoria and Western Australia. 'Ann. Mag. Nat. Hist.' 5th ser. vol. xiii. pp. 356–369, plates xiii. and xiv.

The paper contains descriptions of Cheilostomata and Ctenostomata.

1884. Contributions, &c. XIII. Polyzoa of Victoria, continued. 'Ann. Mag. Nat. Hist.' October 1884, pp. 276–285, plate ix.

In this paper Mr. Hincks describes a new family of Cheilostomata, Cyclicoporidæ, and a new genus, *Cyclipora*, for the reception of the species, C. prælonga, Hincks.

1885. Contributions, &c. Polyzoa from New Zealand and Australia. 'Ann. Mag. Nat. Hist.' March 1885, vol. xv. pp. 244–257, plates vii.–ix.

WATERS, A. W., F.G.S.

1878. On Bryozoa. Manchester Lit. and Phil. Soc., Microsc. and Nat. Hist. Sect., vol. xvii. pp. 125–138.

In this paper Mr. Waters reviews as a popular outline of the class Polyzoa the zoological position of the various groups, detailing at some length his reasons for adopting the term *Bryozoa* instead of *Polyzoa.*

1878. On the Use of the Opercula in the Determination of the Cheilostomatous Bryozoa. 'Proc. Manchester Lit. and Phil. Soc.' vol. xviii.
1879. On the Bryozoa (Polyzoa) of the Bay of Naples. 'Ann. Mag. Nat. Hist.' 5th ser., vol. iii. pp. 28–43, plates viii. and xi. Part I. reviews the literature of the subject, and describes 32 species of *Lepralia* (old nomenclature) and one *Eschara.*
1879. Bryozoa of the Bay of Naples. Part. II. Cheilostomata, continued. *Op. cit.* February, pp. 114–126, plates xii., xv.

Describes twenty-eight species of various genera.

1879. Bry. Bay. Nap, Pt. III. *Op. cit.* pp. 192–202.

Describes thirteen species of *Cellepora*, two of *Retepora* and *Myrozoum truncatum*, Pallas.

1879. Bry. Bay. Nap. Pt. IV. Cyclostomata and Ctenostomata. *Op. cit.* pp. 267–281, plates xxiii., xxiv.

Describes thirty-three species, in all 111 species of Bryozoa, as found in the Bay of Naples. In the whole of these papers Mr. Waters gives a very full synonymous list and references, both fossil and recent, and a very valuable list of localities in which the species are found.

1880. On the terms *Bryozoa* and *Polyzoa*. 'Ann. Mag. Nat. Hist.' January, pp. 1–3.
1879. On the occurrence of recent *Heteropora*. 'Jour. Mic. Soc.' vol. ii. pp. 390–393, pl. xv. Paper read May 1879.

A very important paper giving details of structure of *Heteropora*, both recent and fossil. Describes as new *H. pelliculata*, Waters, and re-describes *H. cervicornis*, D'Orb.

1880. Note on the genus *Heteropora*. 'Ann. Mag. Nat. Hist.' vol. vi. p. 156.
1884. Closure of the Cyclostomatous Bryozoa. 'Linnæan Soc. Jour. Zoology,' vol. xvii. pp. 400–404, pl. 17.

STUART O. RIDLEY.

1881. Account of the zoological collections made during the survey of H.M.S. 'Alert' in the Straits of Magellan and on the coast of Patagonia. Proceedings of the Zoological Society of London, January. In two parts: I. Polyzoa, pp. 44-61, pl. vi.; II. Cœlenterata, pp. 101-107.

In the Polyzoa part, Mr. S. O. Ridley establishes a new genus—*Gigantopora*, Ridley—for the placement of a species described and figured *G. lyricoides*, Ridley; and in his observations he says that *Hippothoa fenestrata*, Smitt, 'Flor. Bryoz.' must also be ranked under the genus.

1881. Polyzoa, Cœlenterata, and Sponges of Franz Josef Land. 'Ann. Mag. Nat. Hist.' June, pp. 442-457, pl. xxi.

Several species of Cheilostomata and three of Cyclostomata are described, amongst the latter young colonies of what Mr. Ridley believes to be *Heteropora pelliculata*, Waters (?). 'This genus,' says the author, 'is already known from New Zealand, Australia, and the Japanese seas, and in the fossil state: its recent distribution is now extended to the Arctic seas,' p. 453.

1882. Notes on Zoophytes and Sponges obtained by Mr. F. Day off the east coast of Scotland. 'Linnæan Soc. Jour. Zoology,' vol. xvii. pp. 105-108.

Contains a brief note on Polyzoa.

I am fully aware that there are several bibliographical papers omitted in the above list. Many of these, however, are particularly of a structural character, and I was in hope that I should have been able to include these, with special remarks upon them, in some future Report. At present my labours are so far complete up to this point only. The structural peculiarities of several polyzoal groups, together with remarks on the Ctenostomata, must remain in abeyance, for the present at least. There are a few papers not recorded above that may be specially referred to. Dr. Jullien's work on 'Recent Species' I was not able to procure or even get a sight of; and equally inaccessible were D'Orbigny's 'Descriptions of South American Polyzoa'; the writings of Krauss, Meneghini, W. Stimpson's 'Invertebrata of Grand Manon,' Verrill's 'Recent Additions to Marine Invertebrata,' or Risso's 'Fauna of the Mediterranean,' &c. Mr. Quelch's labours on the group, however, may be mentioned, though his writings may be few in number. His remarks on *Spiralaria*, Busk—a peculiar polyzoon not as yet classified—and on certain species of *Schizoporella* ('Ann. Mag. Nat. Hist.' 1884), merit attention; so also references to Dr. Jullien's labours in Mr. A. W. Waters's papers on 'Fossil Bryozoa'; and special reference should be made to the article on Polyzoa in the 'Encyclopædia Britannica,' by Dr. Ray Lankester, F.R.S. Another paper by Mr. A. W. Waters, F.G.S., just to hand (November 1885), may be mentioned. This is one on the 'Avicularian Mandibles,' &c. and a very important one withal.—*Journ. Roy. Mic. Soc.* Ser. 2, vol. v. pp. 774-779.

Third Report of the Committee, consisting of Sir J. HOOKER, Dr. GÜNTHER, Mr. HOWARD SAUNDERS, *and* Mr. SCLATER (*Secretary*), *appointed for the purpose of exploring Kilima-njaro and the adjoining Mountains of Equatorial Africa.*

1. IN their last report, presented at Montreal, the Committee stated the arrangements that they had made with Mr. H. H. Johnston for undertaking an expedition to Kilima-njaro, and gave extracts from Mr. Johnston's letters showing the progress of his expedition up to May 1884.

2. Mr. Johnston returned to this country in December last, and gave an account of his expedition to the Royal Geographical Society at their meeting on January 26, 1885,[1] which is published in their Journal.

3. Mr. Johnston there tells us he was much hampered, as regards collecting, by the desertion of two natives whom he had taken out with him from Zanzibar as collectors. The consequence of this was that the collections, although containing many objects of great interest, are not so large as the Committee could have wished.

4. The Committee requested Captain Shelley to prepare a report on the birds collected by Mr. Johnston, and Mr. F. D. Godman on the butterflies of his collection, after which the first sets in both these collections were handed over to the British Museum.

5. All the other zoological collections were likewise handed over to the British Museum, with a request to the Director that reports might be prepared for publication on such portions of them as seemed to be of sufficient interest.

6. The following reports on the zoological collections made by Mr. H. H. Johnston have already been published in the 'Proceedings' of the Zoological Society for this year:—

(1) General Observations on the Fauna of Kilima-njaro. By H. H. Johnston. P.Z.S., 1885, p. 214.

(2) Report on the Mammals obtained and observed by Mr. H. H. Johnston on Mount Kilima-njaro. By Oldfield Thomas, F.Z.S. P.Z.S., 1885, p. 219.

(3) On the Collection of Birds made by Mr. H. H. Johnston in the Kilima-njaro District. By Captain G. E. Shelley, F.Z.S.; with Field-notes by Mr. H. H. Johnston, F.R.G.S. P.Z.S., 1885, p. 222.

(4) On the Insects collected on Kilima-njaro by Mr. H. H. Johnston. By Charles O. Waterhouse. P.Z.S., 1885, p. 230.

(5) Note on a Nematoid Worm (*Gordius verrucosus*) obtained by Mr. H. H. Johnston on Kilima-njaro. By F. Jeffrey Bell, M.A., F.Z.S. P.Z.S., 1885, p. 236.

(6) Description of a New Variety of River-Crab, of the genus *Thelphusa*, from Kilima-njaro. By E. J. Miers, F.L.S., F.Z.S. P.Z.S., 1885, p. 237.

(7) A List of the Lepidoptera collected by Mr. H. H. Johnston during his recent expedition to Kilima-njaro. By F. D. Godman, F.R.S., &c. P.Z.S., 1885, p. 537.

7. The botanical collections were handed over to the Royal Herbarium at Kew, where they have been arranged and named. A set of them has been sent to the British Museum. The report upon them is ready, and will be presented to the Linnæan Society for publication.

[1] See *Journ. Proc. Roy. Geogr. Soc.*, 1885, p. 137.

8. Professor Bonney has kindly undertaken to report on the rock and mineral specimens collected by Mr. Johnston, and his report is presented herewith, and will be read in the Geological Section.

9. Mr. H. H. Johnston has in preparation a volume containing a narrative of his expedition and a summary of the results arrived at, which will shortly be ready for issue.

10. The sum of 25*l.* granted to the Committee at the Montreal meeting has been returned to the Treasurer.

APPENDIX.

Report on the Rocks collected by H. H. Johnston, Esq., from the upper part of the Kilima-njaro massif. By Professor T. G. Bonney, *D.Sc., F.R.S., Pres. G.S.*

The collection consists of forty rock and six mineral specimens—most of them rather small pieces—which in several cases have evidently not been broken from rocks *in situ*, but have been lying about on the ground as loose fragments.

(1) *Stream Valley, Kilima-njaro*, 13,000 feet (16 fragments).—These are rolled pebbles or fragments, more or less waterworn, varying in diameter from about three-quarters of an inch to one and a-half inch. They consist of a black glassy rock, of a very dark grey subvitreous rock, or an extremely compact lava (all obviously not very different from glassy basalts), together with five specimens of more or less scoriaceous rock, the last named being more waterworn than the other. These are a dark compact rock, containing crystals (sometimes quite an inch long) of a glassy felspar in rather tabular crystals, which is probably identical with one to be presently described. Of the former group I have selected three for microscopic examination as being fairly representative of the series.

(*a*) Fragment (somewhat rounded) of black glass of slightly resinous lustre, with faint indications of a fluidal structure. Examined microscopically, it appears as a banded brown glass, varying in colour from a rather pale to a warm brown tint. Both, but especially the latter, are streaked with elongated trichites of dark brown to black colour, and the darkest band is beautifully 'marbled' by darker streaks and filamentous trichites. Scattered about are acicular microliths; some of the smaller and thinner are probably felspar, but certain of the larger show good hexagonal sections, and may be safely identified as apatite. Three or four rounded grains, associated twice with apatite and once with magnetite (?) also occur. They are either olivine or augite—I think the latter; neither cleavage nor external form is sufficiently definite to enable me to speak with certainty. I regard them as the remnants of crystals, of which the external angular portion has been melted away. The rock may be classed with the augite-andesite glasses, and belongs to the more basic side of the group.

(*b*) A similar rock, but with a rather duller lustre. Examined with the microscope under a low power, it seems to be a rather opaque-looking darkened grey glass. With high powers, there appears to be a base of clear glass from which the magnetite has separated in minute granules and 'dusty' patches and a number of very minute belonitic crystals, probably felspar, have formed. There are slight indications of fluidal structure. In the slide is a perfectly round grain of hornblende, a fragment or two of felspar, a few small crystals of apatite (?), and two bits

of scoria, evidently picked up by the molten rock. These resemble an andesite, being full of plagioclase microliths, and one of them contains two larger broken plagioclase crystals.

(*c*) Is a very compact, almost black rock, without vitreous lustre. Examined with the microscope, it is seen to be very similar to the last, except that the separation of the minerals has proceeded a little further; the opacite granules and felspar microliths being slightly larger. There are one or two crystals in the slide of larger size; felspar, broken looking, magnetite and apatite.

(2) *Central Ridge, Kilima-njaro*, 14,000 feet (7 specimens of rock, 1 mineral).—Of the rock specimens (*a*) two are rather rounded; a very compact, dark grey, almost black rock. (*b*) Three flattish, rather scoriaceous fragments, two of them having a very marked platy structure, so that at first sight they might be taken for stratified. (*c*) Two are soft fragments of a dark brown compact rock (seemingly rather decomposed), containing crystals, more than half an inch in diameter, of a rather glassy felspar.

(*a*) I have examined slices from each of these. One of these differs very little from that last described, 1 (*c*), except that there seems to be a general tendency to form minute spheroids (without a radial crystalline structure), coated externally with a film of iron oxide. The other specimen belongs, no doubt, to a similar rock, as its glassy base is now crowded with elongated microliths of a plagioclastic felspar and granules of magnetite. The slide contains two crystals of brown hornblende, one or two crystals of nearly colourless augite, and a few minute patches, probably of brown glass. (*b*) I have not examined these microscopically, as they appear to me only more scoriaceous forms of (*a*). (*c*) One of these has been examined. The ground mass has a general resemblance to that of the first specimen in (*a*), but appears rather more decomposed. In this occur a few grains of a nearly colourless mineral, some certainly augite, though olivine may also be present. The former appears once or twice to have been more or less replaced by magnetite, which mineral also occurs in independent crystals, and there is a little apatite. The large felspar crystals, two of which are partly included in the slide, are worn and rounded at the edges and have several inclusions of the ground mass. They present a general resemblance to sanidine.

The separate crystal of a mineral has evidently been detached from a similar rock; it is about four-thirds of an inch long and rather more than half an inch wide. It bears a general resemblance to sanidine, but the form is a very peculiar one for this mineral to assume. The faces of ∞P are well developed, OP rather small, together with another face in the vertical zone; $\infty \breve{P} \infty$ small. Distrusting my own opinion, I referred the crystal to my friend Mr. T. Davies, of the Mineral Department of the British Museum. He at once intimated that the form was very unusual, and, after consultation with the other officers of the department, wrote to me that the crystal was a variety of orthoclase. This, with some others mentioned below, will, I hope, be described more at length by Mr. Miers at the next meeting of the Mineralogical Society.

Stones of Kimawenzi (3 specimens).—These specimens appear to be of a very similar rock, and are all more or less decomposed. They are practically identical with 2 (*c*), so I have not had a slide cut. They also contain good-sized crystals of the same peculiar felspar.

Stone, base of peak, Kimawenzi, 14,700 feet.—Slab about $6\frac{1}{2}'' \times 4\frac{1}{2}'' \times \frac{1}{2}''$

of a compact, very dark grey rock, weathered externally to a paler colour. In it are scattered a fair number of crystals of black hornblende (?) up to about $\frac{1}{4}''$ in longest diameter. Except for a mere external film, the rock is in good condition.

Under the microscope a clear glassy base is seen thickly crowded with microliths of plagioclase felspar, granules and small crystals of augite, and granules and grains of magnetite. Four of the larger crystals of hornblende are present in the slide; these have a worn, corroded look externally, and are black bordered; they are a rich olive-brown colour. There are also two crystals of light-coloured augite of about the same general size as the hornblende—one with fairly well defined angles, not black bordered; the other less perfect, with some appearance of a black border; also a smaller one which seems to include at one side a fragment of hornblende. The rock is an augite-andesite, containing some hornblende of anterior consolidation.

Rocks from base of Kimawenzi, 15,000 feet (2 specimens).—Of these rocks one is a dark, decomposed, compact rock like 2 (*c*); the other contains the same felspar, but is paler in colour. I have not had these cut for the microscope.

Rocks from base of Kibo, 14,000 feet (8 specimens of rocks, 4 specimens of minerals.—The rocks are externally a good deal decomposed, and closely resemble those from the base of Kimawenzi and from the central ridge 2 (*c*). I have had a slice prepared from the one which seemed in best preservation. The base is a dark brown glass of rather decomposed aspect, in which are scattered minute felspar microliths as already described. There are several small vesicles visible in the slide, together with minute circular spots of an isotropic mineral, probably yet smaller cavities filled up by some secondary products. Parts of two of the peculiar felspar crystals already mentioned occur in the slide. Externally they have a rather rounded aspect, internally there are many inclosures of the base. They have a general resemblance to sanidine, but one shows rather distinctly a peculiar cross-hatched structure not unlike that of microcline. The mineral specimens are all pieces of separate crystals of this felspar, which have probably been about the same size as that described from the central ridge. They are, I am informed, like it, a variety of orthoclase, and some exhibit twinning, the composition face being the orthopinakoid.

Three specimens without any label. Bad specimens of a rock very similar to the last described.

As will be seen from the above notes, the collection of rocks from these interesting localities indicates (1) that the highest peaks of the Kilima-njaro *massif* consist of rather basic rocks; (2) that these rocks are all of them more or less vitreous, a glassy base having been discerned in all that have been examined; (3) that these rocks fall into two groups; (*a*) dark, glassy, or scoriaceous rocks, never showing much more than a microporphyritic structure—varieties of augite-andesite, more or less glassy; (*b*) brownish to greyish rather slaggy rocks, containing the above-described large crystals of a glassy variety of orthoclase. The base is evidently not rich in silica, and does not, I suspect, materially differ from that of the other group, so that I should regard these as intermediate between the normal augite-andesites and the normal sanidine-trachytes, and name them provisionally orthoclase-bearing augite-andesites. Mr. Johnston's collection is, I think, sufficiently ex-

tensive and numerous to justify us in assuming that the upper part of the Kilima-njaro *massif* chiefly consists of one or the other of these two allied groups of rocks; the only point of special interest in them being the abundant occurrence of this peculiar variety of orthoclase.

A fragment of a crystal, found in 'Stream Valley' at about 8,000 feet on Kilima-njaro, 'much coveted by the natives for ornaments, and said to be found only after heavy rains,' is simply rock-crystal (quartz). This mineral appears to indicate the presence of more siliceous rocks than the above; not improbably of either granite, gneiss, or some kind of schist.

P.S.—While the above description was in the press, another specimen reached me, which had previously been mislaid. It is labelled 'Found in a stream valley on Kilima-njaro,' and is a fragment, smoothed on all sides but one, of a black lava, in most parts very vesicular, the longest diameter being about $3\frac{1}{2}$ inches. It is evidently either a rather basic augite-andesite glass or a basalt glass; probably the former, like other specimens described above.

Report of the Committee, consisting of Mr. John Cordeaux (*Secretary*), Professor A. Newton, Mr. J. A. Harvie-Brown, Mr. William Eagle Clarke, Mr. R. M. Barrington, *and* Mr. A. G. More, *appointed for the purpose of obtaining (with the consent of the Master and Brethren of the Trinity House and the Commissioners of Northern and Irish Lights) observations on the Migration of Birds at Lighthouses and Lightvessels, and of reporting on the same.*

The General Report[1] of the Committee, of which this is an abstract, forms a thick pamphlet of 186 pages, and comprises observations taken at lighthouses and lightvessels, as well as at several land stations, on the coasts of Great Britain and Ireland, and the outlying islands; also from Heligoland, two stations in the Baltic, the Faroe Islands, and Iceland. Independent notes and observations have also been received from several ocean steamships in the Atlantic and Polar seas.

Altogether 193 stations have been supplied with printed schedules for registering observations, and returns have been sent in from 118. The number of schedules returned from each station varies considerably, and is in some degree dependent on the interest taken in the subject by the observers, but chiefly perhaps on the position of the station being favourably or otherwise situated for observation.

The usual number of schedules returned from a station is one or two; in many cases this is greatly exceeded. The Pentland Skerries, Isle of May, and Inner Farn Island lighthouses, have sent in fourteen, twelve, and nine respectively. The total number of schedules returned is greatly in excess of previous years, and the labour of arranging, tabulating, and reporting thereon has been considerably increased.

The Committee have this year added a new feature to their report in an outline map of the British Isles, showing the stations, marked in red. This map has been prepared by Messrs. McFarlane and Erskine, of Edin-

[1] *Report on the Migration of Birds in the Spring and Autumn of* 1884. West, Newman, & Co., 54 Hatton Garden, London, E.C.

burgh. It will prove a useful and valuable addition to the report, and a great assistance to readers and observers.

The report shows that on the east coast of England a great movement was carried on for six months in the autumn and winter of 1884–5 The schedules returned indicate that no one place had special preference, and that the inflow of migrants was equally distributed over the entire coast line.

The southerly movement of migrants was well established in July, and from this time to the end of the third week in January 1885 there was a steady flow, with slight intermissions, of birds either passing along the coast to the south or moving directly inland, the vast majority coming from the east across the North Sea, and moving westward or in westerly directions. Occasionally there have been heavy rushes or persistent bird waves, continuous for days and even weeks.

The periods of migration occupied by different species vary greatly, from four weeks to as many months; no general rule can be laid down in this respect.

There was an immense and continuous rush on to the coast from the middle of October (15th) to the end of the month, migrants arriving continuously night and day. This rush was continued at some of the stations with but slight intermissions to the middle of November.

On the east coast of Scotland, whilst desultory movements continued during September and October, the heaviest rushes are recorded in the middle of November.

The last fortnight in October is the average annual period of what may be called the 'great rush' of immigrants on to the east coast of England.

In previous reports attention has been drawn to the fact of a migration in opposite directions going on at the same time over the North Sea. This is observed more particularly at south-eastern stations, on light-vessels moored at many miles distance from the nearest land, where, during the spring and autumn, the same species of birds, as crows, rooks, jackdaws, starlings, larks, sparrows, buntings, and finches, are recorded crossing the North Sea, moving from opposite quarters and passing both towards the British coast and towards the Continent. This apparently abnormal movement in opposite directions is again indicated in the autumn and spring of 1884–5.

With very few exceptions, the vast majority of our British birds, such as are generally considered habitual residents—the young invariably, the old intermittingly—leave these islands in the autumn, their place being taken by others, not always necessarily of the same species, coming from more northern latitudes, or from districts of Eastern Europe, where, on the approach of winter, the conditions of locality and food-supply are found less favourable to existence. These immigrants on the approach of spring leave, moving back to the Continent on the same lines, but in the reverse direction to those traversed in the autumn; at the same time, also, our own birds return from the Continent to their nesting-quarters in these islands.

The notes under the head of separate species indicate several movements of special interest. Blackbirds have crossed the North Sea in extraordinary numbers, commencing on September 12 and throughout October, and immense numbers in November; on the 11th, 12th, and 13th the rush appears to have been continuous, night and day, over the whole coast line; after this intermittent to the end of the third week in January 1885.

Another very interesting feature is the occurrence of the Arctic bluethroat in considerable numbers between September 8 and 18; eighty to one hundred were observed in one locality on the Norfolk coast on the 12th.

The migration of the gold-crested wren was very pronounced. The first are recorded on August 28, and after this at various stations up to November 22.

It is rather remarkable that, with one exception (gold-crests seen inland in North-east Lincolnshire, on November 22, which may have arrived at an earlier date), the migration of this small species on the east and west coasts of England commenced at the same date, August 28, and also ended on the same date, November 16.

On the night of October 4, the time of the total eclipse of the moon, during the hours of greatest darkness, between 9 and 12 P.M., as observed by a member of the Committee,[1] gold-crests were striking the lantern of the Isle of May lighthouse. There is evidence also of other rushes of gold-crests at some of the Scotch stations during the hours of the eclipse. On the Irish coast the same night, at the South Maiden's lighthouse twenty struck at 10 P.M., and at Rathlin Island lighthouse the same number were taken at midnight.

Pied flycatchers arrived in large numbers from August 16 to September 17. Across Heligoland also there was a great migration between the same dates.

Reference is also made in the report to the great arrival of this species during the first week in May, 1885, observed at stations ranging from Yarmouth to the Pentland Skerries. At Flamborough the flycatchers arrived with a N.E. wind, and were accompanied by male redstarts. In their next report the Committee hope to be able to give full details of this remarkable immigration.

Immense numbers of ring-doves are shown to have crossed from the Continent between October 21 and the end of November. This immigration appears to have covered the coast between Berwick and Yarmouth; on our northern coast, for nine days, between November 20 and 28, the rush was continuous. Large numbers of stock doves also crossed during the same period.
